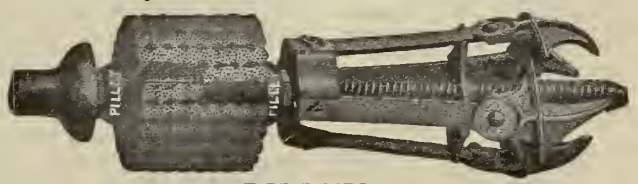
The Smart-Turner
Machine Co., Limited
HAMILTON, CANADA

The Simplest and best cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.

For sale by leading Canadian jobbers.
Manufactured by

PILLEY PACKING AND FLUE BRUSH MFG CO.
623 South Third Street - - - St. Louis, Mo
Eastern Office: 71 Fulton St., New York.

LADD WATER TUBE BOILER

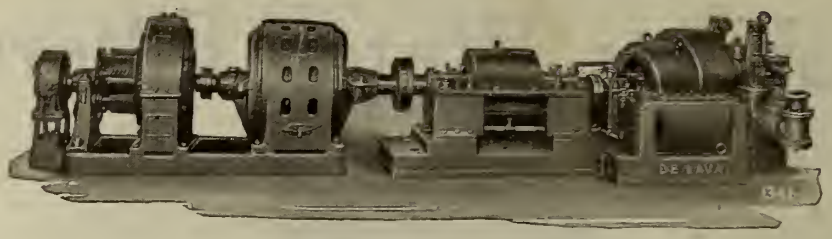
THE ARTHUR S. LEITCH CO Limited

1001-2 Kent Bldg., Toronto, Ont.

A UNIVERSAL POWER UNIT



This De Laval pressure-stage turbine uses either live steam from the boiler or exhaust steam from other units, and drives two generators, a 700-KW. alternator and a 200-KW. D.C. machine.

The turbine runs at the best speed for efficiency, while the generators are standard machines of 900-R.P.M., the speed transformation being made by a De Laval double helical speed reducing gear.

In De Laval steam turbines low bucket speed and liberal design are used throughout. The nickel steel forged shafts are very stiff, having a critical speed far above the operating speed.

In pressure stage turbines, monel metal is used for buckets because of its resistance to corrosion. Everything such as nozzles, steam chests, governor valves, etc., which may come in contact with superheated steam, is of cast steel.

De Laval steam turbines are designed for all steam conditions and for driving all kinds of machinery at all speeds and for the most economical means of transforming heat in steam into power.

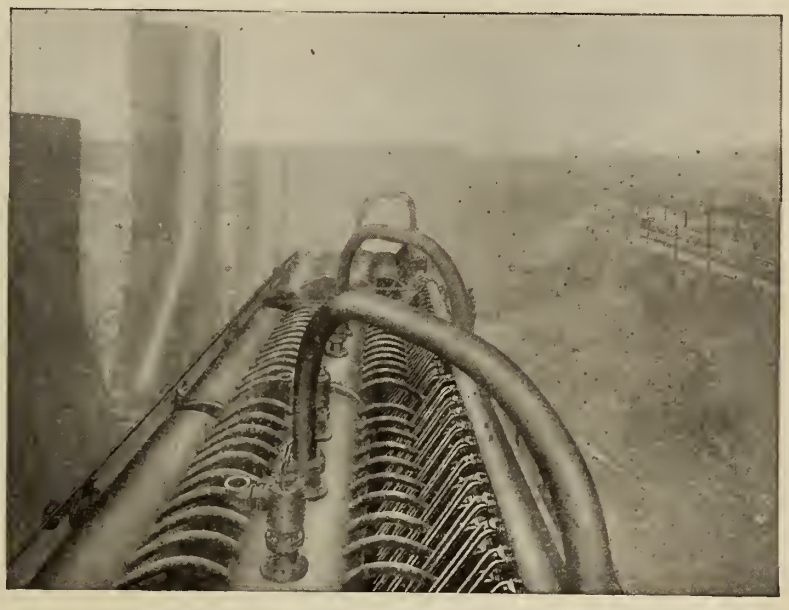
ELESCO SUPERHEATERS REDUCE POWER COST

ELESCO ADVANTAGES

The inlet of the saturated steam and the outlet of the superheated steam are located on opposite sides, to insure uniform steam distribution.



TYPICAL INSTALLATION of SUPERHEATER HEADER

POWER

An important but controllable item of manufacturing cost is that of power. Wheels must turn, machinery must move.
Power cost must receive the same attention and study as that given to labor, raw materials, overhead and other cost factors.
The power cost of a plant operating on saturated steam is excessive because it can be easily reduced.

Elesco Superheaters reduce power cost by saving from 10 to 20 p.c. of the fuel bill. Elesco Superheaters, like short-cutting operations, reduce manufacturing cost by reducing fuel cost. But there is this difference with the Elesco. When the Elesco has saved its cost in fuel (ordinarily in a few months) it continues to pay a steady return on the investment.

The Elesco is adaptable to all types and sizes of boilers.

What boilers do you operate?

TOO many manufacturers are buying steam Specialties for today when they should be buying them for tomorrow. In a comparative test the specialty which gives longest service wins. Of great import then is the fact that scores of Morrison installations dating back ten, twenty, even thirty years, are still giving accurate service with practically no repairs.

Order Fisher Specialties Through Your Own Jobber

Fisher Specialties can be quickly and easily ordered through your own jobber anywhere in Canada.

Type 1

Over forty years of successful operation under all conceivable conditions have given Fisher Steam Specialties an enviable record for accuracy, long-lasting satisfaction and low repair cost.

Fisher
Pressure Regulator
Series 90

is more than a reducing valve. It delivers exactly the proper amount of steam necessary to maintain the required heat in cooking kettles, rendering vats, vulcanizing tanks and all other classes of dead end service. It also shuts off absolutely all supply of steam when the process it is serving is suspended.

Series 90

Fisher Steam Trap
Type 33

will keep your steam lines absolutely free of all condensation. It insures your steam reaching its goal dry and hot. Valve is placed at the top of trap away from all possible dirt or other foreign impurities.

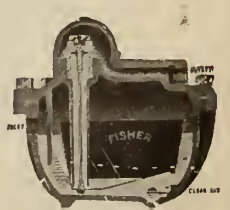
Intermittent discharge, eliminates wire-drawing and consequent steam leakage.

Fisher Pump Governor
Type 1

is especially designed for the automatic control of pumps working under pressure. Used on steam turbines, fire pumps, boiler feed pumps, air compressors, etc.

Automatically starts or stops a pump working under pressure and maintains a uniform pressure on discharge side at all times.

Like all other Fisher devices it is fully tested under actual working conditions



Type 33

These are just a few of the line of famous Fisher Specialties. We will be pleased to send you our complete catalog of Fisher Power Plant Specialties. It is an attractive book full of interesting information to Canadian engineers. Write for it today.

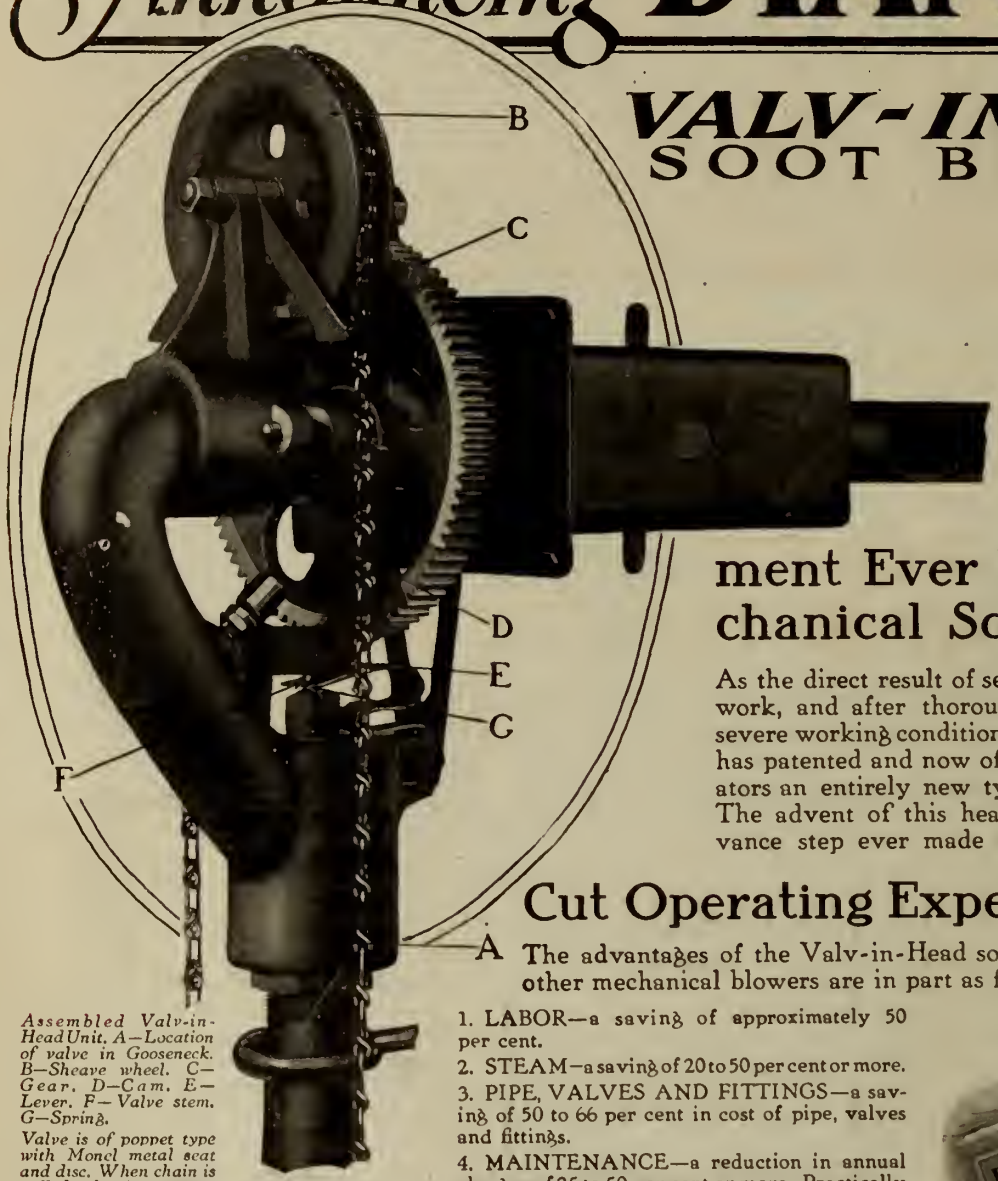
Announcing DIAMOND

VALV-IN-HEAD SOOT BLOWERS



Assembled Valv-in-Head Unit. A—Location of valve in Gooseneck. B—Sheave wheel. C—Gear. D—Cam. E—Lever. F—Valve stem. G—Spring.

Valve is of poppet type with Monel metal seat and disc. When chain is pulled valve is operated by Cam D and Lever E.

The Most Important Improvement Ever Made in Mechanical Soot Blowers

As the direct result of several years' experimental work, and after thorough tests under the most severe working conditions, the Diamond Company has patented and now offers to power plant operators an entirely new type of soot blower head. The advent of this head marks the greatest advance step ever made in the soot blower field.

Cut Operating Expenses in Half

The advantages of the Valv-in-Head soot blower as compared to other mechanical blowers are in part as follows:

1. LABOR—a saving of approximately 50 per cent.
2. STEAM—a saving of 20 to 50 per cent or more.
3. PIPE, VALVES AND FITTINGS—a saving of 50 to 66 per cent in cost of pipe, valves and fittings.
4. MAINTENANCE—a reduction in annual charges of 25 to 50 per cent or more. Practically complete elimination of condensate obtained.
5. EFFICIENCY—greater cleanliness of boiler assured.
6. CONTROL—steam may be intermittently discharged over two or more arcs in revolution. Arc or arcs of steam jets within boiler invariably cover exact predetermined limits. Speed at which blower element may be revolved is so controlled by reduction gearing as to make improper operation extremely unlikely. Unit provided with visible and audible signal to indicate valve open.
7. VALVE DESIGN—time of opening and closing exactly adjusted to soot blower operating conditions, being slower than the standard quick-opening valve and faster than the standard globe valve, thus solving a problem of long standing.

Diamond Valv-in-Head Soot Blowers are described and illustrated in detail in our new Bulletin 287. Write for your copy.

Ask for Full Information

Valv-in-Head blowers are adapted to all types of water tube boilers.

On request our service Engineer will go over your existing soot blower installation and advise whether it can profitably be replaced with the Diamond Valv-in-Head System. Ask for full information.

Diamond

SOOT BLOWERS - SAVE 4 to 8% FUEL

Waterous

BRANTFORD, ONTARIO, CANADA

Power & Heating Boilers

Proper steam production is essential in any power mill.

Waterous Boilers enjoy an enviable reputation for easy steaming and for economy in fuel consumption. The correct design of boiler settings is mainly responsible for this.

Whether you are burning coal, screenings, refuse, wood, sawdust, gas or oil, we supply settings that burn it with the least labor and with best economy.

We build Heating Boilers up to 72" x 16', Return Tubular Boilers for power use, up to 165 H.-P.; settings, single or battery, in brick or all-steel.

The Waterous Engine Works Co., Ltd., Brantford, Canada

Columbia Recording Thermometers now made with the New Time Punch!

With the addition of this ingenious little device to the Columbia Recording Thermometer you can now check up accurately on the operator who is responsible for maintaining a uniform temperature.

The Day-and-Night Chart gives you a true *record* of temperature variations—but the TIME PUNCH shows *whether or not the operator was watching the chart.*

The TIME PUNCH gives you absolute assurance, *for the first time,* that the man in charge of temperature control will inspect the chart at specified intervals. If he fails to push the button as instructed, you will know, by the absence of punch holes on the edge of the chart, that he has been delinquent. The operator who is indifferent, negligent or asleep at his post hasn't a chance against this small but highly efficient "silent sleuth."

Incompetency, too, is checked up by the TIME PUNCH. For if the chart indicates undue variations—and the punch holes show that the operator has noted them—*you know that he has not taken the proper steps to keep the temperature even.*

Columbia Recording Thermometers, Gauges and Tachometers are the only instruments fitted with this ingenious and highly valuable device.

Catalog H-33 gives full information about Columbia Recording Thermometers, as well as valuable information about increasing efficiency, reducing spoilage and cutting manufacturing costs. A copy sent free on request.

PLIBRICO JOINTLESS FURNACE LINING

Makes You Forget Your Furnace Troubles

After lining your boilers with PLIBRICO, forget them, for PLIBRICO means the end of worry.

It is a plastic material, easily installed, that when molded into baffles, bridge walls, side walls, and front-door arches makes a setting that is absolutely airtight and gas tight. Being jointless, there are no bricks to fall out or mortar to crumble.

After being baked and properly vitrified, PLIBRICO makes a furnace lining as solid as rock, and resistant to heat up to 3100 degrees F.

Try it, and end your worries.

Sold only in steel containers of distinctive appearance as shown below. Warehouse stocks carried at Montreal, Toronto, Winnipeg, Vancouver and Calgary.

Write for interesting book L-35 on Furnace Building.

YARWAY

Junior Seatless Valve
For Exceptionally Difficult Service

Embodying the same excellent features which have gained wide and favorable recognition for the popular Yarway Seatless Blow-off Valve, this new YARWAY JUNIOR SEATLESS VALVE is especially designed to give unusual service on

Water Column Blow-Downs
Gage Glass Blow-Downs
Soot Blowers
Turbine Drips
Superheater Drains
Steam Automobiles
Generators for Locomotive Headlights

and other difficult service where the ordinary seat or disc valve cannot be relied upon.

One of its most important advantages is the automatic regulation of pressure on the packing, controlled by the handwheel. After valve has closed, packing is tightened by turning hand-wheel. Before valve is opened pressure is first removed from packing. This Automatic protection results in unusually long life for the packing.

The YARWAY JUNIOR is made up in bronze, steel or iron, depending on the intended service.

Write today for celluloid sliding model, showing exactly how it works.

New Truths and Old Fallacies

Lubricating Quality—*Continued*

We try to keep Magnolia Metal at the peak of quality, and what we aim to furnish is quality and service, at a price much under that charged for Genuine or other high-grade babbitts, and at greater economy, however low the price of other grades may be.

Alleged Magnolia Metal formulas are published in every text book, as a part of its essential make-up, and is a distinction not accorded other similar proprietory brands. No two of these formulas are the same, unless copied, and in one instance, Doctor Dudley (deceased), then Chief of the Chemical and Test Department of the Pennsylvania Railroad, announced that Magnolia was composed of 83.55 lead and 16.45 antimony, with traces of certain impurities. Because of its authoritative source, this formula has been given wide publicity. As this was rather a good formula for competitors and copyists to follow, we have been content to let it go at that. Furthermore, as we have said before, we sell quality and service—not formula. Neither do we engage in a competitive scramble for business—we prefer to stay in our own class and hew to the line which we have always followed.

But we have not yet finished discussing the self-lubricating qualities of Magnolia Metal.

We always did realize the importance of this quality, and we knew that Magnolia possessed it, but the first high official confirmation of it was by the United States Government, in a most elaborate test made by three engineer officers at the New York (Brooklyn) Navy Yard.

(Continued next month).

SHEET PACKING

The modern tendency in engineering is toward higher pressures and increased superheat. No. 900 sheet packing has met this continued advance and given entire satisfaction under severest conditions.

Due to its high tensile strength, No. 900 gives lasting service on joints that are frequently broken, and under strainer box covers or handhole plates that are often removed.

No. 900 is equally adapted to steam, air, ammonia, acids, etc.

The Garlock trade-mark is your guarantee of reliability.

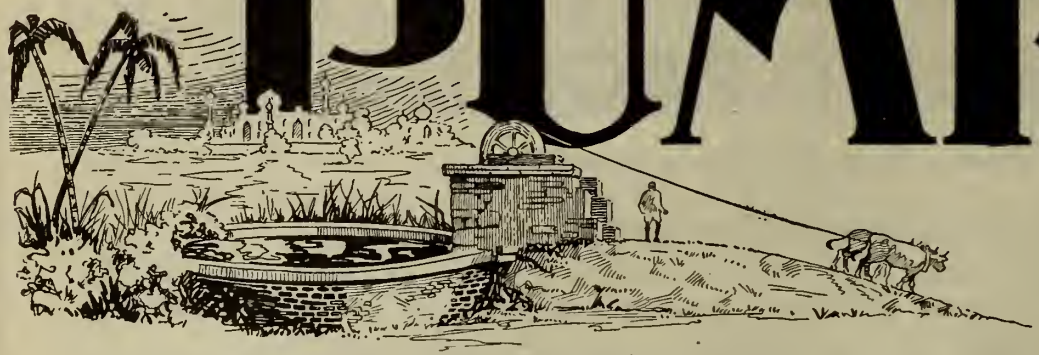
PUMPS



The ancient Indian Churras is a combination of rope, pulley, leather bucket, deep well, and a pair of oxen.

There was one good thing about the ancient Churras of India—it was reliable. The powerful oxen never seemed to tire. Every time they plodded down the hill they pulled from out the well a big bucket of water.

One of the many good things about American-Marsh Pumps is their absolute reliability. There are no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design.

Write for bulletins.

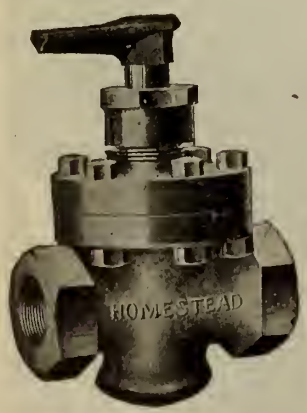
HOMESTEAD Quarter-Turn Valves

Stay Tight!

It is practically impossible to keep globe or gate valves tight for any length of time when the service is severe because the seating surfaces are always exposed and subject to pitting and cutting.



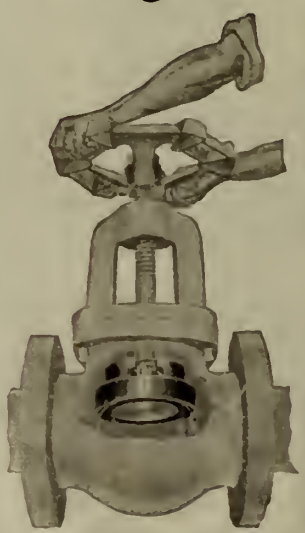
Homestead quarter turn Valves are seatless. They stay tight!

You can save yourself many a breakdown and many a shut-down by using Homestead Valves. They are guaranteed unconditionally and are rendering more than expected results to thousands of satisfied customers who back up their experiences by ordering more Homesteads whenever they require tight, efficient, durable, positive-acting valves.

Benefit by the experience of others. Give Homestead Quarter-Turn Valves a trial, and secure permanent satisfaction.

Homestead Valve Mfg. Company
Pittsburgh, Pa. : : Works: Homestead

Turn as hard as you can— They will not Break



A disc that breaks and drops from its holder not only causes a leaky valve but the loose parts as a rule clog the pipes and perhaps damage the pump or other apparatus to which the line is connected.
Be sure you specify **Pratt & Cady Renewable Disc Valves** because they are provided with asbestos discs with ample strength and heat-resisting properties.

P. & C. discs are of a fibrous structure—grade A asbestos, the longest fibre stock obtainable. These long fibres are closely interwoven, one with the other and firmly molded into a cohesive mass by the addition of a specially prepared binder.

Superheating

Regardless of Fuel Cost, Even Though it Costs Nothing, it Pays to Superheat With Elesco Superheaters

No matter what your fuel costs, even though it costs you nothing, it pays to apply Elesco Superheaters to your boilers. Instead of wet, lifeless steam, your engines or turbines receive an ample supply of superheated "power plus" steam.

Where fuel costs are high you can reduce its cost by burning less of it. All your operating conditions will be improved when you apply Elesco Superheaters. Your steam supply will be adequate even under increased power demands; your piping and engines will be protected from the dangers of water hammer. Turbine blade wear will be greatly reduced and reblading necessary only after much longer periods of operation.

These advantages result in lower operating and maintenance costs.

Let us explain how the Elesco Superheater will accomplish these results in your plant.

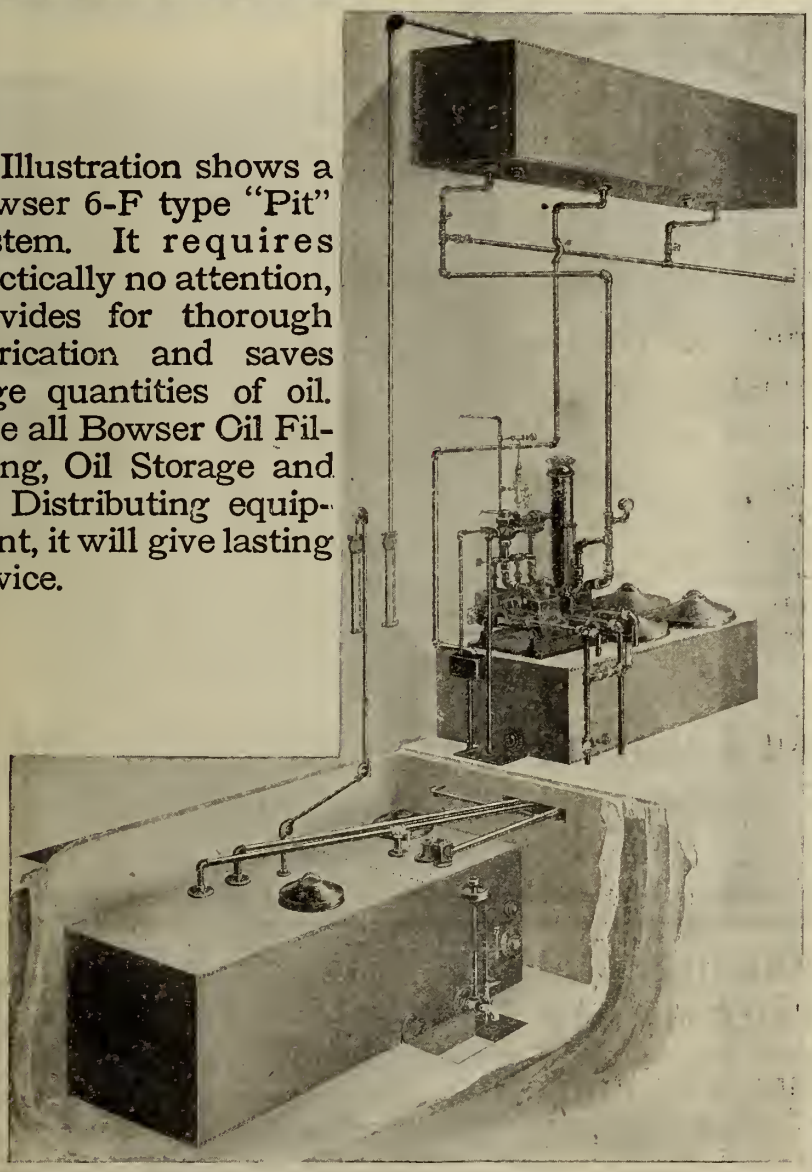
BOWSER OIL FILTRATION SYSTEMS

ESTABLISHED 1885

Illustration shows a Bowser 6-F type "Pit" System. It requires practically no attention, provides for thorough lubrication and saves large quantities of oil. Like all Bowser Oil Filtering, Oil Storage and Oil Distributing equipment, it will give lasting service.



provide the most efficient method of lubrication for rolling mill, gas or steam engines, for any moving part requiring lubrication.

The Bowser System provides plentiful lubrication at all times. It reduces the consumption of oil enormously by filtering and using the oil over and over. It increases production or power output by reducing friction and preventing breakdowns from worn out or burned bearings.

Let our engineers tell you of representative installations, suggesting how you can save by filtering your oil. Their co-operation and their experience is at your disposal.

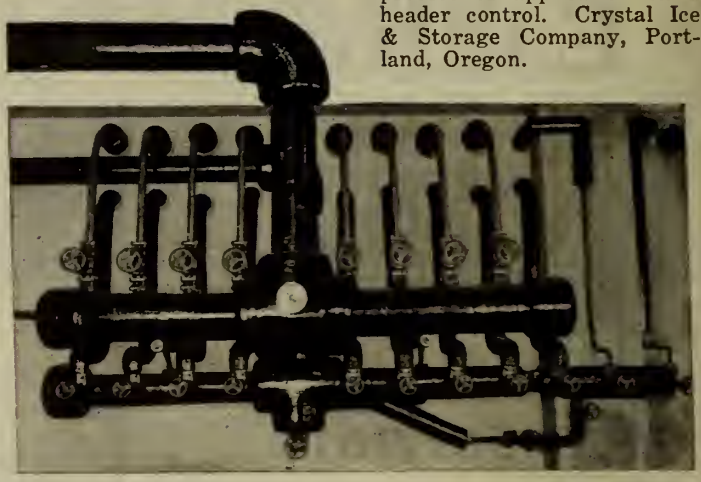
The Cost of Frost

It costs as much in *one year* to keep brine and ammonia lines covered with frost as it does to insulate them permanently with Nonpareil Cork Covering. In other words, Nonpareil Cork Covering saves in one year, or less, enough refrigeration to pay for itself.

Which, then, is economy: To *spend* a certain sum every year for pipe line losses, or to *invest* that same sum once in Nonpareil Cork Covering and get it all back at the end of the first year? The answer is obvious. It explains why you see Nonpareil Covering and not frost on brine and ammonia lines in economically operated plants.

Nonpareil Cork Covering is composed solely of clean, granulated cork. Its insulating efficiency is due to the myriads of minute sealed air-cells of which cork is composed. Densely compressed in molds, moisture-proofed internally by the liquefied gum of the corkwood and protected externally by a mineral rubber finish, Nonpareil Cork Covering is impervious to moisture and frost. Properly applied and given reasonable care, it "lasts longer than the pipe."



Nonpareil Cork Covering in process of application on a header control. Crystal Ice & Storage Company, Portland, Oregon.

Some remarkably interesting and valuable information on cold pipe losses and the savings effected by insulation is contained in the 64-page book, "Nonpareil Cork Covering." Write for a copy. There is no charge or obligation and you will find it well worth while.

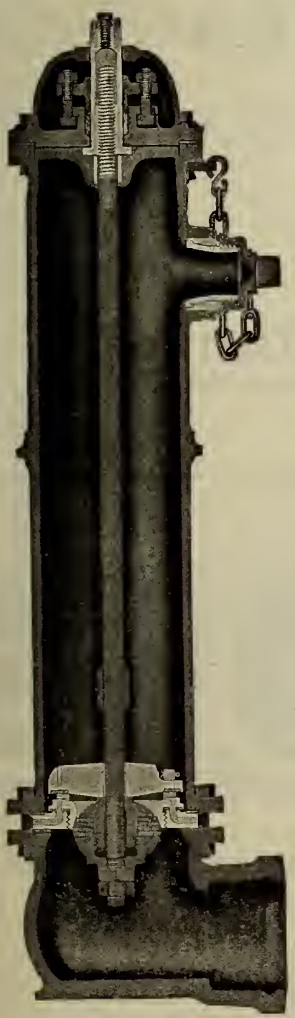
DARLING
PATENTED

The Perfect Hydrant for all Purposes

MADE IN CANADA



MADE IN CANADA

Some of the Qualities of the DARLING HYDRANT

COMPRESSION VALVE—Closes with the pressure and prevents water escaping should barrel be broken above valve.

LARGE BARREL—Delivers water to nozzles with no loss of pressure.

INTERNAL PARTS—*Including main valve and drip valve seats* easily removed through top of hydrant.

OPERATING THREADS—Are at top of hydrant, protected from injury and accessible for lubricating.

COMPRESSION DRIP—Dependable and cannot be clogged.

STUFFING BOX—Bolted pattern and cannot work loose in operating hydrant.

LENGTHENING HYDRANT—The only part required is an extension piece of the desired length.

VALVE ROD—Is in one piece and is free from torsional strain.

WORKING PARTS—Are made of bronze, excepting valve rod and it works in a bronze operating nut.

FLANGED CONNECTION—To hydrant base permits pointing the nozzles in any position.

VALVE—Is made of sole leather, the best material obtainable for the purpose.

BOTTOM OF BASE—Comes on level with water main and does not require excavation below main.

Some Notes on the Burning of Oil Fuel

Analyses of Various Fuel Oils—Air Required for Combustion—Disadvantages of Inferior Burner of Low Cost—Mechanical Systems—Speed in Raising Steam on Idle Boilers—Boiler Furnace Design—Refractory Material

By J. A. McGILLIVRAY

IT IS not the writer's intention to enter into a discussion of the merits or demerits of the various oil burners now in use. There are a great many types, and probably thousands of patents that will never see the light of day. But there are two general classes that may be referred to as high pressure or mechanical, and low pressure burners.

High pressure or mechanical burners are supplied with oil under high pressure, atomization is mechanically produced, and the low pressure burners are supplied with compressed air or steam for atomization. With either type it is absolutely essential for complete combustion that the oil be broken up into fine spray (atomized) so that the oil and oxygen required for its combustion may mix in proper proportions and freely unite.

Ordinarily, high pressure air or steam is preferable to low pressure, as the atomization is more complete, but with low pressure types good results have been obtained with light oils. For stationary boilers steam from the battery at boiler pressure is used. The steam supplied must be free from moisture, not necessarily superheated steam, but dry, saturated steam. If the plant is equipped with air compressors, there is an advantage in using compressed air instead of steam for atomization. In fact numerous tests have proven that the evaporation is from 6 per cent to 12 per cent better per pound of fuel when compressed air is used, but the air pressure must be reasonably constant and this must be taken into account when installing the unit. It may pay to put in a small independent compressor to supply the burners, as in ordinary compressor plants the air pressure may vary 10 to 15 pounds in as many minutes. The writer has had some annoyance with this feature of compressed air supplied from the main air compressors for atomization. The volume of air required for combustion is not supplied entirely through the atomizer, only sufficient to break the oil up into its atoms. The volume for combustion is supplied either by natural draft or low pressure blower. If compressed air is used the pressure should be from 70 to 90 pounds per sq. in. for a high pressure burner, using ordinary crude oil.

The oil is, or should be, heated on its way to the atomizer to a temperature near the vaporizing point. The vaporizing point varies for crude oil from 142 deg. Fahr. to 230 deg. Fahr., and light fuel oil 130 deg. Fahr. This heating oil is often conveniently and economically accomplished by running oil supply pipe through a heated space in the furnace brickwork. The oil pressure will vary with the gravity of the oil, and may be anything from a few pounds per sq. in. to 400 pounds, depending upon the system used, but as already stated the air pressure and oil pressure must be constant and reasonably steady in order to get satisfactory results. With high viscosity crude oil it will be necessary to heat the oil in the supply tanks sufficiently to reduce its viscosity so that it can be conveniently pumped.

Some analyses of fuel and crude oils are given herewith, through the courtesy of William Newton Best, author of the "Science of Burning Liquid Fuel."

Air Required for Combustion

Theoretically, the amount of air required for complete combustion of fuel oils varies with its chemical composition and is for average fuel oils 14 pounds per pound of fuel and in volume=about 190 cubic feet per pound of fuel. In best practice, however, there is always some excess air, and the efficiency of combustion may be considered good if excess air does not exceed 30 per cent of the theoretical, or 18 1-2 to 19 1-2 pounds per pound of fuel.

Considering that the efficiency of the furnace begins to fall off rapidly with excess air over 30 per cent and that 100 per cent excess air is common, it is very important to have the settings airtight and the supply of air to the furnace under control through the proper channels, as the air that infilters through the settings does not properly mix with the fuel.

The aid of a gas analyser is essential in determining excess airs—and since it is highly important that the operator should know definitely at all times the amount of excess air being admitted a hand analyzer or portable set is unsatisfactory, as he has definite information for only the instant that the gas sample was taken. Also a great deal depends on the person taking the sample, and his knowledge of the instrument. It would therefore ap-

pear that a good recorder or indicator is really a necessity.

A study of the appearance of the flame is also of valuable assistance. It may be said that an experienced man can judge the amount of excess air pretty closely by studying the color of the flame. The following from Sterling's Marine Engineers' Handbook may be interesting:

"If the flame is incandescent white, and the furnace walls are clearly discernible through it there is considerable excess air present. As the percentage of excess air is reduced the color of the flame at the rear end of the furnace becomes a pale yellow, then yellowish orange and orange red. In general with an efficient installation operating under a minimum of excess air, the ends of the flame farthest from the atomizers are a yellowish orange, or golden shade. The gases of combustion are colorless and the seams in the brick are just discernible.

"At very high rates of combustion, when the flame completely fills the furnace, temperatures preclude the presence of these temperature colors. An incandescent dazzling white still indicates excess air, but a reduction in this excess is only indicated in the furnace by a softening in the intensity of the white flame."

Observation of the smoke pipe or chimney may be entirely misleading. A perfectly clear smoke pipe or chimney may mean only a small amount of excess air or it may mean as much as 300 per cent excess.

A clear smoke pipe is ideal when the gas analysis at the same time shows that there is high CO_2 very low O_2 and no CO. For example 14.7 CO_2, 0.8 O_2 and no CO.

It is well to remember that the presence of smoke does not always mean insufficient air or high CO. (1) an inefficient installation, (2) poor atomization; (3) poor mixture of air and oil; (4) unconsumed oil striking cooling surfaces and (5) poorly designed furnace frequently cause smoke when the air used for combustion may be far in excess of that required.

By far the most common causes for low efficiency are probably "poor mixture" and infiltration of air through the settings. The latter can be prevented by keeping the settings in good repair, and applying a coating of non-infiltration or other insulation. The former can only be improved by the installation of a good atomizer and proper control of the air supplied for combustion.

The great importance of properly mixing the air and oil may be more clearly demonstrated by another reference to Best's "Science of Burning Liquid Fuel."

"Considering that air contains 20.7 parts oxygen and 79.3 parts nitrogen at 62 deg. Fahr., one pound of air occupies 13.41 cubic feet. If the temperature is increased to 100 deg. Fahr. this air occupies 14.096 cubic feet. Theoretically it requires 13 1-2 to 14 1-2 pounds of air to effect perfect combustion of 1 pound of oil. Allowing 14 pounds at 62 deg.

Fahr., it would require 183.97 cubic feet of air to effect perfect combustion of one pound of oil or at 100 deg. Fahr., it would require 197.34 cubic feet of air. In practice it requires 17 1-2 to 19 1-2 pounds of air to effect complete combustion of a pound of oil.

"Allowing 19 pounds of air at 62 deg. Fahr. This air occupies 249.68 cubic feet or at 100 deg. Fahr. it occupies 267.8[2] cubic feet. Allowing a gallon of oil to weigh 7 1-2 pounds, it requires 19 × 7 1-2 = 142 1-2 pounds of air to effect the combustion of one gallon of oil, or 1872 cubic feet of air at 62 deg. Fahr., or at 100 deg. Fahr., it will require 2009 1-4 cubic feet of air to effect complete combustion of a gallon of oil."

Now, to make it still clearer, let us consider Mr. Best's statement in terms of volume of air to volume of oil, remembering that the oil and air must be mixed freely and thoroughly.

A gallon of oil contains 231 cubic inches. The proportion of air to oil must then be, when the temperature is 100 deg. Fahr.

(2009.25 × 1728) to 231, or

$$\frac{2009.25 \times 1728}{231} = 15030.23$$

or with every unit of oil at 100 deg. Fahr. there must be mixed 15030.23 volumes of air at the same temperature, or in other words, the oil must be broken up by the force of the atomizing agent into approximately

$$\frac{1}{15030}$$

of its volume at the point where it issues from the oil feed nozzle. This is not dependent on any part of the installation at a whole, but entirely on the atomizer itself, its ability to break the oil up into its atoms. This is why some of the home-made burners to be found in use are extravagant and some of them are not worthy of a moment's notice.

Looked Good—But a Failure

Their first cost is low, to be sure, but their efficiency is zero. They can spray oil into the furnace in a fine mist, but they are not atomizers. A few of the home-made kind came to the writer's

FIG. 3. — Showing Results of Tests on a Babcock & Wilcox Boiler Under Natural Draft at Moderate Atomiser.

notice a few years ago. One of them invented by a combustion engineer of very high standing gave promise of being a success on small rivet heating furnaces, and also on long torpedo furnaces. The degree of attention that it attracted at the time was entirely due to the fact that the inventor was considered at that time a pioneer in the development of oil burners and pulverized coal burners. His atomizer was low in first cost and could be built out of pipe fittings; his theory was correct, but his patent burner as a commercial article, was a miserable failure. I have no doubt had he lived to carry his theory out in another burner he was contemplating he would have succeeded, as he had the theory of combustion down better than any man with whom I have been personally acquainted before or since. I have recently seen modifications of this burner that were being introduced by another who did not have the advantage of combustion engineering experience, but who was a pretty brainy draftsman. He succeeded in making the original burner more complicated, more expensive, but on the whole much inferior, as an atomizer, to the original article.

Some day some one who has some combustion theory and experience and some drafting ability, and a little imagination left over, will develop an oil burner that will automatically control the oil, air supply and steam pressure, and maintain exactly 14 per cent CO_2, while we sit back and read the moving picture magazine—well, why not—and possibly the manager would pay for the magazine again—why not? It would pay the manager to buy magazines for some firemen I met in my time and keep them away from the fire door once in a while.

Mechanical Systems

The pressure of mechanical systems differs from the compressed air or steam atomizers in that the oil is atomized by being forced through the atomizer at a high pressure. That is, the oil supply is under high pressure, which forces the oil through the system. The pressure varies with the gravity of the oil, and is such that the oil is forced through the atomizer at a high velocity, thus breaking it up. The oil is heated to about the vaporizing point by passing through a heater. The air for combustion is supplied through tuyeres or air registers on the boiler fronts or checker work.

Stationary coal burning boilers are sometimes partially equipped with oil-burning apparatus, to supplement the coal fires in case of sudden demand for peak loads. The economy of coal operation is not impaired in any degree. The oil burners are placed on the side of the boilers and are instantly available. In some plants ordinarily under coal fires using stokers boilers may be equipped with oil burners on swivels so that they can be swung from position at the side of the boiler and thus play their fire over a green bed of fuel. When the coal bed has been ignited the oil burner is swung out of position and the opening in the front closed up. This is a great advantage in quick starting or with coal that is hard to ignite on a chain grate.

It would appear to be of great advantage in stationary plants that are subject to large peak loads at certain hours of the day, to have a few boilers in the battery equipped with oil burners, instead of banking fires. Banking is somewhat costly and more or less unsatisfactory as it requires a longer time to get banked fires worked up than to get an oil furnace hot.

Will Take 10 Minutes

As boilers under banked fires (short bank) are seldom cut out of the line—unless they are equipped with non-return valves and cut themselves out—they are always hot and no serious results are encountered by forcing them into service quickly. The advantage of oil burners on some of the battery can be appreciated. Economy is not always a factor when an emergency calls for more boilers in the line. A boiler kept hot, that is, not connected in the line but with hot water constantly circulating through and having a gas pilot light burning can be put into service at 150 pounds steam in ten minutes.

The following tests made at the Naval Fuel Oil Testing Plant, Philadelphia, show somewhat higher efficiency than might be expected from good W. T. boilers with coal fired stokers. The evaporation per pound of oil is from 15 to 17 pounds, with an average not far from 16 pounds. The evaporation per square foot of heating surface is high, the boiler and furnace efficiency falling off as the draft pressure and the evaporation per square foot of heating surface are increased. The efficiency falling off about 1-2 per cent, while the evaporation per square foot of H.S. is increased 230 per cent, the eq. evaporation per pound of oil falling off 10 per cent. The efficiency is highest when the equivalent evaporation per pound of oil is about 16 pounds, and the equivalent evaporation per square foot of H. S. about 5 pounds. It will be seen by referring to the above charts that what is

true of coal fired installations is also true of oil burning installations. High ratings are attainable only at the price of efficiency. However, there are other factors that largely determine the choice of installations, whether they shall be coal or oil, and which will not be discussed here, but it may safely be stated that oil is now a strong competitor of coal in stationary, locomotive and marine plants. Oil installations are even now putting in their appearance, almost at the mouth of the coal mines, and are at present attracting considerable attention from power plant engineers.

Boiler Furnace Design

The ideal conditions for furnace design are as follows:

1—Sufficient furnace volume for total oil burned at the designed rate of combustion, which maximum may be taken as .75 pounds of oil per sq. ft. of H. S. per hour in water tube boilers of large size, and the average may be stated to be .6 pounds per sq. ft. H. S. furnace volume.

The furnace volume should be 1 cu. ft. for every five pounds of oil burned per hour, for example—

A W. T. boiler, having 6000 square feet of H.S., the maximum rate of combustion .75 pounds per square foot of H.S., the volume of the furnace should be

$$\frac{6000 \times .75}{5} = 900 \text{ cu. ft.}$$

2—The maximum of refractory surface to assist in maintaining a high furnace temperature.

3—Increase of cross sectional area of the furnace with the expansion of the gases.

4—Minimum area of cooling surfaces close to the flame tending to reduce the furnace temperature.

5—Walls and tubes sufficiently remote from the burners to permit of complete combustion of oil before coming in contact with them.

6—A minimum of infiltration of air except through the proper channels.

7—Exit of the gases of completed combustion at a maximum distance from the burner.

Refractory Material

Poor fire brick should never be used as it is disappointing to both the builder and owner of the furnace. It takes as much time and labor to construct a furnace of poor fire brick as of good. Poor brick is dear at any price, no matter what may be the fuel used.

The excessive heat which can be obtained from liquid fuel makes it necessary in many instances to use a very superior grade of fire brick. These bricks must be non-expanding. Ordinary silica brick is not suitable for extremely high furnace temperature.

The analysis of brick for crucible furnaces is as follows:

Silica	56.15%
Alumina	33.925%
Peroxide Iron	0.59%
Lime	0.15%
Magnesia	0.115%
Water and inorganic matter	9.68%

In ordinery boiler furnaces it is not necessary to use such good quality of brick. It is, however, essential that the bricks do not expand or contract excessively.

Practical Requirements

The following instructions cover the putting into service and the operation of oil burners in a general way. They should be a guide for the fireman or operator who may have oil burning apparatus on his boilers or furnaces and whose duty it is to get the best results attainable. These instructions might well be written in every engineer's note book, whether he has to do with oil burning apparatus or not, at the present time, he may later on.

The oil must be finely atomized just prior to coming in contact with the air for combustion. The requisite quantity of air must be intimately mixed with the oil and excess air reduced to a minimum. A high furnace temperature must be maintained, by the use of sufficient refractory surface, to assist complete combustion.

Combustion must be completed before the combustible gases come in contact with the cooling surface and become chilled below the ignition temperature.

Boiler heating surfaces must be protected from localized heating caused by blow pipe action; heating should be uniformly distributed.

Before Lighting Fires

Ensure that the whole system is clean and free from dirt, waste, flakes of shellac, red lead, etc. Inspect and clean all strainers. This should be done frequently while under way. See that the wire gauze is in good condition and that the proper mesh is used. Thoroughly clean the atomizing tips, place and properly adjust same in air registers. Close individual atomizer throttle valves. Drain the water in the oil tanks that has separated and settled in the bottom.

If the oil is very cold and viscous, and the pumps have difficulty in getting a suction, use heating coils provided in the tanks. If air chambers are provided, drain and charge with compressed air.

Start up the pumps and put oil pressure on the lines. Inspect for oil leaks. If there is a meter provided in the oil line by-pass it until ready to light up, otherwise it will operate while air is being pumped out of the line and while oil is being circulated. Warm the oil with the heater. See that torch is ready. If light oil is being used, everything is in readiness for lighting the fires as no trouble is experienced in atomizing oils about 23 deg. Baume at the usual temperatures. When no steam is available a hand pump may be used, or motor driven auxiliary, where available in stationary plants.

A suitable lighting torch may be made by securing a few loose turns of asbestos wicking on the end of rigid wire rod.

Dampers should be wide open before fires are lighted.

Lighting Fires

Note that there is sufficient pressure on the oil and that it is at the proper temperature for good atomization. Light the torch and place near and just under the atomizer. Stand clear as a precaution against blow backs. Open the atomizer throttle and the oil will immediately light up and readily burn. Be sure to note that the oil is being properly atomized. A dirty atomizer will cause heavy black streaks. The presence of considerable water is indicated by sputtering, that is easily detected.

Every precaution should be taken to prevent unburned oil from collecting in the furnace, as the hot brick gasifies it and there is serious danger of a violent explosion.

When extra burners are lighted, it is preferable to use the torch each time while the furnace is still relatively cold. After steam is generated and the furnace is hot, additional burners may be safely lighted from adjacent burners in operation.

No matter how hot the furnace may be, if all the burners are temporarily secured, do not attempt to relight from incandescent brick work. The most serious accidents have been occasioned by this practice.

It is not advisable to raise steam too quickly as it is not only injurious to the boiler but it is hard on the refractory lining tending to spall and loosen the brick.

In special cases, such as some types of marine boliers on special craft and on fire engines it is permissible to raise steam rapidly, but with ordinary stationary or marine in ordinary operation it is bad practice and inexcusable.

Pressure on Oil

The oil pressure does not enter into the problem of burning different oils. The question is purely a matter of ascertaining the temperature requisite in the case of each grade of oil to obtain the proper viscosity. When this viscosity is maintained the oil pressure may be the same with every grade of oil. With atomizers properly designed and kept properly cleaned oil pressures from 125 to 250 pounds give practically equally good atomization. Increasing the pressure above 125 pounds merely increases the capacity which, other things being equal, is very nearly proportional to the square root of the pressure, i.e., to double the capacity, "the viscosity and the size of the orifice remaining the same," four times the pressure is required. With increased capacity the air pressure must also be increased.

Heavy Soot on the Tubes

Heavy deposit of soot on the tubes always accompanies smoking, no matter what kind of oil is used, and is a sure sign of incomplete combustion. This condition is exaggerated under natural draft and at low air pressures and may be due to several causes—insufficient air for combustion, poor atomizers, oil too viscous, atomizers improperly adjusted, poor design of installation, unstrained oil, etc.

Carbon on Atomizing Tips.

Carbon on atomizing tips is the surest sign of their improper location. If the

atomizer is shoved in too far, an eddy is formed in the entering air currents.

A fine fog of oil is drawn behind the face of the tip and is deposited on this face, on the side of the tip and occasionally for some distance back on the burner pipe. This latter is an extreme case, when the atomizer has been shoved in several inches beyond the proper point. In extreme cases jets of ragged flames are also drawn back by this eddy, sometimes completely hiding the tip from view.

Carbon on Furnace Openings

If carbon forms on the edges of the furnace openings, the atomizers have been drawn back too far, or as is often the case, the furnace opening is irregular due to patching up of the brick work, and edges of brick or mortar project into the outer film of the cone of oil. If carbon forms on atomizing tips and also on furnace opening and there are no mortar or brick projections, the opening has been reduced to such an extent that the burner cannot be drawn back far enough to prevent eddies in the air currents described above. This is a fault of design and can be eliminated by increasing the furnace opening or by a new design of air register.

Hard Deposits on Tubes and Furnace Sides and Bottom

Hard deposits on tubes and on furnace sides and bottom are due to the oil striking the tubes or brick before it has time to burn. This is caused by faulty design or operation.

Under faulty operation the causes are the same as those that produce excessive smoke and soot. These are the failure to obtain proper mixture of the entering air and oil, at the register. This is more often caused by improper location of the atomizing tips than anything else. It is sometimes due to too much excess air entering around the cone of oil and thereby cooling the flame down so that combustion is not obtained until some distance in the furnace. This permits the angles from the axis of the tip to strike particles of oil thrown off at the greater the furnace bottom, side walls, or tubes near the front of the furnace before they are burned. This cools them below the combustion temperature. The lighter gases vaporize and burn, the carbon remaining adheres to the surface as a solid.

The noticeable increase in the amount of carbon deposits when viscous oils of asphaltic case, such as Mexican and Californian, are burned, is probably due to the large proportion of unsaturated hydrocarbons contained. These are heavy and slow burning. Other things being equal, they require a longer time in which to become completely consumed. Therefore they require a longer combustion or some means must be resorted to that will hasten combustion. This can be accomplished by increasing the velocity of the entering air for combustion. The area of the openings in the air controlling registers must be closed a proportional amount so that the volume remains the same. It is frequently stated by engineers that more air is needed to burn Mexican oils. This is not correct, and should be stated as follows: A greater pressure is required to burn Mexican oils, as an increase in pressure is necessary to obtain an increase in the entering velocity.

Water Power Resources of Canada

DURING the past two years there has been under way in the Dominion Water Power Branch a careful re-analysis and computation of Canada's water power resources. All existing stream flow and power data, available from Dominion and Provincial sources, have been systematically collated, analysed and co-ordinated with a view to preparing on a uniform basis from coast to coast, revised estimates of the power available. While the analysis is not yet finally completed, sufficient progress has been made to warrant the publication of the figures herein.

The total available and developed power resources are presented in a manner not heretofore adopted. A consideration of the figures will indicate that they place the water power resources of the Dominion in a much more favourable light than have previously published compilations.

While the resources have been exhaustively analysed in so far as the information available will permit, it should be kept in mind that only very meager data are to hand in many districts and for many rivers.

Basis Of Computation

The figures listed in the accompanying table and diagram are based upon rapids, falls and power sites of which the actual existent drop or the head possible of concentration, is definitely known or at least well established. Innumerable rapids and falls of greater or lesser power capacity are scattered on rivers and streams from coast to coast which are not as yet recorded, and which will only become available for tabulation as more detailed survey work is undertaken and completed. This is particularly true in the more unexplored northern districts. Nor is any consideration given to the power concentrations, which are feasible on rivers and streams of gradual gradient, where economic heads may be created by the construction of power dams, excepting only at such points as definite studies have been carried out and the results made matters of record.

In brief the figures hereunder are based on definite rapids, falls and power sites, and may be said to represent the minimum water power possibilities of the Dominion.

The power estimates have been calculated on the basis of 24-hour power at 80 per cent efficiency on the basis of "Ordinary Minimum Flow" and "Estimated Flow for Maximum Development." The "Ordinary Minimum Flow" is based on the averages of the minimum flow for the lowest two consecutive seven day periods in each year, over the period for which records are available. The "Estimated Flow for Maximum Development" is based upon the continuous power indicated by the flow of the stream for six months in the year. The actual method to determine this flow is to arrange the months of each year according to the day of the lowest flow in each. The lowest of the six high months is taken as the basic month. The average flow of the lowest seven consecutive days in this month determines the maximum for the year. The average for such figures for all years in the period for which data are available is the estimated maximum used in the calculation.

The estimated maximum development is based upon the assumption that it is good commercial practice to develop wheel installation up to an amount, the continuance of which can be assured during six months of the year, on the assumption that the deficiency in power during the remainder of the year can be profitably provided from storage or by the installation of fuel power plants as auxiliaries. The correctness or otherwise of this assumption for any particular site can only be definitely settled by the careful consideration of all circumstances and conditions pertinent to its development. The method, however, enables us to make a fairly satisfactory overall estimate of the maximum hydraulic power available, as distinctive from the estimated ordinary minimum power available.

Available And Developed Totals

The recorded power available throughout the Dominion, under conditions of ordinary minimum flow and within the limitations set out in the foregoing, is 18,255,000 h. p. The water power available under estimated flow for maximum development, i. e., dependable for at least six months of the year is 32,076,000 h. p.

There are installed throughout the Dominion water wheels and turbines to the extent of 2,271,000 h. p. However, it would not be correct to place this figure in direct comparison with the minimum or maximum available power figures quoted above and therefrom deduce the percentage of the available water power resources developed to date. An allowance must be made for the average ratio between the water wheels installed and the power available.

An analysis of the water power plants scattered from coast to coast, concerning which complete information is available as to turbine installation and satisfactory information as to stream flow, gives an average machine installation 30 per cent greater than

(Continued on page 37.)

The Treatment of Boiler Feed Water

Correcting Bad Water—Determination of Hardness, Scale, Foaming and Priming, Corrosion—Sources of Water Supply—Condensate—Requirements of Ideal Water Purification Plant

By ROBERT JUNE

HAVE YOU ever visited a salt plant? If so, you must have watched with interest the processes of evaporation in the salt pans. The brine enters the pans as a clear liquid, but as soon as heat is applied, the water begins to disappear in steam, and the salts are deposited. As you watched the deposits of salts increase, did it occur to you that an identical process to that going on before you was constantly going forward in your boilers?

In the case of the boiler the entering water is not loaded with the same high percentage of salt, to be sure, but the quantity of impurities is higher than is generally appreciated, and when you consider that there are literally many tons of water evaporated in the average boiler every day, and all the various salts and other impurities carried into the boiler remain until some definite action is taken to effect their removal, the fact becomes apparent that in dealing adequately with the impurities in water, we have a problem of real magnitude.

The importance of boiler water treatment is indeed not generally realized, because the size of the operating losses resulting from failure to remove or neutralize impurities in the feed water is not understood. These losses are caused by the formation of scale which reduces boiler efficiency and capacity, and by the pitting and corrosion of boiler tubes, which makes necessary their replacement.

In addition to causing scaling and corrosion, bad water causes foaming or priming. These troubles are self evident. There are other troubles, however, which are due to bad water and which are not so apparent. The good or bad condition of pump valves, and connection and feed lines, is largely dependent upon the quality of the water used, a fact which becomes evident when we suddenly lose the feed to a boiler, and perhaps the boiler or a good part of it. Nor do we always directly connect the breaking of a piston rod, cross head, or cylinder head with excess causticity or precipitates mixed with steam. Other losses which may often be traced to bad water are gradually increased steam consumption, excessive wear on packings and moving engine parts, and increased lubrication.

While these losses may not always be directly traced back to boiler feed, it is a fact that when our water is constantly purified there is very much less likelihood of these troubles occurring.

Correcting Bad Water

The neutralization or elimination of impurities in feed water may be effected by one or more of the following methods:

1—By chemical means.
  (a) Boiler compounds.
  (b) Water softening plants.
2—By mechanical means.
  (a) Tube cleaners.
  (b) Blow off.
  (c) Filter plants.
3—By thermal treatment.
  (a) Feed water treatment.
  (b) Distillation plants.

Before discussing these means of removing trouble, let us inquire further into the sources of our difficulties. We find that our troubles and their causes are as follows:

Scaling—Caused by the presence of sediment, mud, clay, readily soluble salts, bi-carbonate of magnesia, lime, iron, sulphate of lime, organic matter, etc.

Corrosion—Caused by the presence of grease, organic matter, chloride or sulphate of magnesium, sugar, acid, dissolved carbonic and oxygen, and also by electrolytic action.

Priming—Caused by the presence of sewage, alkalis and carbonate of soda in large quantities.

F. J. Crolius, steam engineer of the Carnegie Steel Co., classifies the various inorganic impurities in the manner shown in Table 1.

—By chemical means.

With the addition of chlorine, the combination given in the table cause most of our troubles. It is evident that the causes of so-called permanent hardness fall entirely within the sulphate range, and as a matter of fact most of our efforts must be directed towards the reduction of sulphates.

The principal scale forming offenders, $CaSO_4$ and $MgSO_4$, are non-corrosive, and the simplest procedure is to convert them to $NaSO_4$ and Ca or Mg carbonates, which are insolubles, by the addition of sodium. The sulphates of iron, aluminum and copper are usually so low that they can be ignored. This is fortunate as their removal usually requires expensive treatment.

Determination of Hardness

A 100-cc (cubic centimeter) sample of water to be tested is put in a 250-cc bottle, and a standard soap solution (this may be obtained from chemical dealers) run in 0.2 cc at a time, the bottle being shaken vigorously after each addition of the soap solution. Finally a lather is produced that will persist for at least five minutes, and then the volume of the soap solution used in cc. gives the degrees "U.S." hardness. One degree "U. S." hardness is equivalent to 1 grain of calcium carbonate per U. S. gallon (1 part in 58, 349.)

Professor Gebhardt employs the following factors for specifying the hardness of water in terms of calcium carbonate per U. S. gallon:

Magnesium carbonate	x 1.19
Magnesium sulphate	x 0.833
Calcium sulphate	x 0.735
Magnesium chloride	x 1.05
Calcium chloride	x 0.901

=hardness as calcium carbonate, grains per U. S. gallon or U. S. degrees.

It is impossible to judge the quality of feed water merely by the grains of solids per gallon since a large amount of soluble salt such as sodium chloride will not be as deleterious as a very small amount of calcium sulphate.

The scale of hardness usually accepted (grains of dissolved salts per U. S. gallon) is as follows: soft water, 1 to 10; moderately hard, 10 to 20; very hard water, above 25.

The following is a rough rating according to the number of grains of incrusting solids per United States gallon:

Less than 8 grains	very good
12 to 15 grains	good
15 to 20 grains	fair
20 to 30 grains	bad
Over 30 grains	very bad

This applies to calcium carbonate, magnesium carbonate, and magnesium chloride. For water containing sulphate of calcium and magnesium, divide the first column by four for the same rating.

The limiting factor in deciding whether a water carrying a large amount of soluble salts may be used for boiler feed purposes is the amount of blowing down necessary to keep the degree of concentration within the limits found by experience.

By the use of proper methods we may accomplish the complete removal of permanent hardness, oil, grease, and suspended matter, and may neutralize all their acids. The feed water may be so purified as to contain less than 1 1-2 grains per gallon of hardness due to calcium carbonate and magnesium hydroxide. The total of encrusting substances including silica, may be so reduced as to be less than 2 grains per gallon. This is the standard of purification which can usually be obtained and towards which we should work.

Scale

The character of scale varies from that of a porous, friable crust, to a dense, very hard coating. The amount of impurities present in the water cannot be used as a basis for pre-determining the amount of scale which will be formed, as this depends on the type of boiler, rate of driving and the nature of the scale forming ingredients.

In Table II. we have the results of a

number of tests made on locomotive boiler tubes with different thicknesses and character of scale. The variations in conductivity show the futility of basing any calculations on the thickness of scale. Thus test No. 1 shows a decrease of conductivity of 9.1 per cent for a scale 0.02 in. thick, while No. 16 shows a decrease of only 6.75 per cent for a scale over 6 1-2 times as thick. In each case the scale was even, hard and dense.

Influence of Scale on Heat Transmission

No.	Thickness of scale, inches	Character of scale	Dec. in conductivity, due to scale Per cent.
1	.02	Hard, dense	9.1
2	.02	Hard	2.02
3	.033	Soft	4.3
4	.033	Very hard	3.5
5	.038	Medium	4.03
6	.04	Soft, porous	6.82
7	.04	Hard, dense	3.07
8	.042	Very soft	9.54
9	.047	Hard	2.75
10	.065	Medium	2.39
11	.07	Soft	2.38
12	.07	Hard	4.43
13	.085	Soft, porous	19.0
14	.089	Very soft	4.95
15	.11	Hard, porous	16.75
16	.13	Hard, dense	6.75

The presence of scale, however, does cause material reduction in the heating surface, and in the volume of water held in the boilers. Thus a 4 in. boiler tube when clean, has an internal area of 141 square inches per foot of length, but should this tube become lined with one quarter inch of scale its area per foot of length is reduced to 122 square in. We thus find that a quarter inch of scale reduces the actual heating surface by about 11 per cent, and the volume of water by about 12 per cent. Furthermore the reduced area of the tubes tends to retard circulation.

Overheating of boiler tubes is the result of the presence of scale. When the deposit is heavy the tubes in the hottest passes of the boiler may become so hot that the pressure will bulge the metal to such an extent that the burst tube has the appearance of having been drawn. Overheating, even to a moderate degree, may cause gradual crystallization of the steel so that it eventually becomes brittle and can be broken like ordinary castings. The bursting of tubes is one of the most dangerous factors connected with the operation of water tube boilers and as it can always be traced to the presence of scale or oil on the internal surfaces, it follows that from the standpoint of safety and economy such conditions should not be tolerated.

Foaming and Priming

When foaming occurs it can usually be traced to the presence of one or more of the following impurities: Emulsified oil and grease, soluble organic matter, and silt in suspension. It may, however, be due to improper methods of handling the boiler, such as irregularities of load, improper firing and feeding, neglect to make periodic changes of water within the boiler, or to improper design of boiler, wrong arrangement of steam piping, incorrect water spaces or steam liberating area.

It is frequently claimed by operating engineers that the direct cause of priming and foaming in boilers is the presence of sodium salts in the feed water, and, of the sodium salts, sodium carbonate or soda ash, is the one most often charged with causing foaming. The trouble in such cases, however, is not due to the soda ash, but to the wrong application of it. It will usually be found that where foaming occurs with soda ash, no provision is made for the removal of precipitates formed by its reaction with the scale forming substances in the water. The result is the water becomes so befouled with impurities that priming and foaming occur.

Foaming may be caused by the introduction of soda ash in an open heater, which receives more or less animal oil with the exhaust, and the mixture of this organic oil with water containing sodium carbonate produces a soapy emulsion in addition to lime and magnesium precipitate.

Corrosion

Corrosion is evidenced by small pits or depressions and by large cup-shaped hollows on the metal surface, and occasionally by a considerable destruction of a large portion of the surface. Carbonic acid gas, occluded oxygen, sodium, calcium and magnesium chlorides are common causes of corrosion. Magnesium and calcium chlorides are very pernicious in that they produce free hydrochloride acid on hydrolysis. Corrosion is also found in boilers using a high percentage of condensate or distilled water.

Where pitting and corrosion occur under deposits of scale, the trouble is usually due either to the presence of free acid in the water or to the liberation of acid by the dissociation of magnesium compounds or other substances.

The corrosive effect of sulphuric acid in the boiler room follows an unending cycle of first dissolving iron and then precipitating it, liberating the acid which again immediately dissolves more metal. As a consequence of this condition a small amount of sulphuric acid within the boiler keeps up a constant attack on the metal and this corrosive action may occur with a boiler feed water in which no free acid is present when delivered to the boiler.

Pitting and corrosion, when found in equal intensity both above and below the water line, may be attributed to the presence of hydrochloric acid which is volatile at boiler temperatures. While hydrochloric acid is not found in feed water it may be formed in the boiler from the decomposition of the chlorides of calcium or magnesium.

Dissolved oxygen may cause pitting and corrosion at or above the water line. It is more apt to be found in boilers which are operated intermittently, than in boilers which are under a constant load.

Sources of Water Supply

Boiler feed water is obtained from any one of four principal sources, as follows:

1—Condensate
2—Bays or lakes of fresh water.
3—Flowing streams
4—Wells

There is a fifth source of supply, city water, which, while it originates in one of the four sources listed above, demands separate consideration because of the treatment this water undergoes to fit it for public use.

Condensate—Condensate is certainly the ideal form of feed, a fact nowhere better evidenced than in the design of our modern central stations. Every effort should be made in all plants without exception to see that not a pound of exhaust steam from auxiliaries, pumps, stoker engines, traps, etc., is allowed to go to waste.

Lakes and Bays—Lake water has the merit of uniformity, and when a practical method of purification has once been developed, a standard of practice can be set up and maintained year after year. Lake water is almost invariably alkaline seldom badly bi-carbonate, and in general presents no serious problem.

Flowing Streams—With rivers we have an individual problem as one stream is acid and the next alkaline. Moreover, the number of parts of impurities to the gallon varies not only from season to season, but daily and hourly. There is one redeeming feature, however, in that this variation in the quantity of impurities does not extend to the ratio of the impurities one with another. This means that in dealing with river water, we can count on the same relative percentages of impurities one with another at all times, and this greatly simplifies our problem.

Wells—Wells are seldom used for boiler feed when other sources are available. Generally speaking they contain a concentration of impurities, and while the water is almost uniform in its analysis, still the quantities of impurities to be disposed of are so great that adequate treatment is a real problem.

City Water—City supply, while pure enough for drinking purposes, is usually a dangerous proposition for boiler feed. It is very apt to contain chlorine, which presents a serious problem in itself. If it has been filtered, the organic matter has largely been removed, but the scale forming salts remain.

Specification for Ideal Water Purification Plant

The ideal boiler purification plant should measure up to the following specifications:

1—It should produce a water with which can be maintained an internal boiler condition of predetermined alkalinity, without by-carbonate, without scale formation, without corrosion and without foaming.

2—There should be no deposits in the feed lines and pumps and no undue wear on valves and moving parts.

3—There should be no bad effects from steam to prime movers, packing or lubrication, or to the product, if steam is used for industrial purposes.

4—It should involve a minimum of expert attention and should require only simple standard chemical elements, using standard reagents and standard indicators.

5—Fitters should not be required.

6—Its capacity should be unlimited and the cost low.

Overhauling and Adjusting in the Engine Room

This Article Describes the Valve Motion of the Marsh Pump—The Operation of the Valve—The Self-Governing Action—The Cushioning Valves—Maintenance and Repair

By "FITTER"

CONTINUING our articles on the various types of simplex pump valve, we come to that of the American Marsh pump made by the American Steam Pump Company, of Battle Creek, Mich. This is a somewhat more complicated type of valve than those shown so far. However, with the help of the cut, it can be made quite clear, and its ingenious design fully understood.

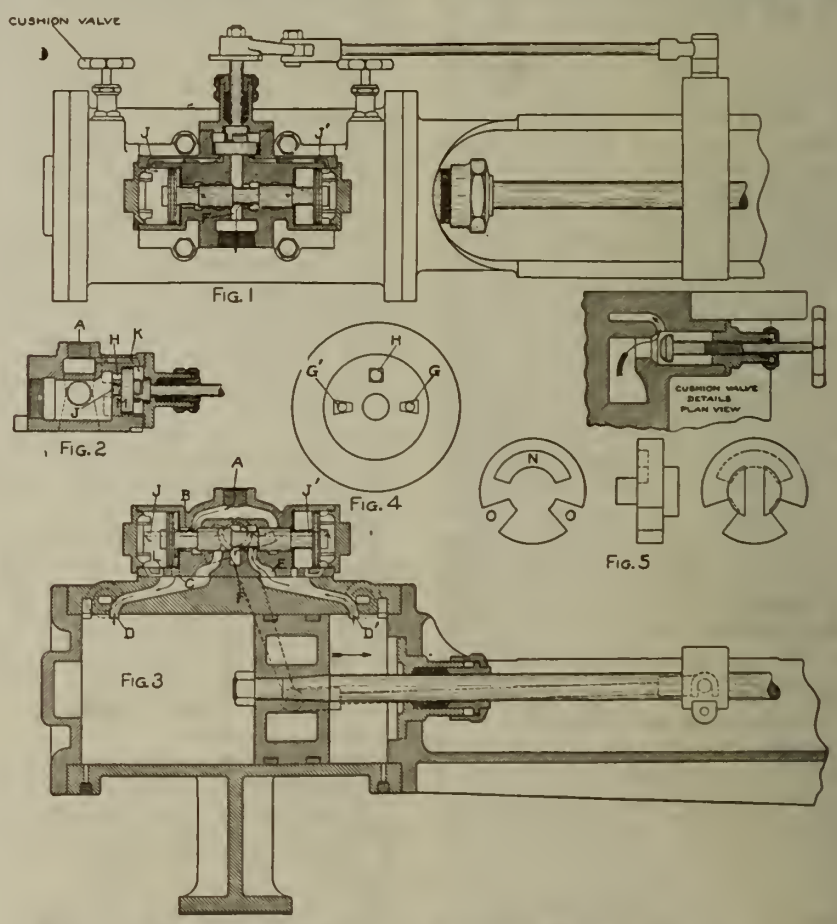
Looking at the cut, the lower view Fig. 3 shows a sectional elevation of the cylinder and steam chest, showing the main valve and steam ports. In the top view Fig. 1, is shown a plan view of the main and auxiliary valve, and the lever which operates the auxiliary valve from the pump rod crosshead is shown. The two valves one at either end of the cylinder, which are used for cushioning are also seen on this view. The intermediate views show details of the auxiliary valve and valve seat, and the cushion valve and its ports.

The Operation of the Valve

In the view shown in Fig. 3, the steam piston is on the outward or forward stroke, and steam is being admitted to the steam chest through the pipe A, through the throat passage B, and the passages C and D. On the exhaust side of the piston, the steam is passing out through the ports D, E and F to the exhaust cavity. The openings to these passages are controlled by the position of the steam valve and this is in turn controlled by the auxiliary valve. The separate halftone of the valve will show the arrangements of the ports more clearly than the small general view. Referring to Fig. 1 again, which is a plan view of the steam chest and auxiliary and main valves, the ports commencing to the main valve from the auxiliary can be seen marked J and J'. The valve lever is shown connected at the back of the auxiliary valve, where it fits into the slot shown in the right hand view of Fig. 5. Figure 4 is a view of the auxiliary valve seat, and it will be seen that the ports G and G' are in direct communication with the ports J and J'. The auxiliary valve front, back, and side views are shown in Fig. 5, and it will be seen by the front view that there are three ports in the valve. The two ports O and O correspond to the ports G and G', while the port N is made long enough to cover the ports G and H in one direction or G' and H' in the other. The action of the valve lever is to oscillate the auxiliary valve, alternately admitting steam to the back of the main valve through the port J and J' and exhausting it through the same ports. When the auxiliary valve is turned by the valve lever so that the port O covers the port G', then the port N will be covering the ports G and H, thus allowing the steam at that end of the chest to exhaust through the port J to F. The result will of course be to move the main valve over to the other side of the steam chest, reversing the movement of the piston. The auxiliary valve chamber is supplied with steam through the port K in Fig 2, and the pressure tends to keep the valve up to its seat.

Self Governing Action

It will be noticed that the area of the inner side of the main valve heads is smaller than the outside by the amount of the area of the body of the valve. This difference of area is used as a means to govern the motion of the piston. In the position of the valve in Fig. 3, the inside of the head is in communication with the entering steam through the passage B, and this would tend to move the valve over to the left, thus closing the port B to steam. To counteract this, steam is admitted from the cylinder to the back of the main valve, acting on the greater area, though with reduced pressure. This overcomes the tendency of the higher pressure steam on the lesser area, and the valve is thus kept in perfect balance. Suppose now the pump should lose its water, and tend to run away violently as pumps do. Having no resistance on the water end, the steam piston would advance very rapidly. This would of course reduce the steam pressure in the cylinder and therefore on the back of the main valve, while the admission pressure on the inner head would remain the same. The result would be that the high pressure steam on the small area would overcome the resistance of the lower pressure steam on the larger area, and the valve would move to the left, thus closing the port B and shutting off the steam. On the other hand, when the pump has a full head of water to pump against, the pressure on the piston approximates closer to that of the admission steam, and tends to move the main valve to the right and thus give a larger opening to port B. The same applies of course to both ends of the cylinder. This is a highly ingenious valve, very well designed.



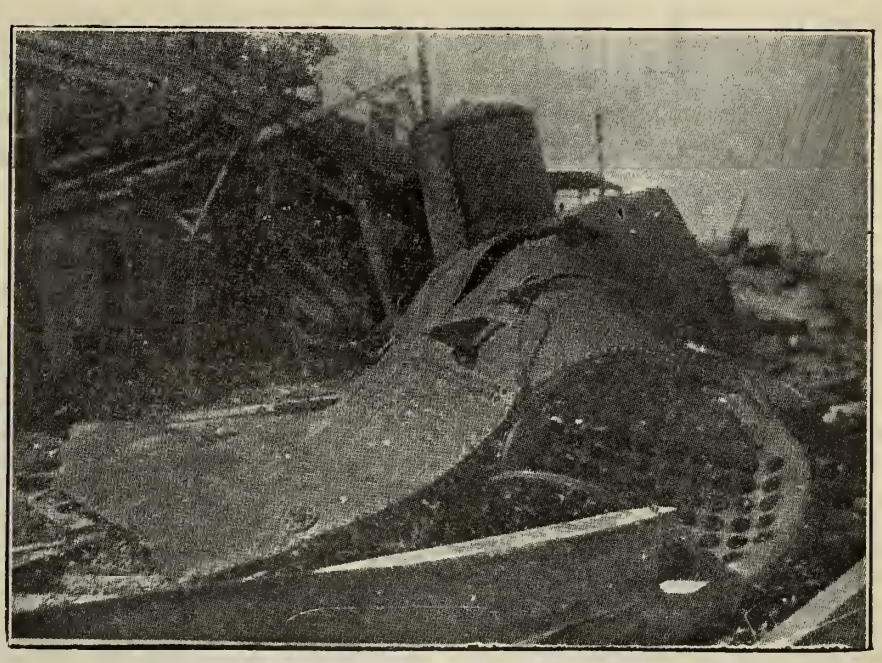
Details of Main and Auxiliary Valves

The Cushioning Valves

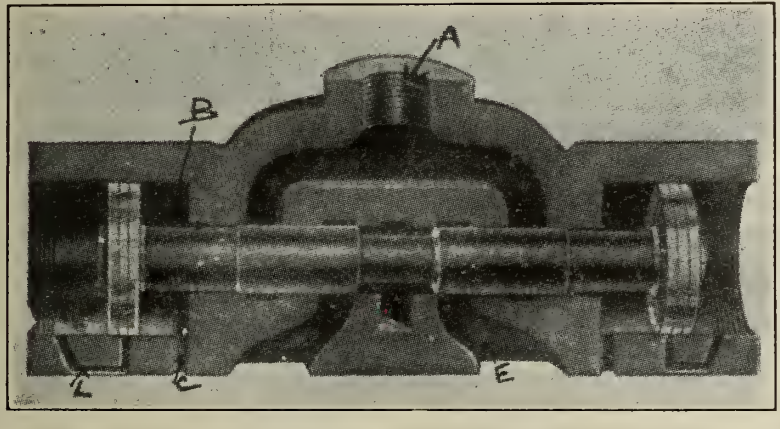
The plan view of the details of the cushion valve will explain its action without much help from the text. The small

port at the extreme end of the cylinder communicates with the main exhaust part, the cushioning valve being placed between them as shown. If the cushion valve is quite shut, then the steam in the cylinder will be trapped as soon as the piston covers the port D', and compression will start immediately. If the cushioning valve is left wide open then of course there will be no compression, and the piston will strike the cylinder end. The way to set these valves as recommended by the makers is to leave them open allowing the piston to strike the ends of the cylinder lightly, and then adjust them till quiet working is secured.

This valve also has the advantage of but few working parts, these being confined to the auxiliary and main valves inside the steam chest, and the auxiliary valve spindle with its lever and two swinging joints outside. The maintenance of this resolves itself into a matter of bushings and pins for the lever joints, while the auxiliary valve being of the



A VIEW OF THE RUINS.



ARRANGEMENT OF MAIN VALVE.

disc pattern, should wear to a perfect face all the time. The wear on the main valve, with ordinary care and lubrication, should be very slight, and its life indefinite. In case of necessity of replacement, it is a simple job, and when a machine shop is on the premises it would be very easy to take the valve chest and bore it turning up a spindle to fit. Of course, if within reasonable reach of the makers, spare parts could be secured in a short time, but allowing for the fact that this is not always possible, the above applies.

THE BOILER AFTER THE EXPLOSION

FATAL BOILER ACCIDENT

The accompanying illustrations show the damage effected by the explosion of a horizontal return tube boiler in the mill of the McKeithan Lumber Company, South Carolina, in April last.

The mill had been idle for some time and was about to resume operations, the boiler plant having been fired up for this purpose. About two hundred men were about to report for work, but shortly before they arrived, the boiler exploded with terrific violence. If the accident had occurred a little later the casualty list would have been much larger, but as it was, two men were killed. The mill itself was almost entirely destroyed, the damage being estimated at $30,000. The accident was reported and illustrated in the pages of the "Locomotive" to whom we are indebted for this account.

The boiler was built with two sheets, one upper and one lower, with two horizontal lap seams running the full length of the boiler. The explosion as is usual in this type of construction, was a result of a lap seam crack. Whereas a boiler subject to this type of defect is always treacherous, the long seam gives additional opportunity for an extremely violent explosion because the boiler may rip open from head to head. This is clearly shown in the illustration, and evidence of the fatal lap seam crack can also be seen.

The Lubrication of Air Compressors

Lubrication in General—Nature of Friction—Mineral Oils in General —Density, Viscosity, Flash Point—Physical Properties of Oils for Lubricating Air Compressors

By A. D. RISTEEN

THERE are many opinions on the subject of air-compressor lubrication. Only the internal lubrication of the air-compressor will be considered, and perhaps it may be well to begin by giving a little thought to lubrication in general.

Lubrication in General

Let us go back to fundamentals, and ask why we lubricate machinery.

In the first place, we desire to reduce friction. Needless friction involves the expenditure of a corresponding needless and therefore wasteful amount of mechanical energy. Furthermore, friction causes the rubbing parts to wear away, and that means overhauling and repairs. Finally, heat is developed where the friction occurs, and this is specially objectionable in an air compressor or any other mechanism that must be artificially cooled in any event, on account of the generation of heat from causes other than friction. We certainly do not want to develop avoidable additional heat in any place where we have to take special measures to remove the heat that is necessarily generated there.

Another reason why we need lubrication in the cylinder of a steam engine or an air compressor is, that it is important to seal the space around the piston, in order to prevent leakage under the piston rings or between them and the walls of the cylinder.

Nature of Friction.

We are told that friction is due to the interlocking of the little irregularities on the surfaces that are sliding or rubbing upon each other. Beyond all question there is considerable truth in this theory, but it certainly does not tell the whole story. When dealing with surfaces that are appreciably rough, we may be sure that there is a certain amount of interlocking of the projections, comparable in a small way with the interlocking that occurs between the teeth of a pair of gears. To reduce this interlocking, and the consequent resistance to motion, we make our sliding surfaces reasonably smooth,—reducing the projections until they are no longer of any practical importance; but even when the bearing surfaces appear to be absolutely smooth, we have not wholly eliminated friction—nor, after passing a certain stage, have we even reduced it in evident proportion to the increasing smoothness. A smooth bearing that is run without lubrication is likely to stick or "freeze," and although this action is attended by the development of heat, the temperature at which it occurs is usually far below the welding point.

We usually think of a lubricated shaft as floating on or in a film of oil, which is drawn inte the space between the shaft and its bearing partly by the rotation of the shaft and partly by capillary attraction. This conception doubtless corresponds with the facts in large measure, yet it cannot be altogether correct, because if it were the friction would be wholly fluid friction, and it would be practically independent of the nature of the lubricated surfaces.

The fact that flotation is not the whole story may be shown by a simple experiment described by W. B. Hardy ("Nature, December 30, 1920, page 569). To perform it we need a smooth, clean sheet of plate glass, and a glass weight with a similarly smooth, clean surface. The sheet of glass is placed in an inclined position, with the weight resting upon it near the upper end. By increasing the steepness of inclination of the plate, we presently reach an angle at which the weight will just slide down the plate freely. If we now wet the lower half of the plate and let the weight slide down as before, we find that it stops as soon as it comes to the wet part. Let us now repeat the experiment, using a glass weight as before, but substituting a polished sheet of ebonite for the plate of glass. If the steepness of the ebonite surface is adjusted so that the glass weight will not quite slide but is on the verge of doing so, we shall find that it slides down quite freely when the ebonite surface is wet with water. The water increases the friction in one case, therefore, and lessens it in the other; and this shows that the friction problem is quite complicated, if we try to go into it at all deeply, even when we confine our attention to the most elementary phases of it, and do not take account of such things as the deterioration of the lubricant through use, or the means by which it is to be effectively applied to the surfaces.

Mineral Oils in General

In specifying an oil for lubrication purposes, it is customary to indicate the chemical nature of the oil in a general way, and to specify (1) its density, (2) its flash point, and (3) its vicosity.

It is universally agreed, I am sure, that the oil used for lubricating air-compressor cylinders should be purely mineral, and we shall therefore take that much for granted.

Oils of this nature may be divided into two general classes which are known, respectively, as paraffin-base oils and asphaltic-base oils. The paraffin-base oils occur notably in the Pennsylvania region and the Appalachians, and the asphaltic-base oils are specially associated with the extreme south and west. The mid-continent oils may belong to either system, and some of them are mixtures of the two. Crude paraffin-base oils, upon distillation, leave solid residues consisting of hydrocarbors of the paraffin series; and the asphaltic-base oils, upon distillation, leave solid residues of an asphaltic or bituminous nature. I believe, however, that either group can furnish oils well adapted to thepurpose we have in mind.

Density.

The density of an oil is usually specified on the scale devised by Antoine Baumé—a French chemist who was born in 1728 and died in 1804. In accordance with his plan the density of a liquid is determined by immersing in it a float having a projecting stem which is graduated in accordance with a certain arbitrary plan. Two different methods of graduation are used, according as the liquid to be tested is lighter or heavier than water. In establishing his scale for oils and other liquids lighter than water, Baumé immersed the float in a solution containing 10 parts of common salt to 90 of water, and the point at which the liquid then stood, on the stem, was defined to be "zero." The instrument was then placed in distilled water, and the point on the stem that was level with the surface of the water was marked and defined to be "10 degrees." Between these marks the stem was divided into 10 equal spaces or "degrees," and the rest of the stem was graduated in degrees of this same length. It would be much better and simpler to state the specific gravity of the oil, rather than to use such an arbitrary scale; but inasmuch as the Baumé hydrometer is in general use by oil men, we shall have to abide by it for the present. Tables are given in many works of reference, to enable us to translate Baumé readings into specific gravities, or the converse.

Viscosity

Viscosity is the quality that makes molasses run slowly in January. In oiling watches and other fine machinery, the viscosity of the lubricant must be very low; but in dealing with heavy machinery it is necessary to use an oil with a considerable amount of viscosity so that the pressure to which the oil is subjected will not force it out of the bearings, nor wipe it off of the surface that is to be lubricated. For each particular lubrication problem, in fact, the viscosity should lie within certain appropriate limits, which will vary according to the nature of the conditions to be

*An address delivered by A. D. Risteen of The Travelers Insurance Co., before the Engineering Section of the National Council in Philadelphia.

met, and which must be ascertained by experience.

The viscosity of an oil falls off with increasing temperature, and often to a great extent. In choosing an oil for use in a hot place like the interior of the cylinder of a steam engine, or a gasoline engine, or an air compressor, we should therefore be sure that the oil we select will have a suitable viscosity at the temperature at which it is to be used; and this may mean that it is exceedingly thick at the ordinary room temperature.

In the United States, the viscosity of oils is determined mainly by means of an instrument devised for this purpose by G. M. Saybolt; though the United States Government has in the past made considerable use of a similar instrument designed by Englar, and extensively employed in Continental Europe. The main objection to the Saybolt apparatus has been, that until recently its construction and mode of use have not been sufficiently standardized. This has recently been remedied, in large measure, by the American Society for Testing Materials ("Proceedings," Vol. 19, 1919, Part I., p. 728) and the United States Bureau of Staudards ("Technologic Paper No. 112," 1919); and it is likely that the Saybolt universal viscosimeter will be the standard instrument in this country, hereafter, for the practical determination of oil viscosity. In using it, sixty cubic centimeters of the oil to be tested are allowed to flow into a receiver from a glass tube of specified shape and dimensions, and the number of seconds that are required is taken as the measure of the viscosity. Thus when we say that an oil has a viscosity of "140 S." (the S. standing for "Saybolt"), we mean that sixty cubic centimeters of the oil will flow out of the standard tube in 140 seconds. The measures so obtained are only relative, it is true, but they give a good means of comparing oils with one another, and that is all that is needed for most of the practical applications that we hace to make, in the arts. v

Flash Point

The flash point of an oil is the lowest temperature at which the oil gives off a vapor than can be ignited by means of a flame or an electric spark. The temperature at which actual ignition occurs without the application of flame or an electric spark is a totally different thing, and is called the "fire test" or "ignition point." It is important to remember this distinction in discussing air-compressor explosions; yet we often hear the "flash point" erroneously referred to as though it were the temperature at which an oil will burst into flame spontaneously. In the United States, flash points are determined by means of the so-called "open-cup" apparatus, in which the oil under examinatio nis gradually heated until the vapor from it can be ignited by a flame or spark—the temperature at which this first becomes possible being noted by a thermometer, and recorded as the flash point. To obtain uniform and consistent results in this work, skill and experience are required.

Physical Properties of Oils for Lubricating Air Compressors.

In lubricating the cylinder of an air compressor, we must use an oil that is viscous enough to resist the tendency of the piston to wipe it off and leave the metal surface dry; but the viscosity should not be great enough to offer any considerable opposition to the motion f the piston. We must remember, in other words, that lubrication is intended to diminish friction, as well as to seal the piston so that air cannot leak around it. The errors that are made in selecting oils for lubricating air-compressor cylinders pobably tend toward a viscosity that is too high instead of too low. The average viscosity corresponding with good practice ranges from 230 to 315 seconds on the Saybolt scale for paraffin-base oils, and from 275 to 325 for asphaltic-base oils. The minimum limits for viscosity in good practice are given as 120 S. for paraffin-base oils and 175 S. for asphaltic-base oils.

The average density for good practice is given as 25° to 30° Baumé for paraffin-base oils, with a minimum of 32° and a maximum of 25°; and as 19.8° to 21° Baumé for asphaltic-base oils, with a minimum of 22° and a maximum of 19.5°. (Higher readings correspond, of course, to lighter oils.)

In connection with the flash-point tests (as made by the open-cup apparatus), 400° to 425° Fahr. are recommended as good average practice for paraffin-base oils, and 315° to 335° Fahr. for asphaltic-base oils—the fire test being higher than the flash point by about 50° in the paraffin-base oils, and by from 55° to 65° in the asphaltic-base oils.

Explosions of External Origin

In considering the relation of lubrication to air-compressor explosions, we may note that these accidents are sometimes due to causes external to the air end of the machine. As an example of an explosion initiated by an external cause, yet having a certain bearing upon the lubrication problem, I may cite a case in which the steam pipe running to the compressor failed, doing considerable damage in a small way to the machine, and incidentally causing the rupture of the air pipe and liberating the contents of the receiver. Shortly after this occurred there was a violent secondary explosion, which blew out the whole side of the building. It is believed that there was considerable oil in the bottom of the receiver, and that the escaping air blew this oil out into the room in the form of a fine spray. A battery of boilers was located in the same room, and we may reasonably suppose that the spray took fire at one of the furnaces. A gallon or two of oil disseminated through the air in the form of mist could easily give rise to a violent explosion, when brought in contact with flame or with a bed of white-hot coals.

It is bad practice to allow considerable quantities of oil to accumulate in a receiver tank, or in any other part of the air system. Every receiver tank should be provided with a drain pipe having a diameter of at least half an inch, and preferably three-quarters of an inch; and these drains should be opened frequently and regularly, to remove any oil or water that may collect in the receivers. Appropriate means should also be provided for draining other parts where oil may accumulate.

We are mainly interested, on this occasion, however, in accidents consisting in the explosion of something inside the compressor or its piping or other connections, or which are initiated by such internal explosions; and in considering these we naturally ask ourselves, to begin with, what there is inside of the compressor or its connections that can explode.

The Oil-Vapor Theory of Explosions

A good many persons who have speculated on air-compressor explosions from internal causes have attributed them to the ignition of oil vapor. The air in the compressor cylinder has a rather high temperature during a part of each cycle, in consequence of the heat developed by the compression. In an ordinary air compressor with tight valves, the theoretical limit of temperature might be somewhere about 600° or 700° Fahr., if the compression took place adiabatically —that is, without any loss of heat. In the actual machine, however, there is a considerable cooling action largely on account of the water jackets; and when the compression is effected in two or more stages, there is further cooling in the intercolors that are(or should be) provided between each cylinder and the one next following. Taking these things into account, the maximum temperature occurring in any given cylinder should not exceed something like 400° Fahr. It would be useless to make a more definite estimate than this, because the figure will naturally vary with different machines.

It has been maintained that lubricating oil is likely to give off an inflammable vapor at the temperatures indicated; and this vapor, when mixed with the air in the compressor, has been supposed to be capable of exploding and producing the observed effects. Let us examine this theory a little more critically. In the first place, some of its opponents have confidently stated that explosions occur in connection with high flash-point oil even oftener than they do in connection with those having low flash points. If this could be satisfactorily established, it would practically sound the knell of the oil-vapor theory; but as I cannot substantiate the statement, I shall not base any conclusions upon it.

Most of the oil that is present in a compressor cylinder is lodged upon the walls of the cylinder, and owing to the proximity of the water in the cooling jackets, these walls do not have a temperature anywhere near as high as the air in the middle of the cylinder. Under good operating conditions and with well designed apparatus, the inner surface of the cylinder wall is probably not much

more than 50° Fahr. hotter than the maximum temperature of the jacket water. If this is so, it follows that the oil that is adhering to the cylinder is not giving off any significant amount of inflammable vapor, because the greater part of it is adhering to the comparatively cool metal. Some of the oil will be lodged on the face of the piston and this may be not enough to give off a certain amount of inflammable vapor, if the flash point of the oil is lower than the maximum temperature of the air in the cylinder. It is important to note however, that under normal working conditions the air in the cylinder is comparatively cool during the greater part of every cycle—the high temperature being attained only toward the end of the compression stroke. Hence the total evaporation of oil from the faces of the piston will be far smaller than the advocates of the oil vapor theory have probably assumed.

Furthermore, any oil vapor that is present in the cylinder is swept out with the air every time the cylinder discharges into the receiver; and in the normal working of the machine the vapor that is formed per cycle cannot, on the average, exceed that which could be formed from the amount of oil that is admitted per cycle. With proper lubrication this amount will be so small that we cannot conceive it to be capable of doing the least harm. Certainly it could not produce a violent explosion.

Oil spray in the cylinder or connections is sometimes suggested as a thinkable source of explosive action. It is hard to understand how spray could be formed from oil that has once adhered to the metal walls, except in consequence of the rupture of some part of the apparatus as already described; and in connection with the oil that is introduced into the compressor with the inflowing air, and which has not yet attached itself to the metal parts, the arguments already reviewed in connection with oil vapor appear to be conclusive. Namely, any spray of this kind that does not immediately lodge upon the walls is swept out into the receiver with the next discharge from the compressor; and moreover, the amount of oil spray, under any half-way reasonable conditions of operation, would be so small that any explosion that it might produce would not even be noticeable.

Dust and "Carbon"

We come, now, to the consideration of such combustible solid matter as may be present in the cylinder or its connections; and here we are encountering a far more serious item. The free solid matter that is found in the cylinders, piping, and receivers of air compressors is of two general kinds. First, it contains whatever may have been introduced into the air compressor in solid form—for example, dust drawn in through the intake. The dust held in suspension by the air that is taken into the compressor usually contains more or less mineral matter, which is likely to be either sandy or clay-like. Such matter is incombustible, and probably would not be directly harmful except as it may increase the friction and the wear. But the incoming air may also contain combustible material, and this must be reckoned with. The combustible matter may be of an organic nature, or it may consist largely of particles of carbon. This last condition is most likely to prevail when the intake of the compressor is located near a coal pile, or where it can take in more or less smoke from a chimney or stack. To prevent accumulations of this kind, it is highly important to draw in the air from a place as free from dust as possible. It would be wise to filter the air through dust-proof and smoke-proof screens, before allowing it to enter the compressor. This is not always practicable however.

"Carbonization" of the Oil.

The other source of solid matter in the cylinder or receiver or connections is the so-called "carbonization" of the oil itself. We speak of solid deposits of this nature as "carbon"; but although they contain free carbon, they consist largely of oil in various stages of disintegration, and of compounds formed from the oil under the influence of heat and the oxygen of the air. (For a good account of the carbonizing of lubricating oils, covering the nature of the deposit and the theory of its formation, consult Circular No. 99 of the Bureau of Standards, 1920.) Carbonization is due in large measure to the use of improper oil, or of an excessive amount of oil. The oil should have such a composition that it is reasonably stable, at the temperatures that are likely to occur in the compressor or its connections; and this means, among other things, that it should not contain any animal or vegetable constituents, but should be purely mineral. Any oil will undergo a certain amount of decomposition, however, under the conditins to which it is exposed in air-compression apparatus. Slow oxidation is favored by the fact that the oil is spread out in a thin layer and exposed to heated air. Moreover, at the temperatures that prevail in the apparatus the oil is likely to "crack" to some extent. That is, it is likely to break down, slowly, with the formation of somewhat lighter oils, and the simultaneous liberation of a certain amount of free carbon. No oil that is worth even momentary consideration contains, in its original state, any free carbon; and the percentage of carbon present in the oil (in combination with hydrogen) is no criterion whatsoever of the likelihood of the oil to deposit carbon. The carbon deposits thrown down by paraffin-base oils are said to be hard, gritty, and specially adhesive, while those that are derived from asphaltic-base oils are described as fluffy and easily removable. However that may be, it is certain that any oil that gives a considerable deposit of so-called carbon is objectionable in connection with air-compressor lubrication, whatever the nature of the deposit may be. For example, the "carbon" may interfere with the valves of the compressor, and prevent them from closing properly.

Now, as to the amount of oil that should be used. As a rule, air compressors are over-lubricated. The walls of compressor cylinders are dry, and oil sticks to them far better than it does to the cylinder of a steam engine. Therefore, it is not necessary to use anything like so much oil in the air compressor. Roughly speaking, the amount used in a compressor cylinder should never exceed one-quarter the amount that would be used in a steam cylinder of equal size, and a smaller quantity than this is usually preferable. Some authorities state that it is advisable to use only one-tenth the quantity that would be required in a steam cylinder of like capacity. It is not practicable to make a hard-and-fast rule covering this point, because it is necessary to allow considerable latitude on account of variations in the oil, and in the working conditions. The best plan is, to remove a valve from time to time, and examine the condition of the cylinder surface. If it is covered with a thin film of oil, the lubrication is at all events sufficient; but if it is dry, more oil should be supplied. The quantity of oil used should be as small as is consistent with the maintenance of the oil film.

Care of the Cooling Jackets

In conclusion, I wish to make one suggestion which, although it is not directly connected with lubrication, is nevertheless quite important and may have a good deal to do with the safety of the machine. I refer to the proper care of the cooling jackets. If the water that is circulated through these jackets contains much scale-forming matter, a solid stony coating is likely to form, in the course of time, on the cylinder-wall of the jacket, and this will naturally diminish the cooling effect of the jacket, and allow the cylinder wall to become needlessly hot. Heavy accumulations of a muddy or sandy nature are also likely to form in the water jackets, when the water contains considerable quantities of sediment, and in a bad case of this kind the jacket-space may be entirely filled up, except for a small channel extending through the deposit from inlet to outlet. Of course a jacket that is in this condition is useless as a cooling device.

The jackets should be watched for evidence of deposits of sediment or scale, and whenever anything of this kind is found, it should be removed by appropriate means. It may be possible to wash out the mud by using a strong stream of water,—stirring up the deposit, if necessary, by means of a flexible rod or something of that nature. When a stony deposit of scale is found, it should be removed by filling the jacket with a hot solution of caustic soda or some other suitable substance; and if there is much trouble of this kind the water should be purified before admitting it to the jacket, or the source of supply should be changed. Where trouble is experienced from sediment, the water should either be filtered before use, or be allowed to stand in large settling tanks until it has become clear.

In any event the supply of water

should be abundant, and the man in charge should know, with the utmost positiveness, that there is a free flow through each jacket. The best way to make sure of this is by having the discharge from the jacket visible, and locating in a conspicuous place, so that any significant lessening in the quantity of escaping water will be noticed at once. This precaution is a wise one, in fact, in connection with any apparatus in which a circulation of cooling water is important.

Ignition of the Carbon.

It is well known that these carbon deposits take fire, at times, when the conditions are favorable; and this can hardly be due to the air in the compressor attaining a temperature high enough to ignite pure carbon, especially when the carbon is in compact form. Bearing in mind the fact that the deposits seldom or never consist of pure carbon, but contain considerable quantities of decomposed oil and other substances, we can get a glimpse of certain interesting chemical possibilities which I will briefly outline.

It is not unlikely that the free carbon that is present in the deposits occasionally acts as a catalyzer, in promoting the rapid oxidation of the oily matter with which it is associated. Catalysis plays an important part in modern chemical manufacturing, and we are enabled, by means of it, to bring about many chemical reactions that will not occur unless a suitable catalytic agent is present. Charcoal and coke are among the substances used, in this way, to promote certain chemical actions; and perhaps it is not unreasonable to assume that the carbon in a compressor or its connections may sometimes induce rapid oxidation of the oily matter. It is known too, that some of the products that would be formed in this way are themselves capable of acting as catalyzers, so that they might accelerate the action when it had once become well started. Fine metallic particles, worn off from the cylinder or the piston, are sometimes present in the deposits; and iron oxide often occurs to a significant extent—both being active catalyzers under certain conditions.

The heat generated by the beginnings of the oxidation would facilitate further action, and so the thing would go on, until presently we might have a glowing or burning mass. This in itself might precipitate an explosion, by heating the metal walls so that they could no longer withstand the normal air pressure to which they are subject. Furthermore, the carbon deposit, if it happens to be of a light and fluffy nature, may be disturbed so that we have what is in effect a dust explosion, the finely divided carbon playing the part of the dust and the ignition taking place in consequence of the catalytic firing of the oily matter in the way I have described; and even if the carbon deposit were originally compact and hard, it might take on a loose, sooty character as soon as the oily matter combined with it had burned away. Somebody has calculated the amount of carbon dust that would be required to give an explosion comparable in violence with those that have been recorded, and he finds that if the carbon that is ignited in the form of dust were sufficient in amount to fill half a cubic inch when compressed into compact form, we should have enough explosive material to explain any accident of this type that might be cited. I would not like to say, however, that it is the carbon only that explodes. What happens after the trouble has started, is more than I can guess.

Hard carbon deposits often prevent the valves of a compressor from closing properly, and this is likely to cause serious overheating. The piston, in making its return stroke to fill the cylinder with a fresh charge of air, will be followed by a certain amount of the compressed and therefore heated air, flowing back through the leaky valves from the receiver and its connections. Under these circumstances, the contents of the cylinder are already, and before the compression begins, at a temperature considerably higher than that of the surrounding atmosphere; and this means that when the next compression stroke is completed, the temperature in the cylinder may be a good deal higher than it would be if the valves were tight. The increase in temperature produced in this way, and also by the friction of the air in churning back and forth through the restricted valve opening, naturally accelerates any tendency toward the production of fire and is, therefore, a serious matter.

Removal of Carbon and Oil Deposits.

Every effort should be made to prevent the accumulation of "carbon" deposits anywhere about the compression apparatus, and such matter as may be deposited in spite of all reasonable precautions in the way of selecting the oil and feeding it to the cylinder should be cleaned away, frequently and regularly. A good deal can be accomplished in the way of cleaning the compression apparatus by discontinuing the oil from time to time and feeding soapy water into the cylinder for two or three hours—say once a week. This often helps marvelously to clean out carbon deposits and deposits of gummy oil. The soap solution may be made up of one pound of soft soap to seven or eight quarts of water, and it is advisable to feed it into the cylinders at a rate something like ten times as great as the rate at which the oil is ordinarily supplied. The frequency with which this treatment should be given depends upon the experience that has been had with the particular air compressor under consideration. Some authorities recommend the introduction of a solution of lye into the pipe between the cylinder and the receiver, every month or two. The lye solution may be made up by using one pound of lye to eight or ten quarts of water, and it may be delivered into the air discharge pipe by means of a sight-feed lubricator at the rate of 60 to 70 drops per minute. After using the lye or the soap solution, the receiver should be blown off, and oil should again be used in the cylinder for a time, before stopping the compressor. Otherwise rusting is likely to occur.

When hard carbon deposits form, which are not removable by the treatment here suggested, they should be cleaned out by whatever means may suggest itself as most effective. For instance, the air valves should be removed whenever necessary and cleaned by mechanical means. No kerosene or other inflammable solvent should be introduced with the air, however. This practice, which is far from unknown, is exceedingly dangerous.

The Link Belt Company of Chicago have recently published a new book on Belt conveyors, known as book No. 215, dealing with Uniroll and Multiroll idlers recommended by the company for their equipment. The book also contains useful information in the shape of correct methods of figuring on belt conveyors and their capacity. Price lists are included which make it possible for the customer to figure up the whole cost of a proposed installation, or any portion of it. There are also suggestions as to the right type of equipment for different purposes, and a number of illustrations of typical installations are included.

The Canadian Link Belt Co., of Toronto and Montreal have issued a new steel data book No. 475. In this book is presented the heavier rugged steel chains used for Power Transmission, and it also includes elevating and conveying chains.

The U.C.C. Convention

THE Convention of the Universal Craftsmen just concluded at Toronto has been a notable event. A full report will be published in the next issue of the Power House, but in the meantime we feel that there are some things to be said about it that cannot wait.

The convention was the first that the Universal Craftsmen's Council of Engineers has ever held in Canada, though judging by the feeling of the delegates it will be by no means the last. It was the means of bringing to the city of Toronto upwards of two hundred operating engineers from all parts of the United States. These men, all of them occupying positions of responsibility and trust, and therefore with a certain influence in their respective communities, were practically all visiting Canada for the first time. Many of them before coming had some of the peculiar ideas of Canada and British Institutions that prevail in the inland cities of the United States. They came to Toronto, met engineers who could talk to them on as high a plane professionally as their own, saw an exhibit of engineering appliances that would be hard to equal in any exhibition they have ever attended, and were given excellent opportunities to see the business and social side of an essentially Canadian and British city.

It is a good thing for stationary engineering, and for Canadian stationary engineers in general, whether members of the craft or not, that a society so strongly representative should choose a Canadian city for their convention. A lot of people who had but a vague idea of what stationary engineers were have seen the well dressed and prosperous looking delegates attending the King Edward this week and have received a new conception of the importance of the stationary engineers in their daily life. Hundreds of people not directly interested in engineering have been tempted to look in and see the exhibition and have gone away with food for thought.

The local gentlemen who were responsible for the convention are to be congratulated for what they have done, not only for their own craft, but for stationary engineers and for the City of Toronto. With an example like this in front of them, we should like to see the old society, the C.A.S.E. many of whose members are also members of the U.C.C. spurred to greater efforts, for their own good and the general good of all engineers.

A Vision Worth While

THE WORLD is used to turning to the United States for stupendous undertakings, and not in vain, for while they do not always get the best, yet they usually have the biggest of everything. In another part of this issue will be found an account of the mammoth bridge which is being erected across the River Hudson, to form a great artery of commerce between the states of New York and New Jersey. The bridge like other bridges over the Hudson and East Rivers will be of the suspended type. It would no doubt interest greatly some of the ancient bridge builders of the far east, who in the dawn of the world swung their gossamer like structures on fibre cables over the gorges of the Himalayas, for they would see a structure, surpassing in dimensions anything that their wildest vision could have conjured up, and yet based on the principle that they themselves had used.

We say surpassing anything their vision could conjure, but it is by virtue of that very vision that all these modern wonders have been made a possibility. The bridge builder, challenged by the necessity of the times, and aided by the scientist who with infinite patience pursued the jealously guarded secrets of nature, saw in his mind's eye something larger than had ever been attempted, and with confidence in his ability and the material he had to work with, proceeded to make his vision a material fact. So from the crazy fibre bridge swinging above the abyss, and capable of supporting but one person at a time, we have come to the bridge that can carry foot passengers, wheeled vehicles, street cars, and railway trains with perfect safety. Each great bridge as it has been projected, has been a source of wonder to its generation. The Tay Bridge, the Forth Bridge, the first Brooklyn Bridge, and latterly the Quebec Bridge with its tragic history, have all caused those of little faith and less vision to remark "It can't be done."

Science , the handmaiden of industry, goes quietly on with her appointed task, and makes available better and better materials, which give added strength with less weight, and make it possible for the builder to plan bigger and bigger things . It is all a matter of vision. The scientist, who projects his mind into the abstract; the engineer who takes the result of the scientist's researches and applies them to practical use, and the capitalist, who from his faith in the engineer and scientist, gathers together the gold to make these visions possible, knowing well that though he stands for great reward, he may well stand to lose all. So science, industry, and capital go forward hand in hand, linking up town and country, state and nation till the day will come when all the world will be joined up with such arteries that the farthest points apart will be reckoned not in weeks, or days, but in hours.

Steel Belting As a Means of Transmission

Material Used on Such Belts Is a Carefully Hardened Charcoal Steel—Process of Preparation a Secret—Claims Made for This Belting—Safeguards—Stories of Installations

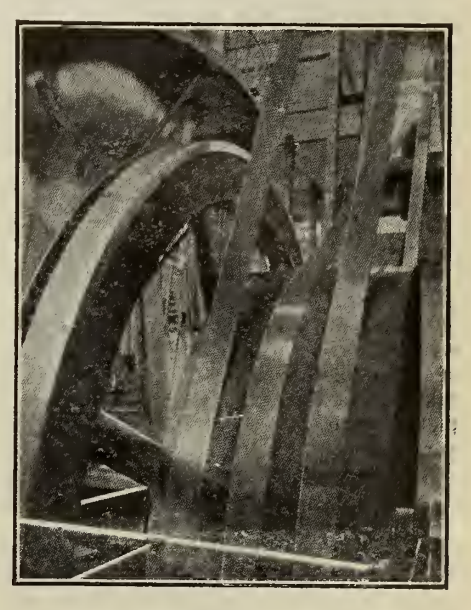
THE LOSS in power in transmission from the engine, whether steam or electrical, to the point of application is a difficulty which has always exercised the minds of engineers wherever mechanical power is used. Experimental attempts were made in employing driving belts of metal, but, after a short period of use they invariably broke when subjected to any considerable increase in load. Persistent failure also attached itself to the various connections used in joining the ends of the bands together. Subsequent experiments showed that these unsatisfactory results were attributable mainly to mistaken conceptions as to the conditions under which steel bands should be used. In previous experiments it was found that consideration was not given to the fact that the metal belt employed is subjected to a flexure constantly varying from zero to a maximum, and that to ensure durability with such a demand it was not sufficient for the belts to be calculated in the usual manner. The error consisted in not regarding the result of philosophical researches first undertaken by Wohler, according to which a tension constantly varying from zero value to a maximum and frequently applied to a body causes self destruction if the maximum tension is not confined to half the breaking stress of the material.

The present system is therefore based on the knowledge that a fracture of the belt even with a constantly varying demand on its flexibility can be avoided with certainty if the maximum demand likely to occur is kept so low that it does not attain half the value of the limit of fracture. Exhaustive series of trials have been carried out in England. According to the present method the breaking of belts is avoided, and the durability made unlimited by the thickness.

It was found that owing to the high modulus of elasticity of steel that it was very necessary to determine the length of a driving belt with considerable accuracy; a short extension compelled by cutting the belt too short in the first instance set up very serious stresses. To accomplish this purpose an ingenious device has been invented for determining the necessary length for the purpose of obtaining a truly correct working tension.

In the patented joint clamping plates are shaped to suit the pulley profile, stresses at the joint are distributed evenly over the whole width, and one of the most prolific causes of fracture in the early installations is thus avoided.

The material used is a carefully hardened charcoal steel, prepared by a secret process, rough rolled at a red heat, and then brought to 0.2 to 0.9 mm. thickness and 12 to 200 m.m. in width by cold working. The tensile strength of the finished material is about 95 tons to the square inch. The edges are rounded and finely finished, so enabling the belt to

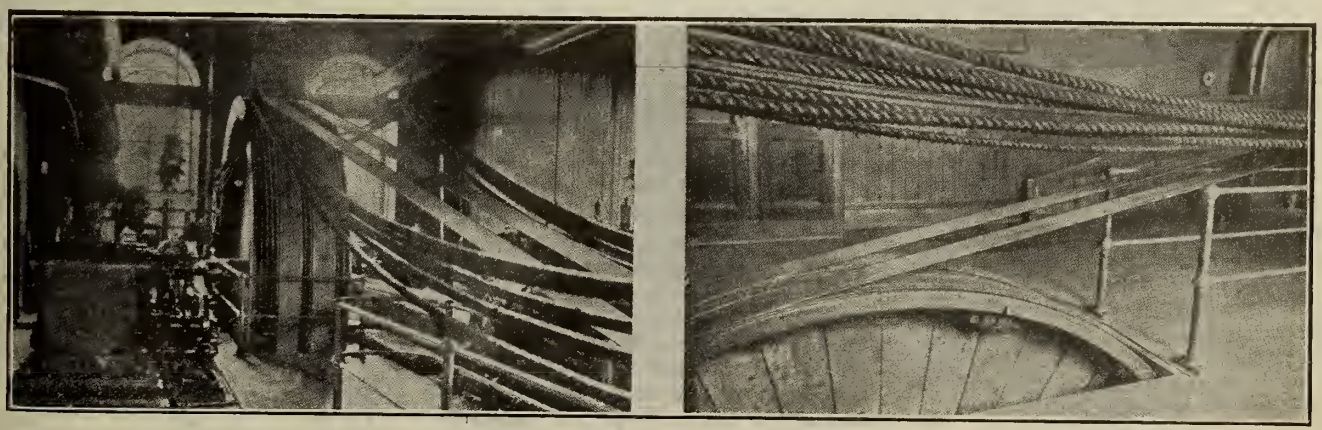


ANOTHER COMPACT STEEL BELT DRIVE.

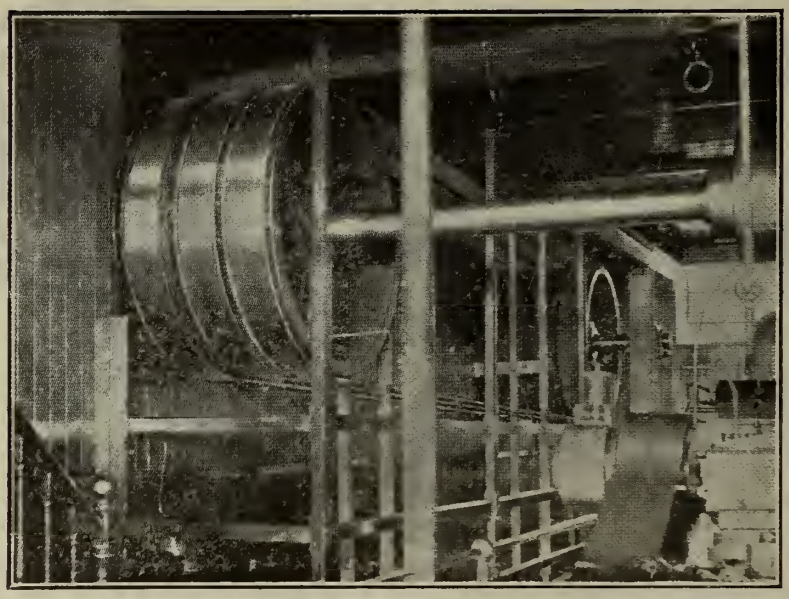
be safely handled even when running at high velocity. The elasticity remains unimpaired with use.

Friction Covering on Pulleys

So that metal does not run to metal



A 450 H.P. DRIVE. SHAFT CENTERS ARE 40 FT. 3 IN. PULLEY DIAMETERS 15 FT. 2 IN., AND 12 FT. 7½ IN. TWO 8 IN. STEEL BELTS REPLACED ELEVEN 1¾ IN. ROPES. THE SPEED RANGES FROM 70 TO 90 R.P.M. THIS DRIVE HAS BEEN IN USE SINCE 1915.



IN THIS CASE THREE 8 IN. STEEL BELTS REPLACED FOURTEEN 1¾ IN. ROPES. THE PULLEYS ARE 5 FT. 6 IN. EACH, AND THE SHAFT CENTERS 20 FT. 8½ IN. THE VELOCITY IS 2,400 FT. PER MINUTE, AND THE H.P. 310. THE BELTS RUN AT 142 R. P. M. THE DRIVE HAS BEEN IN USE SINCE 1915.

and to prevent any possible slip, a friction coating consisting of a layer of canvas, to which is glued fine sheets of cork is placed over the pulley rim, and to avoid stripping under variable load the pulley rim is first serrated by a rough file or chisel nuts. A special cement is available for use in very damp situations.

It is claimed that steel belts have replaced cotton rope drives in a number of cases and that the simplicity of the conversion is such that the conversion of a complete rope race can be undertaken on a Saturday noon and be completed with the steel belts ready for running the following Monday morning. The conversion is said to usually increase the horse power available at the driven shaft by 7 to 25 per cent., this being the result of a number of tests in actual installations. Where space is cramped and drives are running to various floors, steel driving belts are said to be very adaptable.

The requirements necessary to the successful employment of steel belt transmission are simple, but nevertheless important, and given suitable conditions, the results are definite and certain. When it is understood that steel belts must run perfectly true on to the pulleys the tension to remain exactly as when fitted, the conditions demanded will be easily comprehended. The shafts, bearings and fixings must be of a solid construction, strong enough to transmit the maximum load demanded. The shafts must also be parallel, and the pulleys running true and without vibration.

It should be clearly understood that the steel belt is only a part of what actually is a highly scientific system of power transmission. As already explained, the process of preparing the steel and the mounting of the belts is carried out on highly scientific lines.

Safeguards

With ordinary care steel belts are perfectly safe, as in case of fracture the belts will not fly, but fall between the shafts. The edges are rounded and can be handled whilst running. In every country where used they are placed under precisely the same laws and regulations as applied to ropes or leather belts.

Here are a few claims made by the makers of the type of belt we have been describing:

An efficiency in power delivery of 99-99½ per cent. Great steadiness; a necessity for electrical machinery, textile purposes, paper mills, etc. A perpendicular drive is no disadvantage for steel belt driving.

Absence of stretching — a steel belt does not stretch by use, as has been seen by eight years' experience. Even running, free from slip. As there is no actual measurable slip, it follows that transmission by steel belts is uniform and invariable.

Great power under present conditions. —In cases where the pulleys are limited in size it is often possible to get an increased power transmitted by the use of steel belts without any re-arrangement.

Cool bearings.—Owing to the exact calculations of the necessary tension for each particular drive, together with the great reduction in the weight of steel belt. Cleanliness.—No messy dressings are required.

Unwearability. — Steel driving belts have now been in operation for eight years, and tests made of the belts first fitted show no signs of deterioration whatever. It seems evident therefore that the life of the steel belt is unlimited.

Breakages

Where the conditions are in accordance with the requirements, it is only in very isolated instances in which a fracture occurs. These instances are invariably due to a flaw in the material itself, and will show within the first eight weeks of running; by this is meant that if a steel belt runs for eight weeks it is a practical certainty that it is free from flaw and will run indefinitely. To cover any serious stoppage caused by a faulty belt, the manufacturers will, if requested, supply with every drive a duplicate or reserve belt, measured and ready for immediate fitting.

Steel belts vary in width from 2½ in. to 10 in., and thickness 0.4 m. m. to 1.0 m. m.

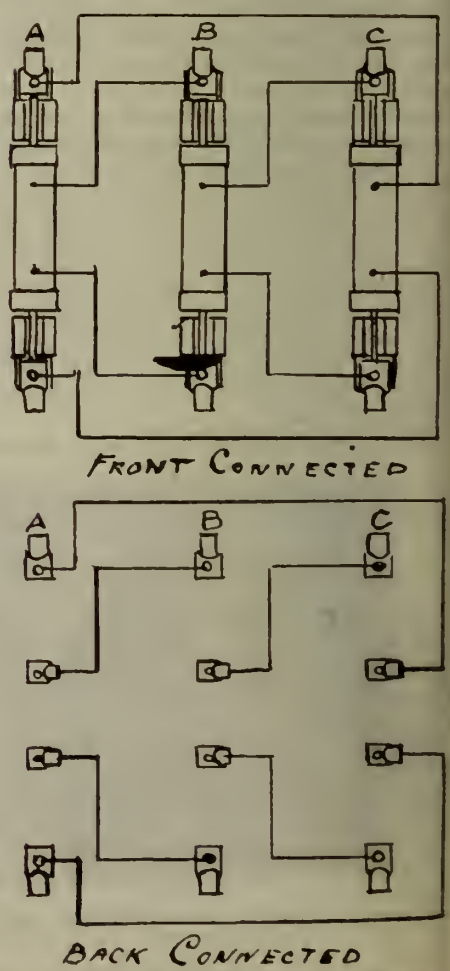
Several steel belt drives are performing good service in England where there are over 50,000 H.P. varying from 90 to over 800 H.P. drives in successful operation, some of these steel belt drives having been in operation over eight years. As steel belts may be applied in multiples there is no limit to the possible power to be transmitted.

Jones & Glassco, Engineers, St. Nicholas Bldg, Montreal, are the sole Canadian agents for this belting.

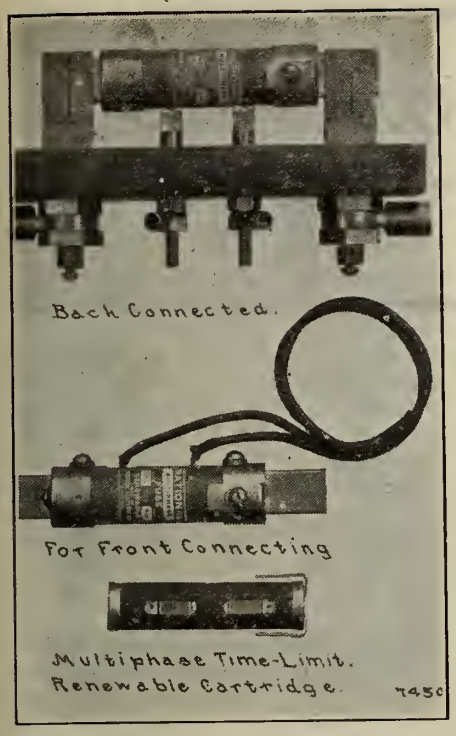
NATIONAL MULTIPHASE RENEWABLE FUSE

The Federal Electric Company of Chicago have developed with basic patent protection a low voltage auxiliary coil which is embodied in the renewal cartridge of National Renewable Fuses, and as the Cartridge can go into the case in but one position, it easily makes the auxiliary connection with the fuse case itself. Leads are then brought out for connecting the inter-phase circuit in either delta or "Y" connection and is made with either wire connections attached to the case for front connecting, or auxiliary knife-blade connections are attached for back connecting on panels, switchboards, etc.

National Multiphase Renewable Fuse, as the new device is known, serves two pur-



CONNECTIONS OF MULTI-PHASE FUSE.



VIEW OF CARTRIDGE.

poses. First, as a fuse it is so constructed that it withstands the high starting current of motors, yet protects the running load within the limits prescribed by the Underwriters' Laboratories, Inc. It is powder-packed, which is the best known fuse practice. It has the metallic "tell-tale" indicator which shows in plain view upon the outside of the fuse the rated amperage of the element with which the fuse is loaded. As the fuse is made for operation on Multiphase circuit, it acts as a circuit breaker, that is, when one fuse blows, the auxiliary device in the National Multiphase Renewable Fuse makes one of the other elements in one of the fuses blow, thereby breaking the circuit entirely and eliminating the possibility of the motor running as a single phase motor. This is really a time limit fuse and is absolutely fool-proof

The two greatest causes of motor interruption, occasioning great delays, loss in production, and costly rewinding of motors, are the overloading of fuses by placing two or more elements of too great a capacity in the fuse case and the running of motors as single phase.

WATER POWER RESOURCES

(Continued From Page 25)

the six month flow maximum power. Applying this, the figures quoted above therefore indicate that the at present recorded water power resources of the Dominion will permit of a turbine installation of 41,700,000 h. p. In other words the present turbine installation represents only 5. 9. per cent of the present recorded water power resources.

The figures listed in Columns 2 and 3 in the above table represent 24-hr. power and are based upon rapids, falls and power sites of which the actual existent drop or the head possible of concentration, is definitely known or at least well established. Innumerable rapids and falls of greater or lesser power capacity are scattered on rivers and streams from coast to coast which are not as yet recorded and which will only become available for tabulation as more detailed survey work is undertaken and completed. This is particularly true in the more unexplored northern districts. Nor is any consideration given to the power concentrations which are feasible on rivers and streams of gradual gradient where heads may be created by the construction of power dams, excepting only at such points as definate studies have been carried out and the results made matters of record.

The figures in Column 4 represent the actual water wheels installed throughout the Dominion. These figures should not be placed in direct comparison with the available power figures in Columns 2 and 3 for the purpose of deducting therefrom the percentage of the available water power resources developed to date. The actual water wheel installation throughout the Dominion averages 30 per cent greater than corresponding maximum available power figures calculated as in column 3. The figures quoted above therefore indicate that the at present recorded water power resources of the Dominion will permit of a turbine installation of 41,700,000 horse power. In other words, the present turbine installaion represens only 5.9 per cent of the present recorded water power resources.

The above figures may be said to represent the minimum water power possibilities of the Dominion.

As illustrative of this the detailed analyses which have been made of the water power resources of the provinces of New Brunswick and Nova Scotia have disclosed most advantageous reservoir facilities for regulating stream flow and it is estimated that the two provinces possess within their respective borders 200,000 and 300,000 commercial horse power. These figures provide for a diversity factor between installed power and consumers' demands.

Progress During Past Year

In spite of the outstanding facts that financial and commercial conditions are still far from normal and that costs of construction are almost prohibitive for all but absolutely necessary undertakings, there has been during the past year and is now, marked activity in hydro power construction. This has resulted from a variety of causes principal among which is the lack of native coal in the central industrial district and the fortunate location of economic water power sites to industrial centres.

The total hydro power development installed during the past year or now under construction represents approximately 560,000 h.p. of installed capacity. This figure includes only the initial installations of plants under construction, not their ultimate designed capacity. It is evidence of the manner in which the water power resources of the Dominion are being put to effective and productive use.

Future Growth in Utilization of Water Power

It is profitable to consider the history of water power utilization in Canada during the past few years in conjunction with the present activity with a view to making some reasonable forecast as to its probable future growth Should the rate of water wheel installation during the past fifteen years be maintained, there will be installed in 1925, 3,360,000 h.p.; in 1930, 4,110,000 h.p.; in 1935 4,860,000 h.p.; and in 1940 a total of 5,600,000 horse power. In view of the increasing appreciation of the advantages of hydro power combined with the fortunate location of ample supplies within easy transmission distance of practically every great industrial centre throughout the Dominion, there is every reason to anticipate that the rate of growth in utilization will be accelerated rather than retarded. Reference to the foregoing totals of water power available will indicate that this anticipated increase in utilization will not seriously reduce the total reserves. Canada possesses sufficient reserves of water power to meet all anticipated demands for many years to come.

TORONTO NO. 1. HOLDS PICNIC

Toronto No. 1 Lodge C. A. S. E., held a picnic on Saturday July 30 at the Exhibition Park Toronto which was unanimously agreed upon as being the best ever held. A large programme of sports had been arranged, there being thirteen events in all, and each one had a well worth-while prize attached to it. One of the best was the ball game between the engineers and supply men, which resulted in a draw, thus leaving no room for any blowing by either side.

The sports being successfully carried out, and the ball game decided without any casualties, adjournment was made to the Horticultcral Building, where the ladies had prepared a very appetising re past, which was much appreciated by the tired and hungry athletes.

A goodly number of the representatives of the various engineers supply firms were present, and co-operated as usual with the C. A. S. E. with regard to prizes.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

DOUBLE ACTING COMPOUND PUMP

Question:—We have a double acting compound pump, the high pressure cylinder of which is 11 inches, and the low pressure cylinder 16 inches. The pump runs thirty double strokes per minute, the boiler pressure being 115 lbs per square inch. The stroke is 10 inches. How do you figure the horse power, and if we do run this pump instead of two simple pumps what is the gain in efficiency.

Answer:—The horse power of the pump will be the product of the mean effective pressure on the area of each cylinder, multiplied by the stroke and the number of revolutions per minute, divided by 33,000. The formula will be—M. E. P. on high × Area of high × stroke in feet × 30 ÷ by 33,000 + M. E. P. on low × Area of low × stroke in feet × 30 ÷ by 33,000 which can be combined as follows:— M. E. P. of high× A plus M. E. P. of low × A × stroke × 30 divided by 33,000. The mean effective pressure of the high will be the forward pressure on the high pressure piston minus the pressure in the low pressure receiver, which will act against the high pressure piston all through the stroke. The mean effective pressure on the low will be the forward pressure on the low minus the back pressure, which will be slightly above the atmosphere in a non-condensing pump, and 5 or 6 lbs. above absolute vacuum in a condensing pump. In the ordinary pump the steam is carried the whole stroke at full pressure and then exhausted to the atmosphere, while in the compound pump the steam is further utilised in the low pressure cylinder before being exhausted, to atmosphere or condenser. The average efficiency of the steam in small pumps does not exceed fifty per cent, while with the compound or triple pump properly proportioned this will be much improved. Some compound pumping engines are arranged with a separate cut off valve on the back of the main slide valve so that cut off can be regulated. There should be a gain of from 10 to 15 per cent. in efficiency on a compound over a simple pump.

A REFRIGERATION QUERY

Question:—What effect does oil, air or water have in a refrigeration plant, and what provision is made to remove them?

Answer:—Air, oil or water in a refrigeration machine that is designed for using volatile liquids such as ammonia, or carbonic acid, have the effect of lowering the efficiency of the machine. The space occupied by these foreign gases or substances lessens the space for action of the ammonia. Oil on the coils has the effect of insulating them, and is just as detrimental to them as it is to the heating surfaces of a boiler, as far as heat transmission is concerned. Oil is removed from a refrigerating machine by means of oil separators placed in the discharge line and water can also be trapped in these separators. Air usually rises to the top of the condenser, and can be removed from there by means of purging, which is accomplished by opening a cock on top of the condenser, and flowing through a hose into a pail of water. While there is air passing its presence can be noted by bubbles rising in the water, and as soon as the air is out, the bubbles stop.

HORSEPOWER REQUIRED TO LIFT WATER

Question:— A round tank is 12 feet in diameter and 4 feet high, and is full of water. It is pumped 20 feet above the bottom of the tank in one hour. What is the horse power required?

Answer:—We do not quite understand the question as stated above, but we will give the method of finding out the horsepower, and it can be applied to any question. One cubic foot of water weighs 62.5 lbs and if this is raised one foot high by a pump or any other means, it will require the expenditure of 62.5 foot lbs of energy. A column of water 12 feet in diameter would have an area of 113-1 square feet, and if 4 feet high a volume of 452.4 cubic feet, which would weigh 28,275 lbs. This column of water is raised a mean height of 16 feet in an hour, as we understand the question, and the work done would be 28,275×16 which is 452,400 foot lbs. As one horse power is the performing of 33,000 foot lbs per minute, and the work in question has occupied one hour the horse power will be 425,400 divided by 60×33,000 or .22 H. P.

If the work were performed in one minute it would take 13.2 H. P. neglecting friction losses.

AMMONIA AND AQUA AMMONIA

Question:—What is ammonia and aqua ammonia, and why is ammonia so well suited for refrigeration and used more than anything else?

Answer:—Ammonia is a gas composed of Nitrogen and Hydrogen, there being one part of Nitrogen to three parts Hydrogen, and the chemical symbol is NH_3. It has the property of being easily liquefied at a comparatively low pressure and possesses a high latent heat. It is these properties which make it a suitable refrigerating agent, as the fact that it liquefies at a pressure of from 150 lbs per square inch enables the compressor to be built of ordinary thicknesses of metal, and the high latent heat gives it the power of absorbing a large number of heat units per lb of gas. It has also another highly important property for a refrigerating agent, that is a low boiling point. At atmospheric pressure it boils at 28.5 degrees Fahrenheit, while its latent heat is 592.1 B. T. U. Aqua ammonia is a solution of ammonia gas and water of about 26 degrees Baume, which corresponds to a specific gravity of about .897. This is used in the absorption process of refrigerating.

DESCRIBE A SUPERHEATER

Question:—Please describe a superheater.

Answer: There are a number of superheaters on the market, and we cannot describe any particular one. The general principle of a superheater is a number of coils, usually made of copper, which are placed in the uptake or breeching of a boiler in the path of the waste gases as they go to the stack. These coils are connected to the main steam discharge of the boiler, and all the steam passes through the superheater before going to the units in which it is to be used. As the gases in the uptake are at a temperature of from 500 to 600 degrees, and the steam at anywhere from 300 to 360 degrees, the steam absorbs a considerable amount of heat from the waste gases, thus causing it to be superheated. This means that the steam is at a higher temperature than that due to its pressure, and this heat will have to be given out before any condensation can take place. This extra heat is gained at the expense of what would otherwise be a waste. Superheated steam is generally used in turbine practice, and in some forms of drop valve engines.

Queenston--Chippewa Power Project Is Visited

Even On A Short Tour The Magnitude Of The Work Is Apparent —Seldom Does A Single Job Embrace As Many Branches Of The Engineering Trades As This One—Huge Shovel Is Employed.

By J. H. MOORE

A STUPENDOUS Engineering Undertaking." "A sight never to be forgotten." "Something of which Canada can feel justly proud." The above quotations are but three of the many expressed by the party of engineers and executives who viewed the Queenston - Chippewa development on Friday, July 22nd, under special arrangements made by the Ontario section of the American Society of Mechanical Engineers.

Seldom is a task undertaken that embraces so many engineering problems as the new power scheme we are speaking of. It is hardly necessary to state at this late stage of development what prompted the scheme. Everybody knows that the water will be brought in from the Niagara River, pass through a huge canal, later creating an enormous amount of power by its very volume. The problem of cutting a canal out of solid rock was itself a great one but practically every engineering trade enters into the successful completion of this project. The mechanical, electrical, structural and hydraulic branches are the chief ones interested, with the transport, and housing problems coming as secondary, yet important considerations.

Important Figures.

Before proceeding with the story of the trip itself, we will briefly review the more important figures connected with this great power scheme. When completed the power plant will consist of 9 units with 500,000 h.p. The effective head on the water is 305 ft., and the capacity of each power unit is 55,000 h.p. The length of the river section is four miles, and the length of the canal 9 miles, making 13 miles in all. The cut in both rock and earth is enormous, being 72 ft. in the earth and 85 ft. in the rock. The concrete water channel is 48 ft. wide, and under normal operations the depth of the water in this channel will be around 30 to 35 ft.

The maximum velocity in the canal will be 10 ft. per second, and the forebay, which is 1,000 ft. long, widens from the standard 48 ft. canal section to 500 ft. at the gate house. The penstocks used are 16 ft. in diameter, and not only is every joint riveted, but it is welded as well.

The power house when completed, will be 600 ft. long and 185 feet high from its base. They figure the total earth excavation will be 13 million cubic yards, and the total rock excavation 4 million cubic yards. Work was really commenced on this project in May, 1917, and since that time great progress has been made.

To illustrate the detail necessary in a project of this kind, we will review very briefly some of the arrangements necessary to carry on the work. Seventeen highway and railway bridges have been built, two dredges and 14 shovels are used, also a cableway excavator. The writer viewed with interest the largest electric shovel ever made, working like a trojan on the job. Each bucket full means 8 cubic yards of earth and rock, and in some cases the material is lifted as high as 80 ft. Three trips of this shovel and a dump car is full of material.

Eighty miles of railroad track have been laid, and over some of these lines passes more traffic than on many a line owned by a large railway company. 24 electric locomotives are used, 26 steam locomotives, and over 320 air dump carts.

The various concrete plants have capacities as follows: The crusher plant has a daily capacity of 3,000 cubic yards, the sand storage a capacity of 100,000 cubic yards, with a stone storage capacity of 250,000 cubic yards. There are 9 stationary concreting plants, 4 movable paving plants, and 9 movable lining plants.

Compressed Air.

The compressed air wants are well looked after, there being some 26 units electrically driven, which provide 30,000 cubic ft. of free air per minute. Over 500 temporary buildings are erected, and there are five camp districts for employees, providing accommodation for 6,000 men. With few exceptions electric power is used to drive the machinery at work, and the normal load for constructional purposes is 10,000 K.W.

Leaving these amazing figures to sink in, we will proceed to tell the story of the actual visit. The first place inspected was the power house. Here was to be seen some wonderful concrete work, both in the building itself and in the draft tubes, and ice chute provided. The form work on some of this work is nothing short of marvellous and shows what really can be accomplished with concrete. Without dwelling at length on any particular part of this portion of the plant, the party viewed the turbines, the various electrical units in connection with it. The penstocks with their massive proportions and extreme height came in for quite a lot of comment, and the men working on the face of the solid rock looked like mere ants scrambling to and fro.

After dinner the screen house was inspected together with the wonderful system of handling the pouring of concrete. The method of transporting the various materials used is wonderful. Conveyors are used for everything. Central stations distribute the prepared material to the different parts of the job, and once started, the flow is continuous until that particular portion is completed. The pouring tubes around this job are almost numberless, and they are controlled by gates operated at some central spot. In the case of the sand and stone, they go to a storage station, from there to the mixer or to some subsidiary point, but in the case of the cement, a conveyor takes it direct from the car to the various mixing plants.

Change in Shape.

From this point on the party stopped numerous times, inspecting the canal at different points. At one portion the canal channel changes from a trapezodial shape to a rectangular shape, or vice versa, as you would prefer. This is where the old bed of the Niagara River is crossed, and instead of a rock cut, this portion is an earth fill, this fact accounting for the change in shape. The concrete work is so arranged that the form again gradually assumes a rectangular section as rock is once more met with.

At another point in the canal, a certain necessary curve has been so figured out that the heat loss suffered in winter by the friction of the water passing round this curve will prevent thin ice sticking to the side of the channel. Readers of course will not care to go into how this was arrived at, but it shows how much care has been exercised in the preparation of the canal.

When completed the channel will have a gradient of 1 ft. per mile, and the water will flow at a rate of about 7 miles per hour. At first only two power units will be installed, and a flow of water 6,500 ft. per second will be all that is required for these units.

In some of the concrete work on the canal channel portable forms are used, this being on the trapezodial shaped portion. These forms are merely placed on top, the concrete poured, and in twelve hours the form can be safely lifted. For the main channel, that is the rectangular shape, special concrete pouring machines are used, these having steel forms on either side which are set the correct distance apart, and poured right from the machine, which is self contained. This machine runs on portable tracks on the bottom of the canal channel, and it is a treat to see it work.

The method of blasting rock is particularly interesting. Portable air drills go down for a depth of between 20 to 30 feet in the solid rock, and holes are drilled about every 6 feet across the channel bed. After drilling, the various holes are loaded with explosives, "Forcite"

High Speed High Efficiency Engines

Allen "Open" and "Enclosed" high-speed engines have a world-wide reputation. They are being extensively used by the British and other principal Naval Powers of the world, as well as by the Mercantile Marines of all Countries, for driving auxiliary machinery on board ship.

Many thousands of these engines have been supplied, working in connection with installations of electric light, power and traction, serving in Municipal Corporations' and Electric Lighting Companies' Stations, Dockyards, Arsenals, Mills, Factories, Mines, Steel Works, Quarries, Sugar Refineries, Chemical Works, etc., and are giving uninterrupted service at low cost.

Allen Engines are suitable wherever high speed, high efficiency engines are required.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

QUEENSTON-CHIPPEWA POWER PROJECT IS VISITED

(Continued from page 39.)

being chiefly used, and the charge is set off electrically. The huge 8 cubic yards electric shovel then comes along and bites right into that depth.

The dredge "Cyclone" works away at the inlet to the canal, clearing away the earth, so as to allow the proper volume of water to pass through. In fact, to tell the tale properly and in detail would take a volume in itself. Even the huge stone crusher could take a lengthy description. There it appears, a massive mass of machinery, nothing to see inside, but crunch, crunch, crunch, it goes on, eating rocks and breaking them up like we would an ordinary chocolate. There is a spirit of romance to the whole venture, and one cannot help but feel the thrill of at least having seen such a wonderful work being performed.

Col. Ellis was the chief guide, being ably assisted by Mr. Tobias, one of the designing engineers on the work. Twenty-one took advantage of the trip, these being H W. Price, Professor of Electrical Engineering, University of Toronto; W. F. Sutherland; Professor Gilchrist, of the Physics Section U. of T.; G. M. Smith; L. Tolson, and J.H. Moore, all of Maclean Publishing Co.; Col. A. D. Lepan, Supt. of Bldgs., U. of T.; Mr. Spradbron; Mr. Lewis, Supt. Machine Shop, J. Inglis Co.; Mr. Quesnell, boiler inspector; Mr. Howard, John Bertram and Sons, Dundas; Mr. Graham of the same firm; Prof. Angus, professor of mechanical engineering, U. of T.; Harry Angus, Senior, retired constructional engineer; G. H. Raitt, Massey Harris Co.; Chester B. Hamilton, Jr., Hamilton Gear and Machine Co.; Mr. Crane; Mr. Boswell and Mr. Moody of Powley and Townsley, Toronto.

ANNOUNCEMENT

The Canadian Chicago Bridge and Iron Company, Limited, of Bridgeburg, Ontario, and Montreal, Quebec, has changed its corporate name to Horton Steel Works, Limited, according to an announcement made by C. H. Scheman, general manager of the company.

The new name has been selected in honor of the late Horace E. Horton, who founded the organization in the United States in 1865. The Canadian organization was first incorporated in 1913 and the plant at Bridgeburg, Ontario, was constructed in that year.

Mr. Horton was one of the pioneer engineers of North America. Starting with a timber bridge at Orinoco, Minnesota, in 1865, Mr. Horton developed a large business in the design, fabrication and erection of bridges, steel tanks, etc. In the early nineties, he revolutionized the steel tank business by inventing the hemispherical-bottom elevated tank of which thousands are now in use throughout the world. A few years ago his son, Mr. George T. Horton, now president of the Horton Steel Works, Limited, invented the elliptical bottom tank with riveted steel riser which was a further advance in the art of steel tank building.

The corporation has supplied the railroads and many industrial organizations of Canada with plate metal products. The company has a tried organization with its own operating officials, a complete plant, erection forces and contracting organization. In addition to Mr. Scheman, Mr. G. S. Sangdahl is district sales manager at Montreal, Mr. C. C. Gregory is manager of plant, and Mr. F. E. Gregory superintendent of erection. The main office and works are at Bridgeburg, Ontario.

NEW BOOKS

The Combustion Engineering Corporation have printed in booklet form the paper read before the American Iron and Steel Institute in New York in May last. This is stated by the Combustion Company to be the most complete summary of powdered coal progress that they have yet issued. The paper describes in detail the various types of equipment, the results achieved up to the date of the paper, and a general history of the progress of this new method of using coal fuel. The booklet is issued with the compliments of the Combustion Engineering Corporation, Broad Street, New York.

DEFEND YOUR STEAM

The Magnesium Association of America have issued a book with the above title, setting forth the merits and uses if 85 per cent magnesia. In the preface it is stated that the book is for the use of the architect, engineer, and owner, to assist them in the conservation of fuel by proper insulation of steam pipes, boilers and any surface which might radiate heat where not so required. Short articles on heat insulation and losses, and the proper type of insulation to use in different situations and circumstances are indicated. A goodly number of illustrations are included, several of them being of plants in Canada.

STEEL SLITTING SHEAR

A special design of bench shear intended for use in machine shops, garages, etc., has recently been developed by the Dries & Krump Manufacturing Co., of Chicago, Ill. It has a capacity for cutting bars up to 3-16 by 2 inches, and will slit steel sheets up to No. 10 gauge. The shear is of all-steel construction, the frame being pressed out of one piece and offset to allow working on sheets of any length. Geared leverage is provided. The blades are 4½ inches in length and 5-16 inch thick, made of crucible steel. All parts are made interchangeable.

--and who wants to waste steam at present prices of coal?

With coal costing as high as $13 a ton—and often hard to get at any price—it is far cheaper to put in enough Steam Traps Sarco to stop loss of steam through condensation than to stand the alternative of big waste at the coal pile.

Steam Trap Sarco puts the whole question of proper trapping vs. waste of coal on an entirely new basis—

It pays for itself at points where a Big Trap wouldn't Be Justified.

You can put in three Sarcos for the cost of just one bucket or floor trap—thus for the same expenditure saving three times as much steam and therefore three times as much coal. Because it costs only one-third as much, a Sarco will quickly pay for itself at points where the expense of an old-style trap wouldn't be justified.

Sarco is more dependable and efficient than old-style traps. It operates automatically—on a simple yet extremely sensitive and responsive system of liquid expansion and contraction. So positive in action that not an ounce of live steam can escape from one year's end to the other.

Drains off all condensate as fast as it forms—and immediately returns it to the hot well—while still hot, thus requiring less coal to convert it back into steam. And never any water (condensate) left in the pipes to freeze overnight or over Sunday.

30 DAYS' TRIAL.

We are ready to let Sarco demonstrate its superiority and economy right in your own plant by sending you one on 30 days' free trial without a cent in advance. If for any reason you aren't satisfied with its performance, you can return it and it won't cost you a cent.

Made in sizes ⅜ in. to 3 in. for any given pressure up to 200 pounds.

Booklet No. J-12 and full particulars about our free trial on request.

WHY DOES A BELT CLIMB

Editor. Power House:—

I have just finished a big discussion with a group of engineers on the question of belts running to "the high side of the pulley" as they put it, and I herewith give you my views on the problem.

I would like to say that such expressions as "the belt will run to the HIGH side" or "the belt will run UP" are erroneous expressions because the belt only runs "UP" or to the "HIGH" side SOME times; depending on what causes the UP or HIGH sides.

Now what a belt always does without fail is to run to the LARGEST diameter; and that for good and scientific reasons.

When one edge of a belt runs on a larger diameter, that edge of the belt is pulled over the pulley at a higher rate of speed than the other edge which produces a bending effect edgewise on the section of belt approaching the pulley, thereby CHANGING THE ANGLE at which the belt rolls onto the pulley surface. This new angle of approach cuts the belt across the pulley face, until the centre of the belt has reached the greatest diameter of the pulley where both edges will travel at the same speed and the belt will approach the pulley in a straight line and remain in that location. This is the principle of the crowned pulley and because engineers are so accustomed to seeing belts climb up onto the high part of the pulley face, many of them very wrongly come to the conclusion that the belt will climb onto ANY high portion of the pulley face

If two pulleys with straight faces are mounted opposite each other on shafts that are out of parallel but in the same plane the belt will run off the low side always instead of climbing to the high; for the principle is the very same as if the belt were stationary and the pulley were rolled along the belt, it would roll off the belt on the side towards which its angle inclined.

Now try that same test on a crown-faced pulley, only instead of rolling it along a belt, roll it along a railway made of two small strips of wood or metal laid side by side on the floor a few inches apart. The pulley will be found to straighten itself on the track even if started off on an angle, and to follow the track even if the track be curved—within reason of course.

The claim made by some of my friends that "mechanical action takes place along the lines of least resistance" is perfectly correct, but the belt is FORCED onto the larger diameter by the power of the motor which is driving it. The principle involved is the principle of the screw and while a house-jack would more easily lower the building than raise it, yet if the force driving the screw is applied in the lifting direction then UP the building must go.

Yours very truly,
R. Manly Orr.

1551 Granville Street,
Vancouver, B.C., Canada.

Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap

Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admissions of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds.

Being open at starting, it cannot become air bound, this doing away with air cocks or vents — Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

This one pipe wastes enough coal to fill every basket in the line

From a painting by Howitt showing one of the coal lines during the "shortage" when even limousines called daily for the allotted bushel. And yet the majority of people in the line were guilty of wasting tons of coal in the manner described.

IT isn't coal shortage that causes sights like this—it's coal waste.

For a sealing up of waste would instantly double our available coal supply.

But all wastes are not in homes—many power plants waste car after car of coal through pipe insulation that is faulty, physically weak or improperly applied.

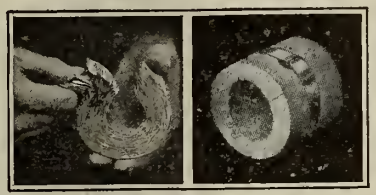
This is largely because in the early days pipe covering simply meant putting something on heated surfaces to keep some heat from escaping. Buyers neither asked nor expected assurances of how much it would save. So when Johns-Manville developed accurately rated insulation, engineering supplanted guesswork.

You can now know what bare heated surfaces and pipes are costing—also to what extent the insulation you now have is effective as a heat saver.

But had Johns-Manville been content to stop its research after high heat savings had been achieved, as in 85% Magnesia, the still more desirable insulation shown in the left hand picture below would be unknown.

This Johns-Manville Asbesto-Sponge Felted Insulation marks the success of an endeavor to increase *the life* of insulation without sacrificing heat saving efficiency. It is more durable than the older moulded forms for it is built up in felted ply form so that it does not grind away under vibration, or in handling, and more remarkable still—it shows the highest heat saving efficiency of all commercial materials.

Look about you for bare hot surfaces. You can be fairly certain that the heat they waste will soon pay the cost of insulating them with the materials below which we will prescribe and apply for you.



Showing how the felting of Asbesto-Sponge gives flexibility so vital to long life.

Johns-Manville 85% Magnesia—the standard of the moulded class of insulations.

Other Johns-Manville Insulations *include Asbestocel of the cellular type, Anti-Sweat to prevent condensation on cold-water pipes, Zero Insulation for cold-water pipes, Ammonia Insulation, Underground Conduit Insulation, Furnace and Boiler Insulation, and Insulating Cements.*

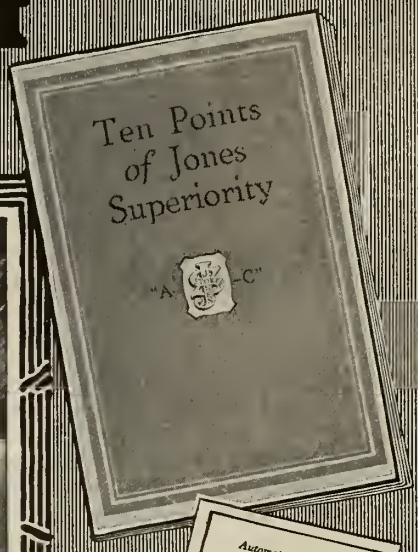
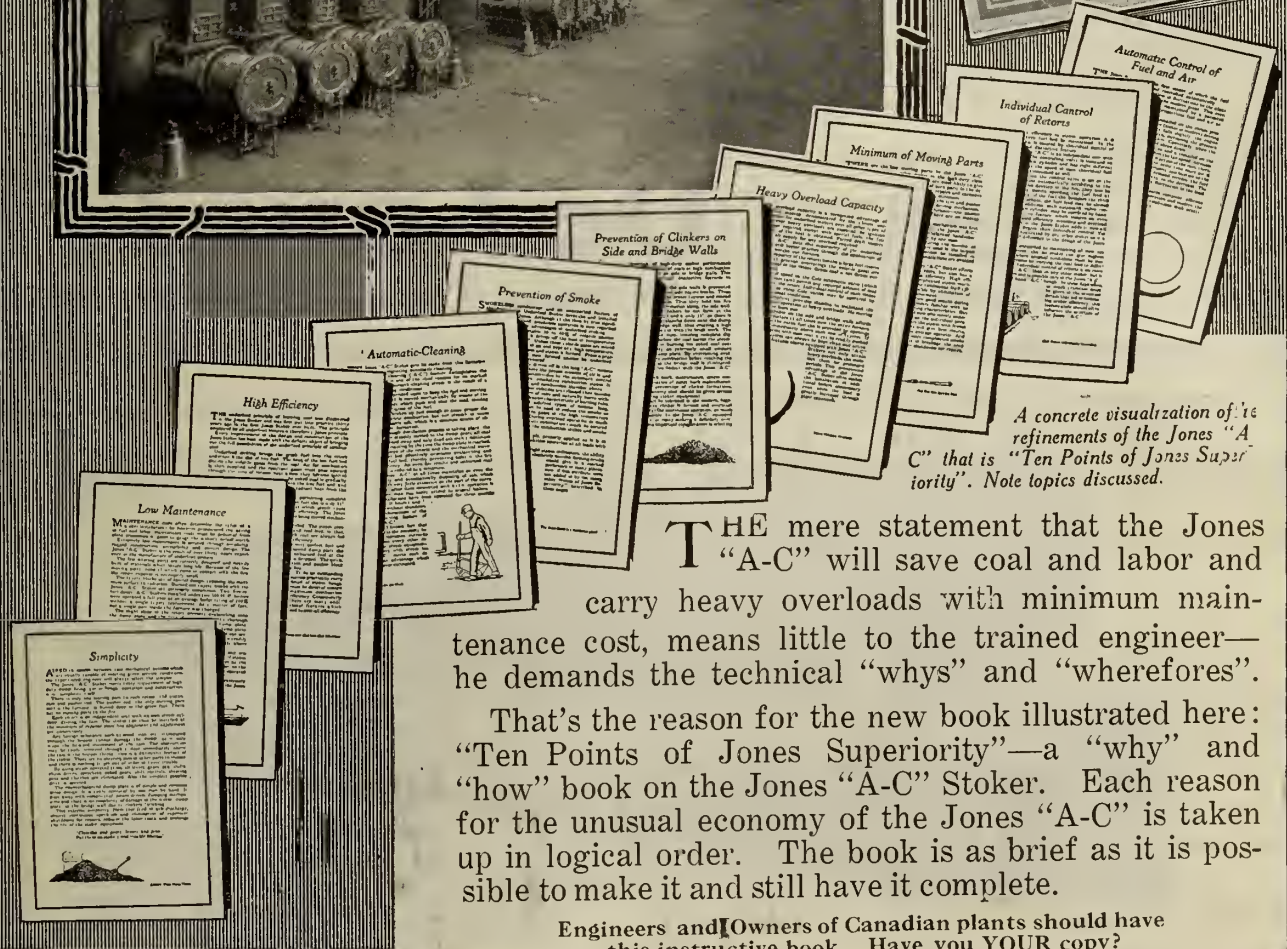
Each "Point" is a part of every installation





A concrete visualization of the refinements of the Jones "A-C" that is "Ten Points of Jones Superiority". Note topics discussed.

THE mere statement that the Jones "A-C" will save coal and labor and carry heavy overloads with minimum maintenance cost, means little to the trained engineer—he demands the technical "whys" and "wherefores".

That's the reason for the new book illustrated here: "Ten Points of Jones Superiority"—a "why" and "how" book on the Jones "A-C" Stoker. Each reason for the unusual economy of the Jones "A-C" is taken up in logical order. The book is as brief as it is possible to make it and still have it complete.

Engineers and Owners of Canadian plants should have this instructive book. Have you YOUR copy?

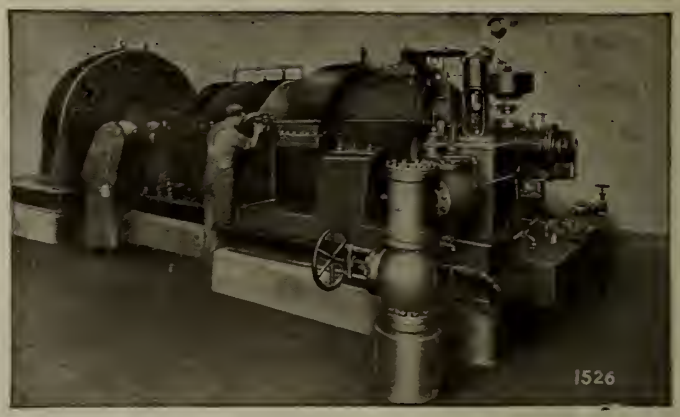
Power *For* Auxiliaries



THIS 1500-KW., De Laval geared turbo generator supplies direct current for the operation of auxiliaries in the Delray Plant of the Detroit Edison Company. The turbines operate on steam at 225 lbs. pressure and 210 deg. F. superheat. The steam is exhausted into a varying vacuum of from 24″ to atmospheric exhaust. The condenser is a barometric condenser and the circulating water used is the condensate from the main generating units.

This arrangement gives high plant economy combined with the flexibility and easy control of electric driven auxiliaries.

In such service high efficiency and reliability are paramount. Every De Laval unit is guaranteed as to efficiency and is thoroughly tested at our works before shipment. Our engineers have had extensive experience in adapting the steam turbine to increase plant efficiency and would take pleasure in applying their information and skill to your conditions.

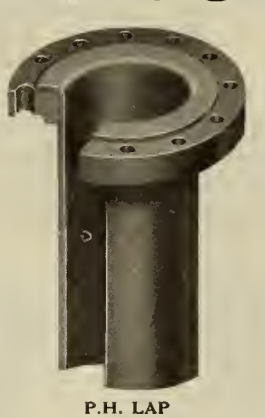
P H FLANGED PIPE JOINTS

SCREWED



P.H. LAP

P H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

Feed Regulation Planned Scientifically

Every boiler plant presents its own problem in boiler feeding. To meet specific operating characteristics with assured efficiency requires careful study of the operating conditions before the proper automatic feed regulation can be applied.

Our engineering department specializes in this class of work and offers its service to power plant owners and engineers without charge or obligation for recommendations.

COPES BOILER FEED REGULATORS automatically maintain the correct relation between the rate of feeding, the steam demand and the furnace condition. Each Copes is designed for the specific conditions governing the boiler—the control valve is neither too large nor too small.

This insures maximum efficiency. Finally, the guiding force of the Copes is great in proportion to the internal resistance of the regulator, so as to insure smooth and continuous opening of the regulating valve and not a "step by step" motion."

Write for Bulletin "D."

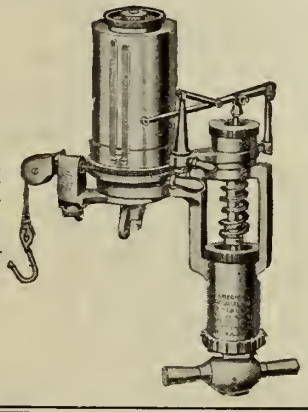
Don't Just "Run" an engine *Know* It!

To be a big and successful engineer you must do more than merely **run** your engine. You must acquire an intimate knowledge of its workings through the

AMERICAN THOMPSON IMPROVED INDICATOR

Here are some of the things that the American Thompson Indicator will tell you about your Engine—things that you ought to know:

Piston pressure at every point of the stroke
Drop-in pressure between boiler and cylinder
Exact horsepower developed
Exact consumption of water
Waste of coal
Leaking valve
Leaking piston
Improperly set valve
Power demanded by full load
Power wasted at low load
Cost of running idle
Loss caused by improper piping, etc.



Can you afford to be without an instrument which makes it possible for you to maintain complete mastery of the plant you operate?

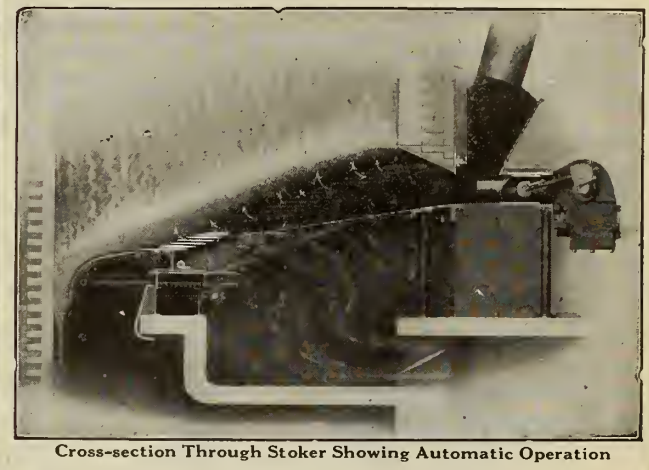
BURN ALL GRADES OF COAL



Cross-section Through Stoker Showing Automatic Operation

No device has shown itself better adapted to burn any available coal than the

RILEY UNDERFEED STOKERS

Low-grade coals—those high in ash—in sulphur and clinker-forming qualities—can be handled successfully for the following reasons:

1. The moving grates keep the clinkers broken up—combustion is intensified—the fuel bed is always active, even and in a homogeneous state.
2. The rocker dump, with its combination of vertical thrust and rocking motion, grinds up—discharges the ash continuously and automatically—keeps the fire clean and the bridge wall free from accumulations.
3. The underfeed feature makes possible high capacity and instant response to overload demands.

Our engineers will be glad to acquaint you with the wide range of fuels now being handled by the RILEY UNDERFEED STOKER under many varying conditions.

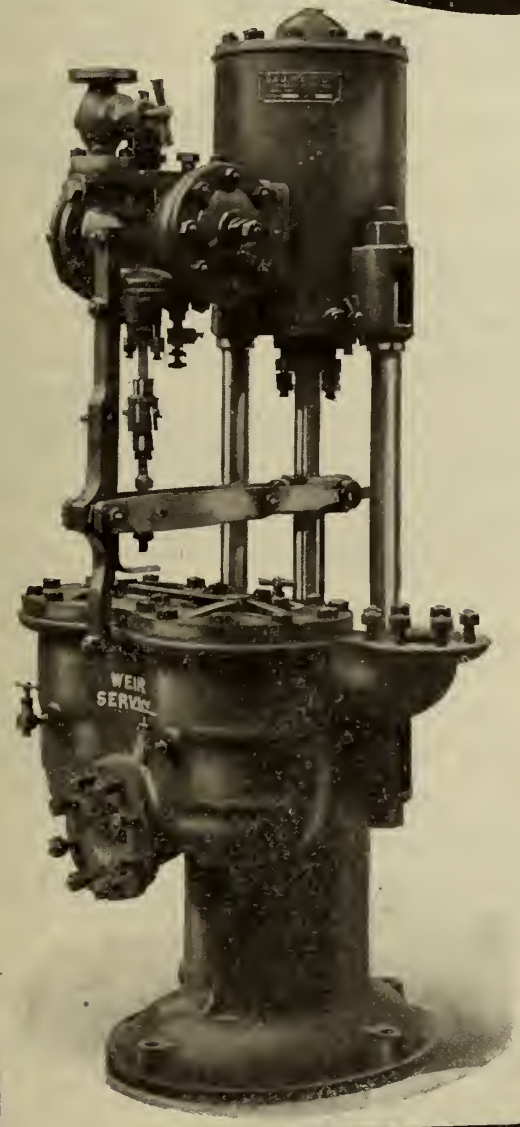
WEIR AUXILIARIES



WHEN someone builds a Pump that is absolutely perfect we hope it will be G. & J. Weir (Canada) Limited. in the meantime we are confining ourselves to building pumps that are as **nearly perfect as possible**—pumps that give their owners more than ample return for the investment.

Single Acting Simplex Feed Pumps
Turbine Rotary Feed Pumps
Compound Feed Pumps
General Service Pumps
Direct Contact Heaters
Multiflow Heaters
Evaporators and Distillers

Coupled with Weir Auxiliaries is Weir Service Research, designing, manufacturing and operating data—the results of years' of concentration—are available to every Weir client.

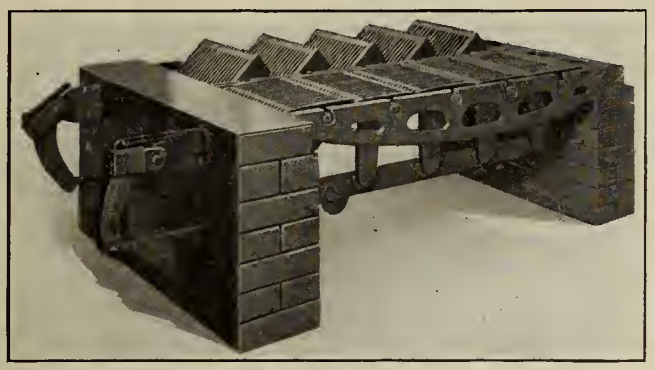
Strong and Sturdy

Adaptable to Any Size Boiler

All Sizes in Stock

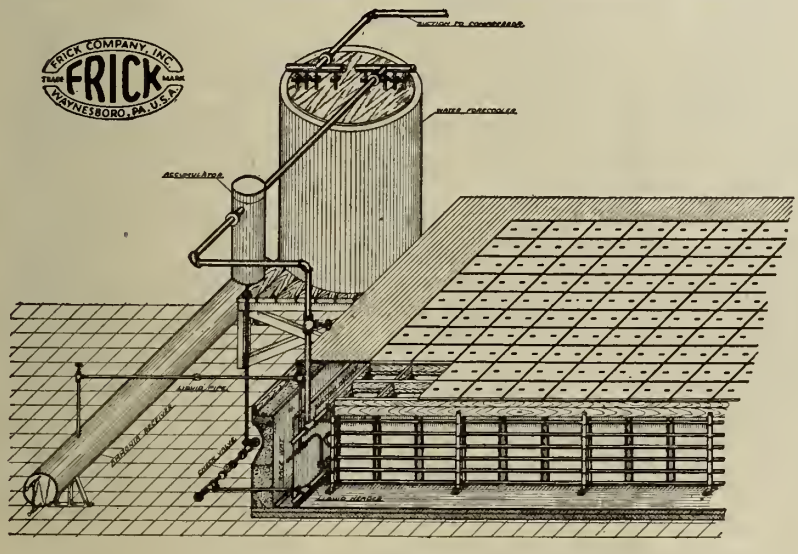


THERE'S EASIER ACTION AND LESS WEAR AND TEAR WITH

Superior Grates

Let us replace your worn out grates with these strong and sturdy Superior Grates. Have more air space than any other grate on the market, therefore you will have a better fire and use less fuel. Prompt delivery. Write for particulars.

PHILIP GIES FOUNDRY
KITCHENER, ONT.



The FRICK FLOODED SYSTEM

Is a STANDARD Part of Every FRICK Plant

Its simplicity and dependability have made it a Standard known the world over. Its success is unqualified.

It

- Simplifies plant operation by reducing the number of feed valves to be regulated.
- Increases plant efficiency by insuring uniform operation and giving absolute control of the ammonia.
- Adds to plant safety by preventing priming accidents.
- Lowers first cost of plant by increasing the heat transfer through the evaporating surface, thus reducing the amount of surface required.

Ask for a copy of our List of Users covering 48 pages of satisfied customers — also your copy of Ice and Frost.

Frick Company
WAYNESBORO, PA. U.S.A.
ICE MACHINERY SUPERIOR SINCE 1882

BRANCHES IN ALL PRINCIPAL CITIES

There is a FRICK Machine for every refrigerating purpose — all types Vertical — Horizontal — Absorption.

Canadian Representative: FRICK Ice and Refrigeration Co., Montreal

EMPLOYERS! BUSINESS MEN! EMPLOYEES!

What Can We Do For You?

Here's what we have done for others:
Sold machinery and power house equipment of all kinds.
Brought together employers requiring men to fill positions, and employees seeking positions.
What we have done for others, we can do for you.
Our classified rates are as follows:
2 cents per word, with a minimum charge of $1.00 for fifty words or less.
Secrecy is secured by using a box number, which counts as five words.
This is your department of service and we can help you if you give us the opportunity.
TRY IT!

Godfrey Monorail I-Beam Installation at Van Camp Packing Co.

Handling Coal and Ashes at Low Cost with a Godfrey Conveyor

THE Van Camp Company at their plant pictured above have been using a GODREY CONVEYOR for two years to unload, store and reclaim their coal. The same system is used to carry their ashes from boiler room to an outside tank. During the time they have saved a considerable amount of money on the items of labor, demurrage charges and wasted time. Their coal is unloaded from car to storage by the service of only ONE MAN. No shovelling is required. Their Superintendent stated the cost of conveying coal to bunkers in boiler room is only SIX cents per ton.

Your Company Can Do the Same

Godfrey Canadian Engineers will be glad to make recommendations and estimates. No obligation whatever. Just tell us or them where and when.

LUNKENHEIMER
"Ferrenewo" Valves

"FERRENEWO" Valves are *economy* valves, proved so by their record of years in service. Low initial cost, wear resisting materials and the ease of renewal of all the parts should necessity require, makes them highly desirable for piping equipment where the pressure does not exceed 150 pounds.

LUNKENHEIMER "Valve-iron" from which "FERRENEWO" Valve bodies are made is an especially alloyed and processed Ferrous Composition. The renewable *seatring* and *disc* are made of LUNKENHEIMER "Valve-nickel," while the bonnet, stem and bonnet ring are made of bronze compositions formulated especially for the duty each part performs.

The "FERRENEWO" material combination and unique design, coupled with the LUNKENHEIMER method of manufacture insures successful results under the wide range of operating conditions for which "FERRENEWO" Valves are adapted.

LUNKENHEIMER Distributors situated in every commercial center carry "FERRENEWO" Valves in stock for immediate delivery.

To standardize on "FERRENEWO" Valves is to *economize* in valve cost and maintenance.

Low Cost Coal Storage with "LABRIDE" Equipment

If you are unloading coal by hand, the "LABRIDE" Equipment will save you from 70 to 95 per cent. of your coal handling cost. This equipment consists of a moving bridge traveling lengthwise of the storage space and a bucket trolley traveling crosswise on the bridge,—thus every square foot of storage space is covered with a minimum of movements and time. The "LABRIDE" Equipment is the fastest, most efficient and economical method known in coal handling today. Capacity varies from 60 to 90 tons per hour.

Write or wire for information.

REFINITE

RIVAL OF THE CLOUDS

TRADE MARK

NATURE'S WATER SOFTENER

Trade Mark Registered

Investigation Proves Its Superiority

WHENEVER forethought and serious investigation are employed in considering the claims of Water Softening Systems, REFINITE is invariably accepted as the superior. The fact that REFINITE mineral is a *natural* Water Softener is of prime importance. No other water softening system has REFINITE mineral. The working mines and untouched deposits are the exclusive property of the Refinite Company.

Actual Size of REFINITE Mineral Grains

This is a photographic reproduction of REFINITE Water Softening mineral. REFINITE is a *natural* water softener—not an artificial or chemical product. Note especially the large size of the grains. No gravel bed is needed, hence more mineral can be used. This means longer service without regenerating. Furthermore, no mineral is lost in cleaning

Every feature of construction in REFINITE Water Softening Systems is *better*, because the priceless possession we have in Refinite mineral demands a practical system built of the highest grade material. No makeshift will do! Refinite has set a standard by which all other water softening systems are judged.

Owners of Refinite Water Softening Systems know they have the *best!* Let their testimony be your guide in deciding on the system you should install. The economy and convenience of soft water is appreciated by everyone, especially for use in laundries, hotels, hospitals, textile mills, etc. Your one problem is to install the *Best!*

Write for Free Booklet and complete information. Address office nearest you, or phone if convenient. Asking for the full details does not obligate you in any way.

We also manufacture Booth Lime-Soda Softeners and Refinite Rapid Pressure Filters.

Ask Dun or Bradstreet About Us

This is the Patented REFINITE Strainer-Valve, scientifically made to withstand action of salt and water. *An exclusive Refinite patent*

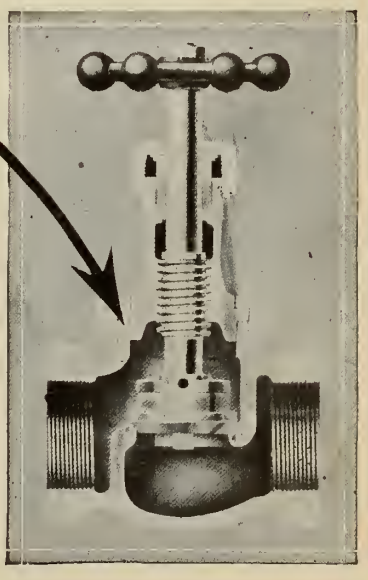
ALL PENBERTHY VALVES HAVE THE EXTERNAL THREAD CONSTRUCTION

"QUALITY FIRST"



Government Approved for 175lbs. Steam Pressure

Government Approved for 200lbs. Steam Pressure

THE EVER INCREASING POPULARITY

of Penberthy Valves is due to the fact that the name "Penberthy" stands for quality and service.

THE OUTSIDE BONNET

construction found in all Penberthy Valves, the first improvement made in valve construction in generations past, proves that Penberthy Progress is in keeping with new and improved ideas.

The design, workmanship and finish, and the long and efficient service which all Penberthy Valves give, proves beyond question that no efforts have been spared to give to the engineering profession a better valve at no greater cost.

WEIR AUXILIARIES

A Safety Slogan Reads--

"This is one of the peculiarly dangerous months in which to take chances. The other months are the remaining eleven."

A good slogan to remember when purchasing, for in these days of competitive prices you can ill-afford to invest in goods of uncertain calibre. 65,000 Weir Pumps successfully performing on 65,000 jobs remove the chance element from Weir investment. Weir interchangeability of parts plus Weir Service keep that chance element out for 12 months of every succeeding year.

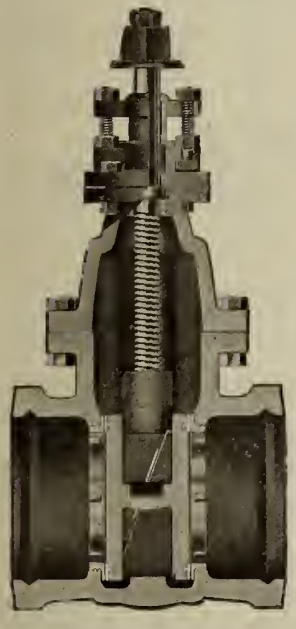
Some Distinctive Qualities of the

DARLING
PATENTED
Gate Valve



Made in Canada

PARALLEL SEATS - Are renewable and have ground-in faces.

REVOLVING DISCS - Insure long wear because they seat at a different place each time valve is operated, avoiding unequal wear.

WEDGING MECHANISM - Carries the discs over the port and in front of their seats before spreading and releases the discs from their seats before they start to rise.

STUFFING BOX - Bolted pattern with independent gland bolts.

LARGE VALVES - That are operated in a horizontal position require no auxiliary mechanism for carrying the internal parts. The Discs themselves roll like two wheels and carry the wedges.

EASILY OPERATED - Because all the parts are perfectly plain and have no pockets or places where sediment can collect to prevent their free and easy movement.

Licensed Manufacturers in Canada

Perfect Service Gasket Material

Guaranteed to make a Tight Joint wherever a Permanent Gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown.

DURABLA
TRADE MARK REGISTERED

Strength; Goodness; Quality - these features distinguish Durabla Gaskets.

DURABLA Sheets can be rolled and unrolled; it never dries out or opens up.

DURABLA Compressed Asbestos Fibre Gasket Material is a guaranteed product that can be used as a standard for all Gasket work. DURABLA Gaskets make tight joints on Steam, Water, Oil, Ammonia and Acids at all temperatures and pressures.

DURABLA is not affected by vibration or condensation. It will not burn out, blow out or pulp at the points.

Let us send you a trial sample. Made in stock sizes 36 in. wide x 144 in. long, and 48 in. wide x 144 in. long, in thicknesses of 1-64, 1-32, 1-16, 3-32, 1-8.

Orders Filled Promptly.

What Lubricants Do You Use?

PROPER plant lubrication is important. The selection of lubricants merits careful consideration. The reputation of Imperial Lubricants has been honestly earned by the many years of satisfaction rendered to Canada's more important industries.

Insist on a lubricant with the Imperial brand. Make sure that you are using the right grade and you will cut lubrication costs, reduce repair and upkeep expenses and increase the output of your plant.

The question is, not how many gallons, but it is, *how much lubrication* you get for your dollar. Poor lubricants are expensive at any price. Imperial Lubricants are carefully formulated and are always of uniform high quality.

You will find a lubricant exactly suited to every bearing and every unit in your plant in the list at the right. Standardize on Imperial Lubricants. Supplies always conveniently available.

Imperial Lubrication Engineers will gladly advise with you regarding any lubrication problem. Write to 56 Church St., Toronto.

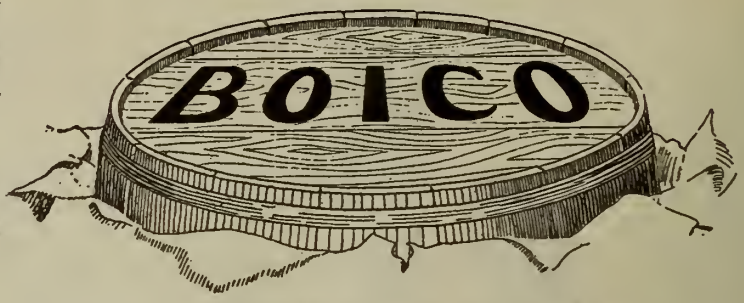
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

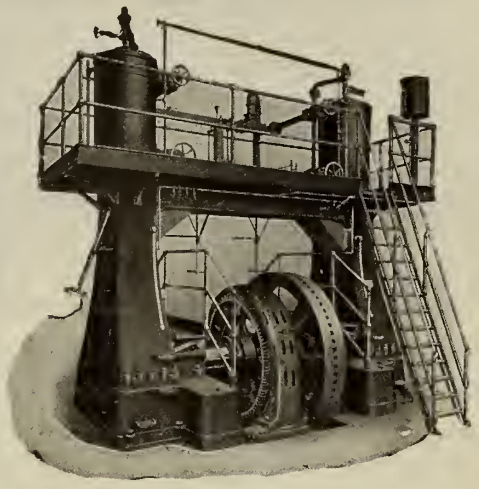
QUALITY YORK SERVICE

York Semi-Enclosed Refrigerating Machines

The Raw Water Ice Plant is rapidly taking the lead, and its development demands an Ammonia Compressor that is most economical in Power Consumption.



Where electric current is available at a reasonable cost, our Semi-Enclosed Machine, with direct motor mounting, makes a neat, clean and highly economical plant—no belts, no engine or steam lines.

The machine occupies a comparatively small floor space.

All the power developed by the motor is delivered to the crank-shaft of the machine.

These machines are built in sizes from 30 tons refrigerating capacity upwards.

Mr. Engineer, are you--

one of those wide-awake, up-to-the-minute engineers who is willing to be shown how economies can be effected in the boiler room? Many power plants in Canada and the United States, especially noted for high operating efficiency, consider "Bailey" meters essential to the best operation of either coal or oil-fired furnaces.

Bailey Boiler Meters

"Bailey" Boiler Meters—the coal savers—record the true relation between the coal and air supply to the furnace and plainly show the men what adjustments to either are required to maintain high operating efficiency and economy.

CHARTS SHOW PERFORMANCE OF INDIVIDUAL BOILERS

and tell when a boiler requires cleaning or inspection for leaky tubes or broken baffles. You can check the work of the fireman at all times.

Try one "Bailey" Boiler Meter and you will soon order "Bailey" equipment for all of your boilers.

May we send full details? Tell us your requirements.

YARWAY

Seatless Blow-off Valve and Double-Tightening Valve in Tandem Arrangement

A combination first developed to meet A. S. M. E. boiler code and boiler laws in certain states—that is ideal for blow-off service in any state.

The Yarway Blow-Off Valve is a slow opening, seatless valve that does away with the seat troubles of the old type valves and that automatically tightens the packing after the valve itself has closed, and releases the packing before valve starts to open.

The Yarway Double-Tightening Valve is a quick opening valve with the unique feature of a sealing bushing on the inlet side which makes the valve double tightening on both sides of the swing gate.

With both valves in place the blow-off line is doubly guarded. Highly successful installations of this type are numerous. B-410 is a handy booklet that will show you the unusual features of the Yarway Valves in detail. To whom shall we mail it?

IT PAYS!

It means money in your pocket to line your furnaces with

PLIBRICO JOINTLESS

FURNACE LINING

A perfectly air-tight, gas-tight furnace lining, such as is yours when baffles, side walls, bridge walls, and front door arches are constructed of PLIBRICO, gives you many opportunities to save.

You save fuel, for in jointless PLIBRICO there is no chance for costly heat units to escape. You need pay only for the fuel you burn.

You save time, for there are no shutdowns for repairs when PLIBRICO has been properly installed and vitrified.

You save labor, for any man about the plant, who can wield mallet and trowel, can install PLIBRICO settings.

Let us tell you more about PLIBRICO. Write for our book L-36 on "Modern Furnace Building."

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

The Rugged Register

48-Hour Test Before Shipment

Because the VENTURI METER TUBE affords a high differential pressure at the inlet and throat it permits the use of an unusually rugged registering device, which also indicates the momentary rate of flow on a 12-inch dial and records the rate of flow on a circular chart.

VENTURI METER

Registers are, however, none the less accurate because they are rugged. They respond instantly to minute changes in the rate of flow and operate with a high degree of accuracy. This is because the readings from each device are tested before shipment by comparing them with the indications of a Single Tube Manometer. The Register also undergoes a hydrostatic pressure test of 300lbs. per square inch for 24 hours. Minor faults are corrected by experienced workmen and defective parts are replaced. The entire test covers a period of 48 hours.

Literature describing the VENTURI for measuring hot or cold water, sewage, brine, chemical solution, oil, gas, air or steam, will be sent on request.

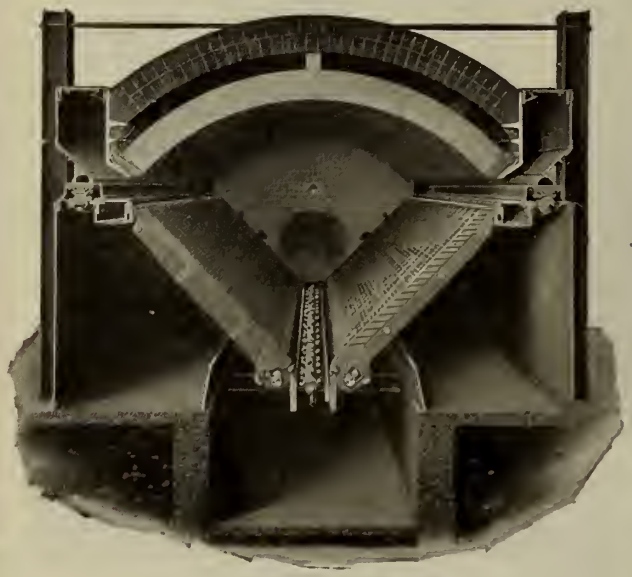
MURPHY AUTOMATIC FURNACES



Spending to Save

To-day you are vitally interested in reducing production costs. Is your power plant one of the many using hand-firing methods for boilers from 50 H.P. up to 300 or 400 H.P.? If so, you have an opportunity you cannot afford to overlook.

Investigate Murphy Automatic Furnaces and you will learn how thousands of satisfied users all over the country have made a saving of 15 to 30 per cent. on their coal bill—at the same time eliminating black smoke.

Spending money now to save money by reduced costs is not extravagance—it is sound, common sense.

Murphy Furnaces can be installed under any type of boiler from 50 H.P. up. Ask us to send you our Catalog HM-3.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalogue H R-3

Feed Regulation Planned Scientifically

Every boiler plant presents its own problem in boiler feeding. To meet specific operating characteristics with assured efficiency requires careful study of the conditions on hand before the proper automatic feed regulation can be applied.

COPES BOILER FEED REGULATORS

Each Copes is designed for the specific conditions governing the boiler—the control valve is neither too large nor too small. This insures maximum efficiency. Finally, the guiding force of the Copes is great in proportion to the internal resistance of the regulator, so as to insure smooth and continuous opening of the regulating valve and not a "step by step" motion.

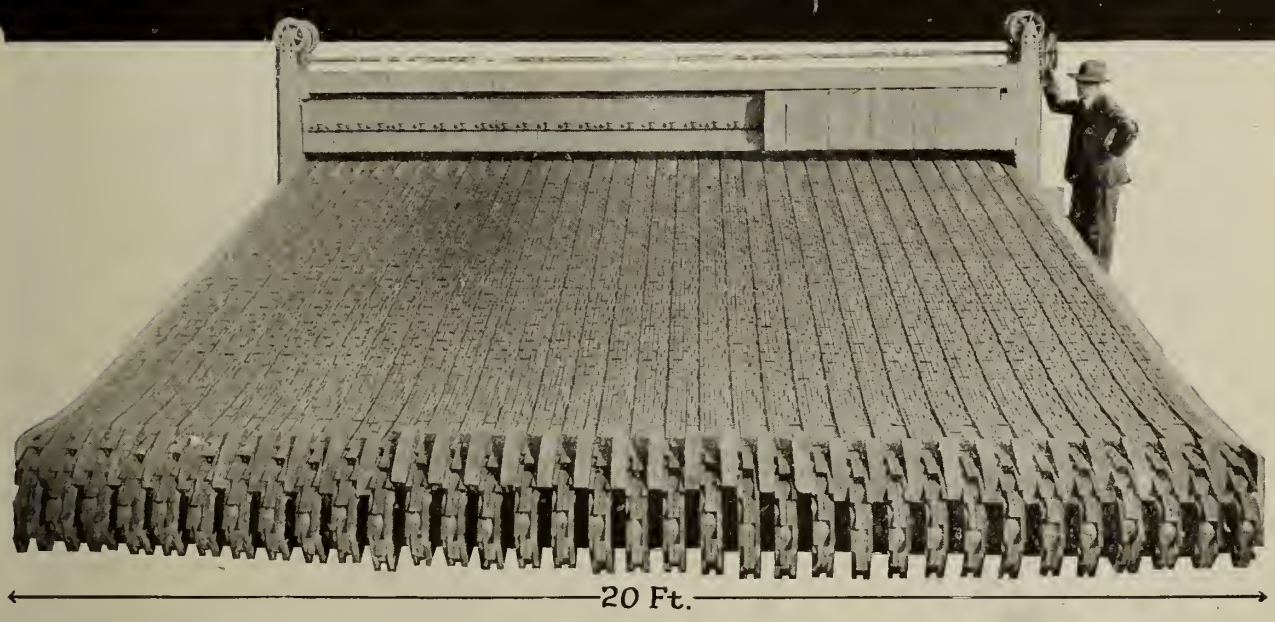
Largest Conveyor Feed Stoker Ever Built!



Pictured above is a 1200 H. P. STOWE STOKER—the largest single unit ever built on the conveyor feed principle. This stoker was designed to develop 300% of rating, and is now installed in the plant of the Central Illinois Light Co., Peoria, Ill., where it is giving excellent service.

You can get a single STOWE STOKER in sizes up to 1500 H. P. Think of being able to supply your 1500 H. P. Boiler with a forced-draft, conveyor-feed stoker in *one* large unit!

It means doing away entirely with the high maintenance of a center wall, which fills up furnace space and necessitates two stokers to a boiler.

The STOWE STOKER is a *forced-draft* type whose fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit. It is the last word in massive, durable and efficient construction.

When one considers first, the many striking features and advantages of the STOWE STOKER, and then, the marked simplicity of this mechanism, the realization comes that here is a truly great *achievement* in mechanical equipment design. Better write for the details.

We also manufacture The L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

The Bundy Oil Separator

SEPARATORS!

Why most engineers choose the—

BUNDY for Oil

and the

STRATTON for Water

The New Stratton Separator.

HE BUNDY Oil Separator is the **only** type that actually meets in practice the **three** vital requirements of an oil Separator.

1 — It insures maximum removal of oil from steam.
2 — It prevents steam from again picking up oil.
3 — Its separating efficiency is always maintained because it is easily cleaned.

The STRATTON Separator is of the centrifugal type. It thoroughly eliminates moisture without adding back pressure. Well known among engineers for its simplicity, large receiver capacity and high efficiency.

Stoker

Five Months of Steady Overloads—

Boilers in this plant were kept on line continuously for five months at 150% to 250% of rating. Name on request.

Three Months Continuously—Peak Loads at 340%

Such is the operating record of this "A-C." equipped plant. Name furnished on request.

Three Months of Continuous High Capacity

Boilers were kept on line continuously for over three months. Loads varied from 75 per cent. of boiler rating to 250 per cent. Name furnished if requested.

Service that Costs Less Per Year

Most plant owners and operators know that mechanical stokers are to-day a necessity from the standpoint of economy. Of course the stoker that gives lowest cost service is the stoker these power users want.

An investigation of the operating records of Jones equipped plants will convince them that Jones Stokers *do* give lowest cost service;

—that when the immense saving of these stokers is considered, first cost *is* lower.

—that because of their rugged simplicity—unequalled by any other multiple retort stoker—maintenance costs *are* lower.

—that their ability to meet high peak loads and heavy overloads, and maintain overloads constantly—confirmed by the plant records opposite—*does* mean still greater saving.

—that the saving of labor because of the ease of manipulation *is* greater.

—that the under-feed principle, as enhanced by improvements and refinements in Jones design, *does* mean greater economy in burning Canadian coals.

Jones Stokers are made in two types: Jones "AC" (Automatic-cleaning) Stoker for highest-duty requirements, and Jones "Standard" Stokers for a wide range of service.

Jones engineers will investigate your plant conditions and advise the type best suited to your own plant conditions.

JONES STOKERS are made in Canada by Canadian and sold for Canadian money. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized, and the new organization makes available for Canadian power users the resources and engineering resources of the Under-Feed Stoker Co. of America.

G. & McC. Co. Vertical Simplex Boiler Feed PUMPS

Modern Boiler Room Requirements

frequently necessitate the installation of pumps which differ materially from the ordinary Horizontal Boiler Feed Pumps. These special requirements include large Capacity, the ability to handle water at high temperatures, the necessity of operating against high pressures, and when used in connection with Water Tube Boilers, Pumps are required to give a regular, steady, slow feed and at the same time be ready to answer instantly to sudden demands for extra duty during periods of heavy load.

The Vertical Simplex Boiler Feed Pump fulfills these Requirements.

G. & McC. Co. Engines, Boilers, Pumps, etc. in your Power plant mean efficiency and dependability.

Efficiency Tests of a 30,000 k. w. Turbine

The Power Plant of the Interborough Rapid Transit Company, New York, Contains Three of These Units. The Turbines are of the Curtis Impulse Type, Having Twenty Pressure Stages

By HERBERT B. REYNOLDS, New York, N. Y.

IN order to provide additional power capacity for the new subways constructed in New York City during the period from 1913 to 1921, and operated by the Interborough Rapid Transit Company, additional turbine units were installed in both the 59th Street power stations. The three 30,000-kw. Westinghouse cross-compound turbines which were completed in 1915 were among the new units installed at the 74th Street Power Station. The results of the tests upon these turbines were presented before the Society by H. G. Scott and W. S. Finlay, Jr., in 1916.

At the 59th Street Power Station, the installation of three 30,000-kw. General Electric turbines has been completed within the past year. Very complete tests have been conducted upon these added units, the results of which are set forth on the following pages.

Reviewing briefly the history of the developments at the 59th Street Power Station, it will be recalled that the original engine-room equipment consisted of nine 7500-kw. maximum-capacity Manhattan type Allis-Chalmers double angle compound engine units, and three Westinghouse 1250-kw. turbines, the latter driving 60-cycle generators which supplied 60-cycle current for subway lighting. The use of this current for lighting was subsequently discontinued and in its place 25-cycle current is now used which is taken from the main units. During 1909 and 1910, five low-pressure 7500-kw. maximum-capacity General Electric turbine units were added, taking exhaust steam from five of the engines at atmospheric pressure. A description of these units and a full report of the tests which were conducted on them are given in a paper presented by H. G. Scott and R. J. S. Pigott before the Society in 1910. The units most recently installed in the 59th Street Power Station are the three 30,000-kw. General Electric turbines mentioned above.

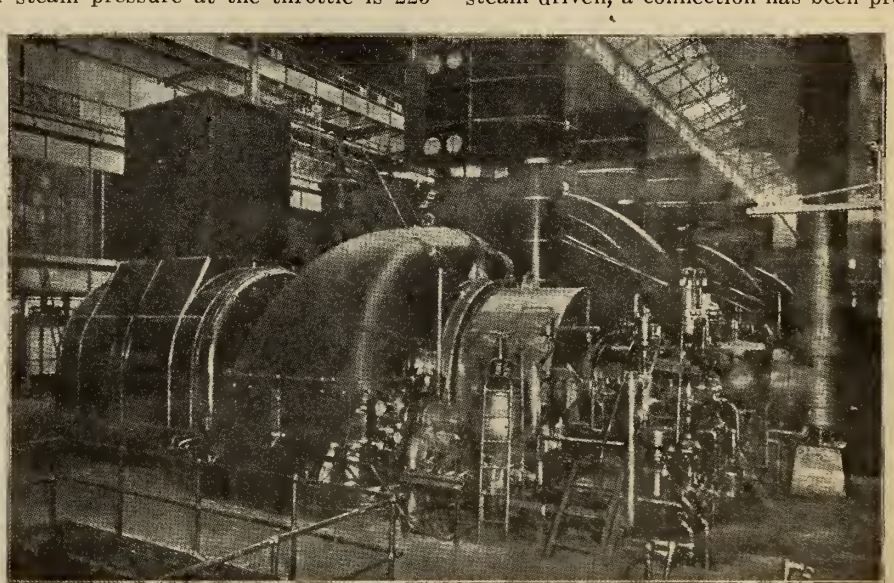
The Turbine Units

Two of the 30,000-kw. units, Nos. 7 and 8, were installed in the space formerly occupied by the three lighting units mentioned in the preceding paragraph, while the third turbine, unit No. 12, see Fig. 1, was installed at the western end of the station. The great concentration of power possible with modern turbines is strikingly shown by the space they require as compared with that for reciprocating engines. The maximum capacity of the engines which are visible in the figure is but 2625-kw. while that of the turbine in the foreground is 35,000-kw.

The general arrangement of unit No. 12, upon which the tests were conducted is shown in Fig. 2, The turbines are of the straight Curtis impulse type, having twenty pressure stages, each pressure stage consisting of one velocity stage. Fig. 1 is a close view of the governor end of the turbine and shows the auxiliary oil pump, etc. The normal steam pressure at the throttle is 225 lbs. per square inch abs. with a superheat of 150 degrees Fahr. exhausting into a vacuum of 29 inches Hg. referred to a 30 inch barometer at 58.1 degrees Fahr. The speed is 1500 r.p.m. In addition to the primary steam inlet, a secondary valve is provided which opens after the load reaches 24,000 kw. and which enables the turbine to carry a load of 35,000 kw. The generator is designed so that this load can be carried continuously.

Water sealed glands are used which obtain their water supply from the condensate discharge. A self-contained lubricating system is provided. The oil is circulated through the coolers and bearings by means of a pump driven from the turbine shaft. For starting up and emergency purposes a separate pump is provided which is driven by a small steam turbine, the speed of which is automatically controlled by the oil pressure. In addition to the cooling effect of the oil, the bearings are further cooled by the circulation of condensate through the water jackets.

As all auxiliaries in the station are steam driven, a connection has been pro-



One of the 30,000 K.W. Turbines installed in 1920.

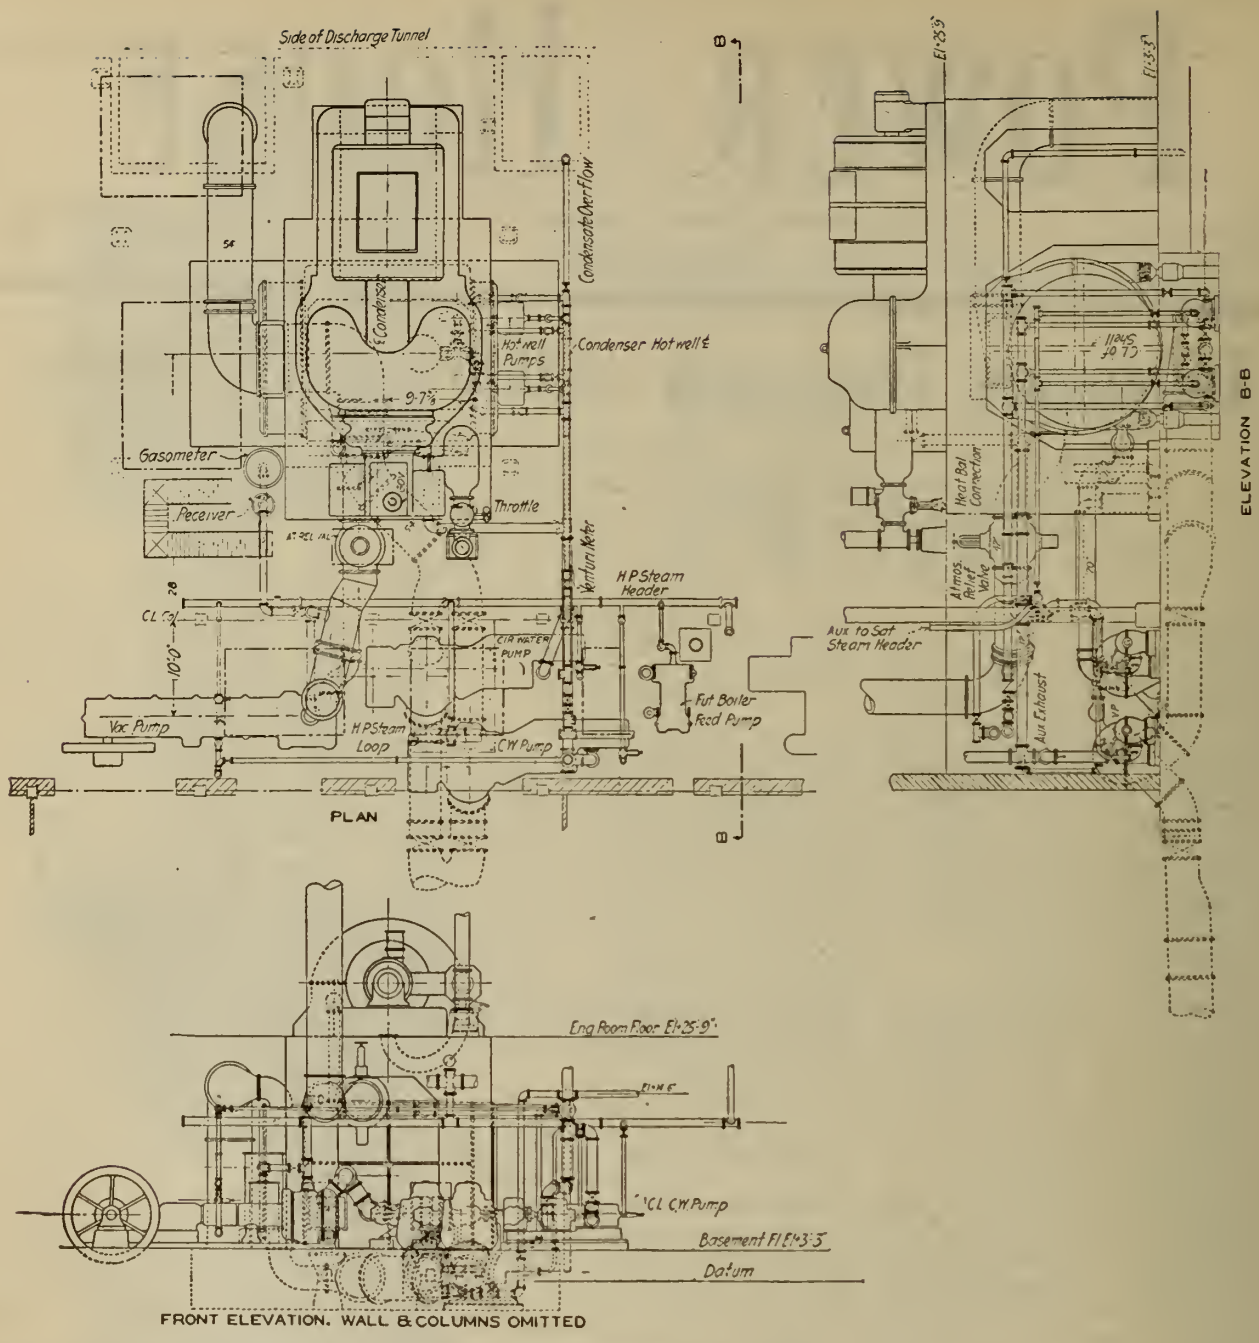

Fig. 2.—General Arrangement of Unit No 2

vided in the turbine through which any excess auxiliary steam may be injected. This connection is at the 16th stage of the turbine.

The generators are three-phase, star-connected, generating 25 cycle current at 11,000 volts. Excitation current is furnished at 250 volts. The generators are cooled by a circulation of air maintained by a fan which forms an integral part of the generator. The air is drawn from the turbine room basement and discharged from the top of the generator into the turbine room through a short stack which may be seen in Fig. 1.

Condensors and Auxiliaries

The condensing equipment for each unit consists of one single shell two-pass Worthington condensor, two Worthington centrifugal circulating pumps each driven through reduction gears by Kerr turbines, two Worthington centrifugal condensate pumps each driven by a General Electric turbine, one Laidlaw-Dunn-Gordon dry vacuum pump. The general arrangement of the condensing equipment is shown in Fig. 2.

Each condensor contains 50,000 sq. ft. of tube surface made up of 1,076 tubes 18 ft. long, 1 in. outside diameter and of No. 18 B.W.G. thickness. The condensor is of the two pass type, the water entering the bottom and passing out from the top. As the condensors are mounted on springs, rubber expansion joints are inserted in the circulating water lines.

Each circulating water pump is capable of delivering 30,000 gal. of water per min. against a total head of 37 feet. The turbines which drive these pumps operate at 3950 r. p. m. This speed is reduced to 395 r. p. m. through Kerr reduction gears. The impellers are made of bronze and are of the enclosed or shrouded design. Each condensate pump is capable of delivering 950 gal. per minute against a head of 60 feet. The turbine and pump both operate at a speed of 1500 r.p.m. The dry vacuum pumps are of the single rolling mill frame two-stage rotative type with poppet valve steam cylinder and two-stage water-jacketed vacuum cylinder.

Foundations

Two of the units No. 7 and 8 were installed on the foundations which formerly carried the three 1250 kw. 60-cycle lighting units mentioned earlier. However it was necessary to alter these foundations to some extent in order to receive the new turbines. The third turbine No. 12, was installed on new structural steel foundations encased in concrete.

As no expansion joint was provided

between the turbine and condensor, it was necessary to mount the condensor on spring supports so as to take care of expansion and contraction. These spring supports are shown in Fig. 3.

In order to facilitate the setting of these springs and also provide a means of detecting and adjusting for any fatigue which might occur in them, hyraulic jacks were incorporated in the condenser supports as shown of the turbine outlet and the face of the condenser inlet. The load on each of the four supports was then determined by noting the oil pressure on the jacks. It was decided that with the condenser empty and cold, the ownward pull on the turbine should not be less than approximately 17 tons. The distance that the joint between turbine and condensor would have to be pulled in order to give this load was estimated sure required to just raise the lock-nuts. Every few months the load carried by the springs will be determined in this manner and compared with the load which existed when the condenser was first bolted to the turbine. Any fatigue which may develop in the springs will be compensated for by screwing the lock nuts down.

It was found that the minimum condenser load carried by the turbine with

in Fig. 3 As the procedure followed in setting these springs may be of general interest a brief description will be given. After the erection of the condenser and circulating water pipe had been completed, with the exception of making the joint between the condenser and turbine, the condenser was raised while empty, by means of jacks, leaving 3/8 inches clearance between the face from the modulus of elasticity of the turbine and condenser metal. The condenser was then raised to within the predetermined distance of the turbine outlet, which was found to be .231 in. after which the lock nuts on the jacks were screwed home and the condenser bolted to the turbine. The load on the springs was then determined with the condenser still empty by noting the pres- the condenser shell empty was approximately 17 tons, which checked with the established minimum. As the water required to fill the condenser amounts to approximately 60 tons, the load on the turbine increases to 77 tons when the circulating water pumps are started. However as the result of a slight expansion of the condenser which takes place when it is warmed up, the springs

[3] Including rheostat loss.

[4] Tests Nos. 26, 27, 28 and 29 made with operating governor adjusted to limit maximum loads to the values shown in the second column.

[5] Test No. 16 made with secondary valve out of service.

[6] Test No. 38 made without load on generator, with generator field current adjusted to give normal voltage on open circuit.

[7] Test No. 39 made without load on generator, generator field not excited

are compressed and a small part of this load is transferred to the supports, reducing the load on the turbine to approximately 70 tons under operating conditions. Immediately after shutting down and while the condenser is still warm but drained, the load on the turbine is reduced to 10 tons. It will thus be seen that the condenser load on the turbine varied from ten to 17 tons. The total weight of the ocndensor varies from 180 to 240 tons.

Turbine Tests

The equipment used for conducting the turbine tests consisted of two large water weighing scales for measuring the steam consumption, three single phase rotating standard watt-hour meters for measuring the output, and all the necessary thermometers, gauges and mercury columns for determining temperatures, pressures and vacua as recorded in this report.

The water weighing scales had a capacity of 25,000 lbs. each. These scales were very carefully calibrated several times throughout the tests by standard test weights and the total steam consumption corrected accordingly. The rotating standard watt-hour meters which were used for measuring output were calibrated before and after the tests by the Electric Testing Laboratories, New York City. It is believed that both the input and output were measured within an accuracy of .25 per cent. All thermometers and gauges were also calibrated in the usual manner. The specific gravity of the mercury used in the vacuum columns was determined and corrections made accordingly. The readings obtained from the mercury columns were further corrected for meniscus, temperature, and barometer reading. The barometer reading was obtained from the local U.S. Weather Bureau.

Most of the tests were of three hours duration. With the exception of a few special tests, the turbine was operated under normal conditions so far as type of load was concerned. The load was

the remote governor control system provided for that purpose. This method of controlling the load subjected the turbine to the full swings of the railroad load.

Table 1 gives the numerical results of the turbine tests, while the performance is shown graphically in Figs. 4, 5 and 6. Fig. 4 gives the total steam consumption and water rate of the unit, while Fig. 5 gives the thermal and Rankine-cycle efficiency. From these curves it will be seen that the lowest water rate obtained while operating under normal conditions was 11.03 lbs. per kw. hr., while the highest Rankine and thermal efficiencies obtained were 75.5 per cent and 25.0 per cent., respectively. As stated above, all tests with the exception of seven were conducted under operating conditions.

In order to determine the effect of the swinging load on steam consumption, four tests were conducted with the governor blocked so that the unit operated under a steady load. These tests are shown in Fig. 4 and 5 by the small square It will be seen that there is no improvement in the efficiency under the steady load conditions at the loads selected for these tests. When the turbine is operated under normal conditions and carrying loads from 22,000 kw. to 25,000 kw. the secondary valve is continually opening and closing, which no doubt reduces the economy somewhat. If a steady load test had been conducted within this range the points would probably have fallen on the dotted curve. The test shown by the small triangle in Figs. 4 and 5 was run with the secondary or overload valve closed and out of commission, while the load was adjusted so that the primary valve was wide open. As was to be expected, the lowest water rate was obtained while operating in this manner. Since the completion of these tests the governor cams have been modified so that the opening of the secondary valve is delayed.

This may improve the economy to some extent near and at the best load point, however no tests have been conducted to determine just how much improvement has been accomplished.

Test No. 38 was run without any load on the generator, but with the field excited to give normal voltage on open circuit. The actual steam consumption per hour during this test amounted to 17,850 lbs. Another no load test was conducer, but without any excitation, during which the actual steam consumption amounted to 16,090 lbs. per hour. No attempt was made to correct the steam consumption during these two no-load tests, due to the vacuum being low and outside of the range of the correcting curves.

Fig. 6 shows the variation of steam pressure with the load at various points throughout the turbine. In order to correct the steam consumption to the standard conditions, the curves given in Fig. 7 were used.

Water-rate Factor

In order to make an absolute and numerical comparison of the flatness of water rate curves for different turbines, an expression has been used which is termed the water rate factor. Expressed mathematically,

$$F = \frac{MW}{C}$$

in which F = water-rate factor; M = minimum water rate obtained; W = mean load between one-half rated load and maximum load, which is the usual operating range; and C = average total steam consumption per hour covering the range between one-half rated and maximum load.

(Continued on page 27)

The Craftsmen's First Canadian Convention

Excellently planned, and well carried out, this convention has set a high mark for other engineering societies to follow. The exhibition of power plant appliances was a very big feature.

THE City of Toronto was the scene of great activity in so far as engineering circles went, during the week of August 1st, when the Universal Craftsmens Council of Engineers held their first Canadian Convention. Though the first time the Convention has been held in Canada, the order has held many in the United States, where the membership and number of councils are very large.

Probably more men in charge of large stationary engineering plants were in the city of Toronto during that week than at any previous time in the City's history. From the first thing Tuesday morning when the delegates and visitors were welcomed to the city by the Mayor, things went with a swing, and the King Edward Hotel was full of bustle and cheer as the delegates and their companions circulated from meeting place to exhibition hall, and stopped to chat to old and new friends in the course of their journeyings.

The Exhibition

Everybody who found their way into the Pompeian Room, whether from idle curiosity, or a genuine wish to see and learn, which was the motive of the majority, was enthusiastic over the display that was put on there by the various firms exhibiting. There was very little in the way of accessories and equipment for plants that was not in evidence in that room. The arrangements of the booths that had been carried out by the Craftsmens Committee was such as to give general satisfaction to all those who had taken space. On entering the room a fairly comprehensive view of there was ample room in the aisles bethe whole thing could be obtained, and tween the booths to walk round and view the various exhibits, and to stay awhile where one was most interested.

The firms holding space were the following:—Beldams Canadian Asbestos Co., showing a full line of packing, steam and hydraulic. Crouse Hinds Co. of Canada Ltd., Electrical fittings and conduits. James Morrison Brass Mfg. Co., Steam gauages, injectors, valves. Chapman Double Ball Bearing Co., Working model of ball bearing. Canadian Johns Manville., Asbestos products. Kirby & Co., Packing etc. Demco Machine Tool Co., Patent Hotwater Mixing valve. Refinite Co. of Canada., Water softening apparatus. Superheater Co. of Canada., Superheaters. S. K. F. Ball Co., Working models showing ball bearings. Valve Engineering Co., Valve specialities. Otis Elevator Co., Elevators. Moving pictures illustrating productive methods. Canadian Sirocco Co., Fans and Blowers. Dominion Flow Meters and Co., Recorders. Everlasting Valve Co., Everlasting Blow Off and other valves. Dearborn Drug & Chemical Co., Boiler Water Treatment. Jenkins Valve Co., Various valves. Underfeed Stoker Co. of Canada., Model of underfeed stoker and Coles Regulator. C. A. Dunham Co., Heating appliances, radiater traps. Canadian Powers Regulator Co., Patent thermostats for temperature regulation. J. H. Wenting, Mason Contractor, Fire brick, etc. Crane Ltd., Steam and Water Valves, Pipe Fittings, etc. Allen General Supplies, Copes Boiler Feed Regulator, and power plant supplies. William C. Wilson, Packing, Boiler Cleaner etc. Darling Bros., Heating specialities, pumps etc. W. R. Sexton Boiler Setting Co., Non-pareil grate bars, boiler setting. Taylor Instrument Co., Full line of thermometers, pyrometers, recorders. Lumkenheimer Valve Co., Valves. Garlocq Packing Co., Packing. McColl Bros., Lubricants. Hollow Centre Packing Co., Oils and Lubricants. Black Donald Graphite Co., Graphite. W. H. Cunningham & Hill Ltd. Canadian Blower & Forge Co., Fans and Blowers. Pierce Fuse & Devoe Switch., Patent Fuses and switches. Henry Engineering Co., Vesta Storage Battery. Taylor & Arnold Co., Recorders. Home Rubber Co., Packings and rubber goods. Keystone Grease Co., Lubricating Grease.

The Entertainments

The programme was carried out exactly as arranged by the Committee, and the visitors were certainly shown all Toronto had to offer. On Wednesday evening about 55 automobiles were required to convey the delegates and their ladies on a trip around the city. This was conducted under the auspices of the chief of police, who did away with all traffic difficulties, and handled the affair in a way that brought much praise from those who enjoyed the benefit of this care. The drive covered all the most interesting spots in and around the city, and was destined to give the American visitors food for reflection, as by the remarks passed it evidently did. It was amusing to note the surprise evinced by many of those coming from the middle western and southern states, who had never been in Canada before at actually finding such a city. Many of them were so much impressed that they expressed a wish to remain here altogether, although we think they might revise that opinion if they were to visit here in one of our old fashioned winters.

The drive was followed by a most enjoyable dance at the Sunnyside Pavilion, which lasted well on till midnight, and was a very fitting close to an enjoyable day.

The big event as far as the menfolk were concerned, was the picnic at the Island on the Thursday afternoon. Everybody got together for this event, and the sun, who had been rather coy for the first day or two, came out in his full regalia to see that the thing went right. Centre Island proved another eye opener to the American visitors, and we believe there will be a vast amount of good advertising accruing to Toronto in particular and Canada in general as the result of this convention.

Arrived at the Island, the programme of sports was got under weigh without any delay, and the resulting races were enjoyed by all present. The following races were run off:—

Tot's Race—Won by D. Allman, Ida Otis second.

Girl's race, under 8—Won by M. Rumley, A. Chalmers second.

Boys Race, under 8—Won by D. Allman, J. Serton second.

Girl's Race, under 12—Won by Evelyn Otis, Elsie Ottis second.

Boy's Race,. under 12 — Won by A Auchterlonie, H. McLaren second.

Mens 100 yards—Won by E. Worthington, H. Thompson second.

Ladies 50 yards—Won by Miss Woodman, Miss Marden second.

Ladies Heavyweight, 50 yds.—Won by Mrs. Aucherlonie, Mrs. Buckley second.

Mens Heavyweight, 75 yds.—Won by A. Auchterlonie, H. Parker, second.

Cat Race, Lady & Gentleman, 50 yds. —Won by E. Worthington and Miss Woodman.

Members of Canada Council, 45 and over, 75 yards—Won by J. Parkes.

Past Grand Chief's Race, 50 yards—Won by H. E. Terry.

Ladies Committee, 50 yards—Won by Mrs. Allman, Mrs. Potter second.

The big event was the baseball match between the Craftsmen and the exhibitors, which was productive of heavy hitting, wonderful base running, and weird umpiring. During the five innings which it lasted, we can truthfully say that there was not a dull moment and the yells that went up from the side lines would have put a whole tribe of Comanches to shame. The gentlemen who were keeping the score for either side added as many runs at the end of each inning as they thought their team required and through their efforts the game resulted in a tie. As a matter of fact the exhibitors were getting runs that fast at one stage of the game that an adding machine would have been necessary to count them all. However, all things must end, even such a ball game, and the contestants lined up for the official photograph, which included all present. This photograph was on a scale which makes it difficult to reproduce in our pages, as the figures would appear too

small when reduced to the dimensions required. However it was an excellent photograph.

After the photograph supper was served, and those who felt like it drifted away to the dancing pavilion and finished up the evening in that fascinating pursuit. The others rested in the cool glades of Centre Island till time to return to the city bed.

The final entertainment was on the Friday night, when nearly 400 delegates, visitors, exhibitors sat down to a banquet in the Tabard room of the King Edward Hotel. An excellent repast was provided, following which there was an entertainment interspersed with speeches. The entertainment was in the hands of Mr. Chas. Leslie, Miss Vera McLean and Mr. Jimmie Reid, and their efforts were very well received, they being repeatedly recalled after each number. The speeches were brief, and to the point, and every speaker expressed the pleasure he had received in attending the convention, while Mr. Cudbird and his committee came in for unstinted praise. The speech of the evening was delivered by Mrs. Aldridge, President of the Ladies Council, in replying to the toast of the Ladies Council. Mrs. Aldridge possesses a full clear voice, which she uses admirably, and a command of vigorous clear cut English which put to shame most of the male speakers.

Conclusion

It must not be imagined that the convention did nothing but have a good time. The members of the local Councils and the delegates from the various councils in the States who attended were in session a goodly portion of the time. The result of the discussion re the next year's convention was that Cleveland will have the honor.

Mr. L. J. Cudbird, to whom must go the larger share of the credit for the success of the event, was honored by election to the Grand Lodge of the Council. He was also presented with a very handsome club bag for his efforts by the Grand Lodge. Mr. Terry, the secretary-treasurer who also had a large part of the burden, came in for special mention. The members of the committee as on the result of their efforts, which brought about such a smooth running and well managed convention.

The firms that had exhibitions in connection with the convention were all very highly pleased at the treatment they received, and at the number of visitors that came to their booth. They were kept busy in between the business sessions showing and explaining their goods to the interested crowds that came around.

There will without doubt be a great deal of benefit accruing to those who exhibited, even if it cannot be directly traced We must say for our part that quite a number of American visitors took away copies of Power House, and were very much interested to find that Canada had a technical publishing house of its own.

It is one of the greatest benefits of these Conventions and exhibitions that they tend to break down the wall of ignorance which stands between us and so many of our Southern neighbors. While the average Canadian knows pretty much about the States, the ideas entertained by some citizens of the U. S. about Canada can only be dispelled by a personal visit, and it is just such conventions as this that gives them the chance to widen their minds.

As we said in our editorial last week, the Craftsmans Council have done a service to the engineering profession, their city and their country, by having the courage to enter into such a large undertaking and carrying it to a succesful conclusion.

EFFICIENCY TESTS OF A 30,000 K. W. TURBINE

(Continued from page 25)

Using the curves given in Fig. 4, substitutions may be made as follows:

$$F = \frac{11.03 \times 25{,}000}{280{,}100} = 0.985$$

This factor could be expressed by using the ratio between the minimum water rate and the average water rate over the range selected. However, the factor obtained in this manner would not take into account the fact that it is more desirable to obtain flatness in water-rate curves at the high loads than it is at the low loads. By using the total steam consumption as indicated in the expression given above, a fairer comparison is obtained.

Condenser and Auxiliary Tests

Tests were conducted on the condensers and auxiliaries. A summary of the condenser and dry-vacuum pump tests, which were run simultaneously, is given in Table 2, while the relation between the load and vacuum is shown graphically in Fig. 8 In examining the results of these tests and comparing them with the vacuum obtained during the turbine tests, it should be kept in mind that the temperature of the circulating water during the condenser tests, which were run during the summer, was very high, varying from 75.1 deg. fahr. to 78.2 deg. fahr. The methods used in determining the quantities given in Table 2 need no description, with the possible exception of the measurement of the air discharged from the dry-vacuum pump and the steam consumption. The air was measured by a gasometer connected to the discharge of the pump. The steam consumption was determined by condensing the exhaust steam in a small test condenser, after which it was weighed in the usual manner.

Table 3 gives the results of the tests on the circulating-water pump. It will be seen that two tests were conducted on these pumps, one being an economy test while the other was a maximum-capacity test. Only one of the two pumps was running in either test. During the economy test the discharge valve was adjusted to give the normal operating head which exists when two pumps are running, while in the capacity test it was left wide open. The quantity of water pumped was computed by the heat-balance method, which involved the measurement of the main turbine condensate, its temperature, the temperature of the circulating water in and out, the steam conditions at the main-turbine throttle, load on main unit, etc. The steam consumption of the turbine driving the pump was determined by means of the small test condenser mentioned above. The results of the condensate pump test are given in Table 4.

HANOVER LODGE C. A. S. E.

The Hanover Lodge C.A.S.E., one of the youngest lodges in the organization, held its second annual picnic on Monday August 1st civic holiday. A good muster turned out for the occasion, and the Federal member for Hanover Mr. R. J. Ball, gave an interesting address on the value of education for the engineer, and his employer. In this connection it is iteresting to note that the manufacturers of Hanover have given the lodge the use of a building to hold their regular meetings in.

THE SMALLEST PUMP IN THE WORLD

What is the smallest pump in the world? This is a difficult question to answer, but it would be equally difficult to light upon any pump at once smaller and simpler than that recently devised by a British Engineer. It consists of a piece of rubber tubing bent into a hoop, with a wooden frame outside the loop and a circular cam inside. By placing the cam out of centre and revolving it the rubber tube is squeezed in a rotary direction, giving a kind of "milking" action which will force liquid through it. One end of the tube then becomes the suction pipe and the other te delivery pipe of a very neat and efficient form of pump. The inventor after having made a pump out of a serviette ring and piece of rubber tubing, has take out a patent for a regular engineering mechanism on the same principle. He proposes to use a flexible rubber or leather band suitably water-sealed on its width, in place of the tubing, and cast iron or gun metal casing with suction and delivery branches. This type of pump, it should be noted, has no valve and will therefore be suited for use in cases where pump valves are apt to give trouble.

The handy wiring tables and illumination data just issued by the Ceo. Cutter Works of the Westinghouse Electric & Mfg. Company at South Bend, Ind., contains a considerable amount of data which is of interest to anyone connected with the problems of wiring and lighting offices, factories, etc. Tables of foot candle intensities recommended for different classes of service, are included in this booklet, and an interesting discussion of lighting installations is made. Several new devices manufactured by the Westinghouse Company are shown in this booklet.

Description of New Type of Water Turbine

This Outline of a New Type of Turbine Was Given at the Sym posium on Hydro-Electric Development Held in January Last Under the Auspices of the Engineers Club of Philadlephia

By L. F. Moody

IT seems, from a review of papers read before the Symposium on Hydro-electric Development and Distribution, held in January under the auspices of the Engineers' Club of Philadelphia and the principal engineering societies of America, that the forecast made by Mr. Anderson, just a year ago, at the Institution of Mechanical Engineers, was quite true, and that the water turbine, having passed through a stage of rather complex design, is reverting to a much more simple axial flow form, and that this tendency towards simplicity does not involve any sacrifice of adaptability.

Within comparatively recent times it was considered necessary, in order to obtain the speed required for driving electric generators, to use several turbine runners on one shaft, specially in cases where large powers had to be developed with only moderate heads. The use of multiple runners—as many as eight have been used in one turbine—naturally led to complication in the vane mechanism, while the tortuous water passages involved by the arrangement were a serious handicap to efficiency. Careful investigation of the conditions has however indicated that this complication is unnecessary, and Mr. L. F. Moody gave an outline, at the Symposium just mentioned, of a new type of turbine possessing even greater simplicity than those of a generation ago, but nevertheless capable of adaptation to the requirements of modern hydro-electric plants.

The evolution of this new type of turbine has come about through the mathematical study of the conditions of water flow, and Mr. Moody gave an analysis of this study in his paper. With the forms of mixed flow turbine which have recently been in vogue, that is to say, turbines with runners in which the direction of flow of the water was changed several times in the course of its passage from the inlet to the outlet, it has been practically impossible to employ mathematical principles in designing the passages, and the theories which have been put forward have been of little assistance to the engineers. Mr. Moody, however, started by setting down the fundamental requirements of a turbine without reference to any indivldual machine. These requirements are given below in his own words:—

"(1) A casing in which the water can approach the runner symmetrically with respect to the axis on all sides, without any obstructions or enforced abrupt changes of flow which would introduce eddies or unsymmetrical distribution of velocity. The spiral or volute casing meets these conditions, and in most cases is the most satisfactory form of intake. On account of the increase in the velocity of the water from a low value in the intake to a high value where it passes through the runner, the water passage must contract radially as it approaches the runner, and must subsequently expand again. The approach of the water to the runner therefore involves a radial component of flow toward the axis and by so-called speed vanes of stay vanes, and by the movable guide vanes or gates the water is given increasing whirl or rotationa components of motion about the axis as it nears the runner. After leaving the guide vanes the water continues to increase in velocity of whirl due to its closer approach to the axis, and at the same time it turns in the meridian plane and takes the axial direction either just before, during, or just after its passage through the runner.

"(2) A wide transition space is provided between guide vanes and wheel vanes and in this space the water can come together in a continuous whirling mass before entering the runner. In a high-specific-speed turbine the water continues to contain whirl components of motion, but of somewhat reduced amount, after leaving the runner, even when the turbine is operating at its point of best efficiency.

"(3) After leaving the runner the water continues to flow as a whirling, axially advancing stream in a draught tube having a straight axis coincident with that of the turbine, and conical or flaring walls, this form of tube continuing, if what the writer believes to be the best practice is followed, until the velocity head has been reduced to so low a value that no serious disturbance in the symmetry of the flow into other directions or by finally discharging the water."

The specific speed referred to in the second paragraph above is, of course, the basis of comparison for turbine runners, or the number of revolutions per minute which a similar wheel would have to run at, at maximum efficiency, to develop 1 horse-power with a head of one ft. to 20 ft., whie the specific speeds of tion turbines range from about 20 to 100 inversely as the head varies from 750 ft. to 20 ft., while the specific speeds of Pelton impulse wheels lie between one and seven.

In looking forward to the future development of the turbine, Mr. Moody shows that theoretical considerations call for a conservative proportioning of the various velocities and angles of the turbine, and that there is no apparent means of greatly increasing specific speeds merely by using some new and radical proportion between the velocities. Efficiencies are already so high that no starting increase is possible. The prospect of further increases in specific speed therefore lies entirely in the use of higher velocity

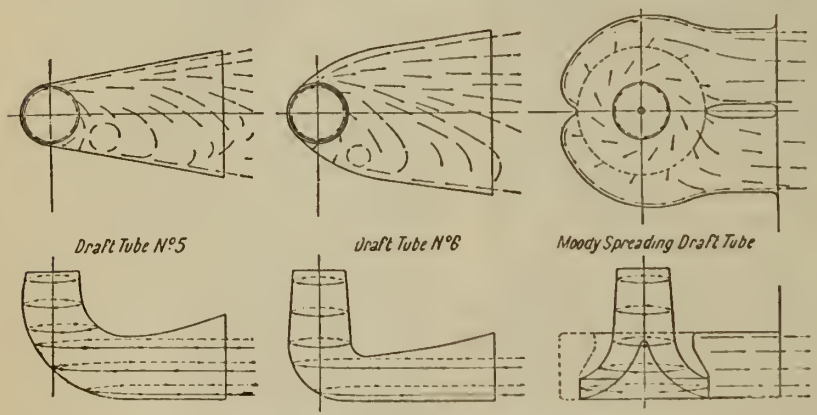

Fig. 1.—Alternative Forms of Draught Tube

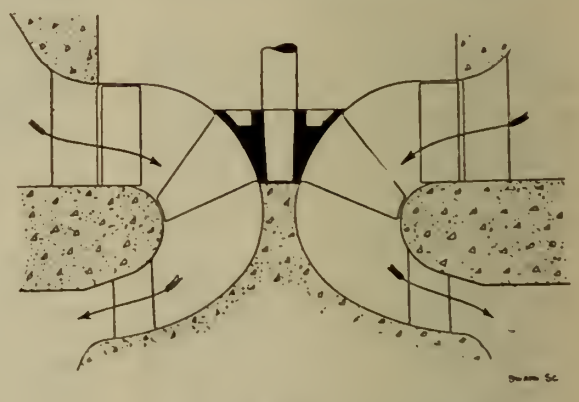

Fig. 2.—A New Type of Turbine

heads in comparison with the head on the plant, and an avoidance of serious impairment of the efficiency, by giving attention to the securing of low coefficients of loss in the runner and draught tube, and by observing the relations between the velocities of outflow from the runner.

Reverting to the turbine which will meet the conditions laid down above, it may be viewed as a water passage having walls which are surfaces of revolution and containing a continuous body of water which is both whirling and progressing with radial and axial velocity components, in which is placed a runner which develops torque by reducing, but not necessarily destroying, the whirl components of the flow. If a draught tube is used which is capable of regaining a considerable part of the energy due to the whirl components, as well as that due to the axial components of the velocity if discharge from the runner is reduced to a small fraction ly be secured, the "outflow loss" from the runner is reduced to a small fraction

sible to lose 17 per cent. of the total head with a design of draught tube which fails to regain any of the velocity. For low specific speeds such as 20, the axial component is less than 2 per cent. of the total head and the whirl component is entirely negligible. Therefore, for low specific speeds the design of the draught tube is not important from the viewpoint of efficiency.

A long, straight draught tube with a small angle of diffusion is probably the most efficient design, but for large units such a construction would involve costly excavation, and hence some form of curved tube must be adopted. Fig. 1 shows different types of draught tube designs. The losses caused by changes in the direction of flow are severe. The water leaving the runner is whirling in the same direction as the runner rotates, the centre of the vortex being the vertical axis of the draught tube. This vortex tends to remain in the same plane on account of its gyroscopic properties, and will not therefore follow the centre line of the curved type of tube. As in-

a similar machine with a curved tube. Photographs of a power plant where Moody draught tubes have been installeded show how smooth is the flow of the water in the tail-race as compared with the turbulent, frothy discharge from the curved draughts of the older units.

Reasoning on the same principles, Mr. Moody suggests the use of continuously curved inner and outer surfaces of revolution for the turbine water passages, thus avoiding all sudden changes of curvature. Fig. 2 shows, in outline, a turbine embodying these principles. The entrance passage merges into the runner space and the latter merges into the draught tube. The flow passes into the draught tube by continuous gradation, with gradual changes in the whirl about the turbine axis, and without sudden variations of the secondary whirl occurring in the meridian plane, i.e., the plane of the figure.

If a ring of vanes such as a runner is interposed in the revolving mass of

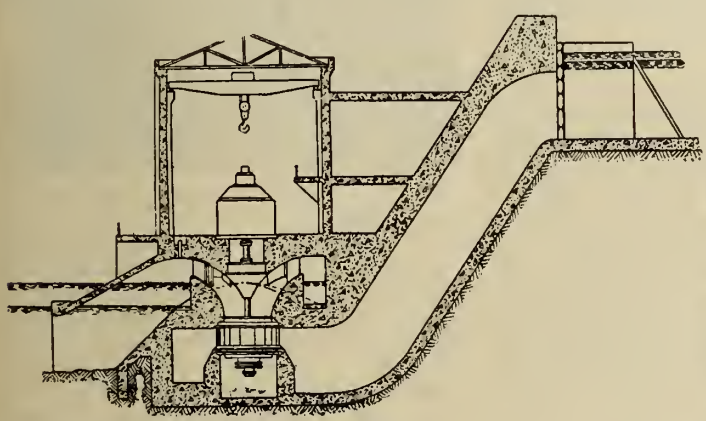

Fig. 4.—Suggested New Arrangement of Turbine

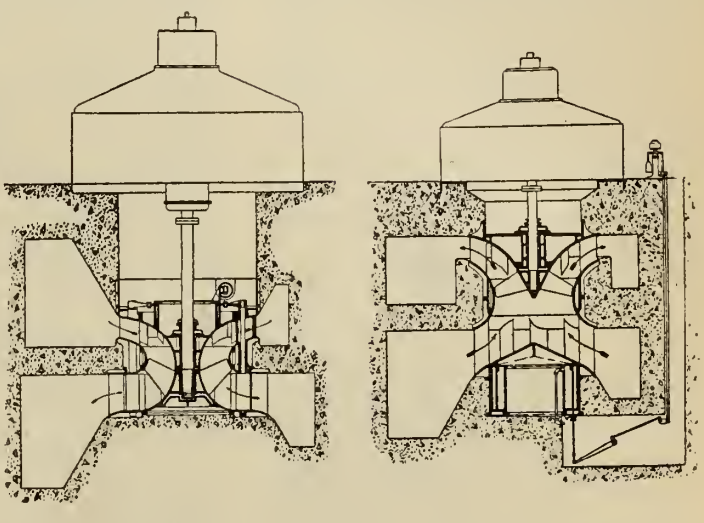

Figs. 5 and 6.—New Turbine with different types of control.

of that which enters into the usual text-book formulas.

The laws which govern a vortex can be applied to investigating the flow of water through such a turbine, and it follows that the velocity if whirl varies inversely as the radius. This fact introduces an important consideration in the design of the draught tube, as it enables the whirl velocity, at the discharge of the runner, to be gradually reduced and regained as presure head.

Dealing with this part of the subject, in another paper read before the Symposium, Mr. F. H. Rodgers said that for a specific speed of 80 the energy at the discharge of the runner to be regained in the draught tube amounts to 11 per cent. of the total available head for the axial velocity and six per cent. of the total head for the whirl velocity. The total energy to be regained in the draught tube is represented by the sum of these values. For high speed runners therefore draught tube design is of great importance, for no matter how efficient the runner may be in itself, for the case assumed above, it is pos-

dicated in the figure, with this type of tube serious eddies and whirls occur in the curved portion, so that at the discharge of the draught tube it is usually found that but a portion of the discharge area is effective. Water from the tail-race actually flows in the reverse direction back into part of the tube, thus causing serious eddy losses and high outflow losses in the other portion of the tube. The tube 6 shown in this figure is slightly better than tube 5, as the straight portion of the tube is longer and hence the whirl components are somewhat reduced before the water enters the curved portion of the tube.

In the case of the Moody spreading draught tube. The flow passes into the metrical about the axis of the turbine, and the whirl velocity is greatly reduced before the water is discharged into the surrounding chamber. The axial component of the flow is regained and most of the whirl component also saved. Laboratory tests have shown that a turbine equipped with one of these draught tubes possesses an efficiency higher by one per cent. than that of

water, the torque exerted on the vanes by the water is equal to

Where W is the weight of water, r1 and r2 the radii of entry and exit of the runner, respectively, and cu1 and cu2 the corresponding circumferential components of velocity. Fig. 3 shows the form of runner employed in this new type of high-speed turbine.

The natural outcome of adopting the high specific speeds associated with this class of turbine is an increase in the velocity head at the discharges. In order that the absolute pressure at the runner discharge may be kept at a value giving a margin above the point at which water will vaporize, and to provide the head necessary for the retardation of flow during quick gate closures, the sum of the static elevation of the runner above the tail water and the regained velocity head should not approach too closely to the barometric height, and preferably should not be more than 27ft.

In order to meet this requirement and yet permit the adoption of high specific

(Continued on page 31)

Amendments to the Ontario Engineers Act

A PERSON who desires to operate a stationary steam or gas plant of between 25 and 50 H. P., or to operate under a certificated engineer a stationary steam or gas plant of 50 H. P., or over, when the safety valves are set in such a manner that they cannot relieve the pressure at ten pounds or less, must hold a Fourth-class Certificate. (Application forms for this purpose will be supplied on request).

A candidate for Fourth-class Certificate shall be required,

(a) To be at least 19 years of age;

(b) To take an affidavit on a form supplied by the Board, showing that he has had the required six months' initial operating experience, including at least three months' operating experience in the boiler room;

(c) To satisfy the Board as to character and ability;

(d) To pay a fee of Three Dollars at the time application is made for examination. (This fee shall not be returned to the applicant should he fail to pass the examination);

(e) To answer the questions on the examination paper and secure at least sixty per cent of the marks.

Third-Class Certificate

A person who desires to operate a stationary steam or gas plant of between 50 and 200 H. P., or to operate a stationary steam or gas plant of over 200 H. P., under a certificated engineer, when the safety valves are set in such a manner that they cannot relieve the pressure at ten pounds or less, must hold a Third-class Certificate. (Application forms for this purpose will be supplied on request).

A candidate for Third-class Certificate shall be required:

(a) To be at least 21 years of age;

(b) To be a holder of a Fourth-class Ontario Certificate of the current year or its equivalent in H. P., from one of the other Provinces of the Dominion;

(c) To take an affidavit on a form supplied by the Board to the effect that he has had at least two years' experience operating in a stationary steam or gas plant, showing at least six months' experience in a boiler room and six months' experience in an engine or compresser room;

(d) To pay a fee of Five Dollars at the time of making application for examination. (This fee shall not be returned to the applicant should he fail to pass the examination);

(e) To answer the questions on the examination paper and secure at least sixty per cent of the marks.

Second-class Certificate

A person who desires to operate a stationary steam or gas plant between 200 and 600 H. P., or to operate a stationary steam or gas plant of 600 H. P. or over, under a certificated engineer, when the safety valves are set in such a manner that they cannot relieve the pressure at ten pounds or less, must hold a Second-class Certificate. (Application forms for this purpose will be supplied on request).

A candidate for Second-class Certificate shall be required:

(a) To be the holder of a Third-class Certificate of the current year or its equivalent in H. P. from one of the other Provinces of the Dominion;

(b) To take an affidavit on a form supplied by the Board, to the effect that he has served an apprenticeship of at least two years as a stationary engineer, erecting engineer, machinist, boiler maker or blacksmith, or has completed at least a two- year course in Science or Engineering in any University. To take an affidavit to the effect that, in addition to his apprenticeship or University Course, he has had three years' experience in the operation and charge of a steam or gas plant, including at least one year's experience in the boiler room and one year's experience in the engine or compressor room;

(c) To pay a fee of Seven Dollars at the time of making application for examination. (This fee shall not be returned to applicant should he fail to pass the examination):

(d) To answer the questions on the examination paper and secure at least sixty per cent of the marks.

A person who desires to operate any steam boiler and engine or steam boiler, working with the safety valve set in such a manner that it cannot relieve the pressure at twenty pounds or less, irrespective of horse power, when used for the purpose of operating steam shovels, steam locomotive cranes, steam derricks, steam hoists, steam drags, and all other similar apparatus used for hoisting and excavating purposes, must hold a Hoisting Engineer's Certificate from this Board.

First-Class Certificate

A person who desires to operate a stationary steam or gas plant of 600 H. P. or over, when the safety valves are set in such a manner that they cannot relieve the pressure at ten pounds or less, must hold a First-class Certificate issued upon examination by the Ontario Board, (Application forms for this purpose will be supplied upon request.

A candidate for First-class Certificate shall be required:

(a) To be the holder of a Second-class Certificate of the currant year or its equivalent in H. P. from one of the other Provinces of the Dominion:

(b) To take an affidavit on a form supplied by the Board, to the effect that he has served at least three years' apprenticeship as a stationary engineer, erecting engineer, machinist, boiler maker, or blacksmith, or has completed at least a three-year course in Science or Engineering in any University to take an affidavit to the effect that he has had at least seven years' experience, in addition to his apprenticeship or University Course, as Chief or Operating Engineer of plants of Two Hundred H. P. or over;

(c) To pay a fee of Ten Dollars at time of making application for examination. (This fee shall not be returned to the applicant should he fail to pass the examination:

(d) To answer the questions on the examination paper and secure at least seventy per cent of the marks.

Portable Engineers' Certificates

A person who desires to operate any steam boiler and engine or steam boiler, working with the safety valve set in such a manner that it cannot relieve the pressure at twenty pounds or less, irrespective of horse power, when used in the operation of steam road rollers, steam tractors, steam locomotives, steam waggons not using flash boilers, well drillers, portable saw-mills, and all other similar apparatus used in the operation of portable work, must hold a Portable Engineer's Certificate from this Board.

A person who desires to operate any steam boiler and engine or steam boiler, working with the safety valve set in such a manner that it cannot relieve the pressure at twenty pounds or less, irrespective of horse power when used in the operation of concrete mixers, drills, pumps, air compressors and heating systems temporarily intalled during construction work, must hold a Hoisting Engineer's certificate or Portable Engineer's Certificate from this Board.

A candidate for Hoisting or Portable Engineer's Certificate shall be required:

(a) To be at least 19 years of age;

(b) To take an affidavit on a form supplied by the Board to the effect that he has had at least fifteen months' operating experience in a steam plant, including three months' operating experience of a hoisting steam plant in the case of a Hoisting Engineer, and three months' experience in a portable steam plant in the case of a Portable Engineer:

(c) To satisfy the Board as to character and ability;

(d) To pay the fee of Five Dollars at the time application is made for examination: (This fee shall not be returned should the applicant fail to pass the examination):

(e) To answer the questions on the examination paper and secure at least sixty per cent of the marks.

NEW TYPE OF TURBINE

Continued from page 29

speeds, with corresponding outflow velocities, Mr. H. B. Taylor has suggested that the runner of the turbine should be put, if necessary, below the level of the tail water and arranged to discharge upwards. By making the discharge flow over a crest, or weir, set at a level above that of the tail race, it is then possible to unwater the turbine whenever it is necessary, for inspection or similar purposes.

A plant arranged according to these ideas is shown in Fig. 4, while Figs. 5

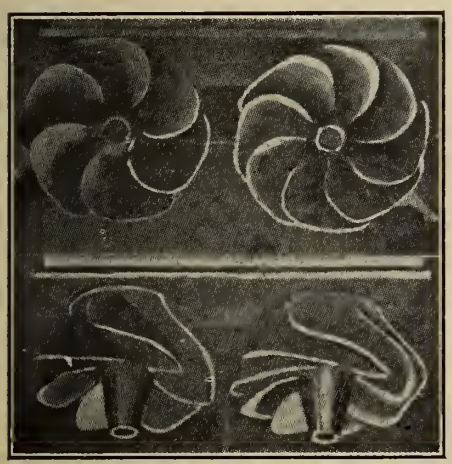

Fig. 3. New Type Turbine Runner

and 6 illustrate turbines adaptable to such a scheme.

In Fig. 4 the turbine is arranged with wicket gates or movable guide vanes, operated from below, in a pit provided for the purpose. The draught tube is of the spreading type, the outer barrel of the tube being used to form a circular crest to exclude the tail water when access is desired to the interior of the turbine. The procedure would be to close the head gates and to pump out the water contained by the draught tube and turbine passages by the use of centrifugal pumps or an hydraulic ejector.

Without going into all of the new features opened by this arrangement, it may be mentioned that the turbine casing, which is under a considerable amount of pressure, is placed at a low level in the power-house substructure, where there is a large mass of concrete above it to counteract the upward pressure of the water. An excellent design of draught tube can be used without requiring any increased depth of excavation.

The arrangements shown in Figs. 5 and 6 can be readily understood from the drawings. In the turbine in Fig. 5 wicket gates are used with the guide vane stems carried up through, or in line with, the draught tube stay vanes, which are used to support the superimposed structure, and outside operating mechanism is used, arranged in the usual manner in the turbine pit. In Fig. 6 a plunger gate is used instead of the usual wicket gates, this plunger being operated by hydraulic pressure.

"WHY DO RIVETS LEAK"

The real underlying cause for leakage at the riveted joints of boiler plates is often times difficult to place, necessitating a thorough consideration of the details in their design and construction. The answer to this question, "Why do rivets leak?" is one upon which much time and money has been spent to find a satisfactory answer. Modern investigation has, however, revealed the fact that the answer is partly found in the rivet itself,—its constitution and its physical structure.

It will be of interest to many to know that scientific methods of steel making combined with rigid chemical and physical testing does exclude the possibility of sulphur or phosphorus being present in high enough amounts to cause ruinous "cold" or "red shortness" in the rivet metal. In addition to this, the physical structure of the metal is given the utmost consideration by the progressive rivet manufacturers of today, who subject their steel to a process of cold working and annealing which increases greatly the strength and ductility of the rivet.

Failure of a joint is due at times to the selection of unsuitable rivets of such proportions that they must be unduly worked and strained to fill the rivet hole and form the head. It is also necessary that there be enough material to form a head that is at least as strong as the body of the rivet, and that the body length be not more than six times the diameter, since the stresses induced by contraction of the body increase with the length and may become so great as to cause the head to fly off.

Faulty design of joints is another contributor to leaking and failure. So careful consideration must be given to the type of joint used—whether it be lap or butt; single riveted, double riveted, triple riveted,etc. The pitch and diameter of the rivets must be so proportioned that the strength of the rivets in shear will approximate the strength of the plate against tearing; while both must be of such strength to withstand any shearing, bending or tensile stress they may receive. Reference to well established formulae abundantly illustrated that the stress in a girth lap seam works out at one-half the stress in a longitudinal joint. As a consequence it is permissable to use a lap joint for a girth seam, even though its strength is only a little better than one-half that of the butt seam. It should be noted, however, that the lap seam has a tendency to break or crack along the seam, which of course results in leaks.

Even the method of making the rivet holes may be responsible for the leaking of a boiler. Punched holes decrease the tensile strength of the plate between holes from 8 to 35 per cent. This may be corrected if the diameter of the hole is increased ¼ in. by seaming or drilling, thereby removing deformed material. If the holes are drilled instead of being punched the tensile strength of the plate between holes is increased 10 per cent. (for the spacing generally used). In many cases it happens that rivets are overheated before being driven and are consequently very susceptible to failure.

Riveters themselves are sometimes at fault, for there are many factors in driving rivets that need to be carefully observed if the resultant joint is to be tight. The plates being riveted should be held firmly together with tack bolts; and the rivets themselves should be hammered in place until redness disappears. This will prevent yielding of the head of the rivet, and the tension created by the contraction of the rivet shank in cooling will create high friction between the plates and prevent them from slipping. The importance of this point will be appreciated when it is considered that the rivets also contract laterally and do not completely fill their holes when cold. Before shearing can take place in rivets it is consequently necessary that the plates shall slip on each other. This slipping, which if in any appreciable amount will cause leaking, is prevented by the contact friction of the plates induced by the tension in the rivets and i creased by proper caulking.

The final operation to prevent leaks is caulking. A good job of caulking, as stated above, increases the strength of a joint by increasing the resistance of the plates to slipping. To secure a maximum of safety and strength rivets and plates should be caulked on both sides.—"Steam."

New Oxygen Plant Augurs Industrial Improvement—In these days of general industrial improvement it is refreshing to note the spirit of optimism evidenced in the announcement recently authorized, that the Dominion Oxygen Company, will break ground in mid-July for a new quarter-of-a-million-dollar oxygen plant at Montreal, which will double the company's present capacity. The building will be 100 ft. × 100 ft. and, will be substantially a duplicate of the company's Toronto plant, which until now has supplied oxygen to Canadian industrial users through five district distributing stations. The Montreal plant will be the second of five producing plants projected at the time the company was organized last year.

Graphite Lubrication, is the title of a neat booklet published by the Quebec Graphite Company, Buckingham, Que. Miners, millers and refiners of lubricating flake graphite. The contents describe the different characteristics of one of Canada's leading products, how the flake graphite is separated from the other grades and used for lubricating purposes, while the finer grained portion is used for lead pencils, stove polish, foundry facings, etc. Several views are shown of mines, concentrating plant, power plant, etc. All told, it is an interesting descriptive book.

The Perennial Smoke Consumer

THE SMOKE consumer, like the poor, we have always with us. It comes, like the ghost of Hamlet's father, in questionale shape, and its variety is infinite. In its various disguises it appears and struts the stage for a brief period, and vanishes, to be succeeded after a time by another emanation.

We are moved to these thoughts by the recent experience we had of a misguided stock salesman who approached us with the idea of selling us some stock. This stock was in a company which is putting on the market what the salesman described at different times to be a world beater, a sure-fire winner, and a scientific bobby dazzler. Apart from the fact that an editor belongs to a class who never have any spare money, this particular salesman had no chance of selling us stock in such a proposition. The inventor modestly claims that his apparatus will save at least 50 per cent of the fuel consumption of any boiler it is applied to. We intimated that if this was so all the interested parties needed to do was to take the apparatus up to the University and have it tested and their fortune was made. There would be no need to look for capital. Capital would fall over itself looking for them.

The smoke consumer occupies about the same position in engineering as Lydia Pinkham's Pink Pills do in medical science. Everyone we have seen can bring testimonials from dozens of satisfied users, but none we have seen yet have been able to furnish us with a duly authenticated, scientific record of a test. Nearly all of them depend for success on the introduction of a secondary air supply over the fire or in the combustion space, and as in most cases the cause of smoke is too much air to begin with, they do not help matters much. Even when they succeed in diluting the smoke it is no evidence that combustion has been improved. Complete absence of smoke is not a proof of perfect combustion in a boiler furnace.

Just imagine the amount of money that could be made by any company or individual that could actually save 50 per cent of the fuel burned in a plant of average efficiency, and what a benefactor he would be to the race. As to the man who can save 50 per cent of the fuel in a plant running at 65 or 70 per cent efficiency—words fail us.

Boiler Economy

IN ANOTHER part of this issue a correspondent writes about the old subject of fuel economy, and gives his own experience. He stated that in the plant where he worked he reduced the fuel consumption by one half and the number of boilers in use from three to one. In his letter he does not give details of the methods pursued, but we have invited him to do so, for the benefit of others.

This subject of fuel economy, while an old one, is ever fresh, fresh, and is being presented to countless men every day in a very vital way. Their ability to understand the subject and to achieve results measures their ability to retain their positions, or attain higher ones. The encouraging part of the matter is that practically every man has a chance to produce results, as there is hardly a plant in existence where some degree of betterment cannot be attained.

The large plant, which is usually well supplied with the necessary instruments, and opportunities for determining just exactly where losses are taking place, affords the best opportunity for attaining ideal conditions. On the other hand, it is the small plant where there is usually a noticeable absence of these aids to economy, where the greatest amount of improvement may be achieved by the man who really wants to get after it. The use of a draft gauge alone, which he can make from a gauge glass and a six-inch rule, will afford him valuable indications of the condition of his furnace and boiler settings. By means of a square box which will give him a means of accurately measuring the coal used he can compare results under different conditions of damper settings and thickness of fire carried, while a careful noting of the amount of coal dropping through the grate bars will show whether he is using the right type of bar for the quality of coal he is supplied with. Choosing the most favorable time for cleaning fires, careful attention to feed pump regulation, and a strict watchfulness on the physical condition of engines and auxiliaries will make a wonderful difference in even the smallest plants. All these things can be done by the careful fireman and engineer in the course of his daily duties, and the results will show very quickly.

The day of the happy-go-lucky man who is merely content to keep the plant running is fast approaching its end, if it has not already reached it.

Progress in New Equipment

THE NEW DIAMOND VALV-IN-HEAD SOOT BLOWER

AN ENTIRELY new principle has been introduced in soot blower design. The valve, controlling the individual unit, has been incorporated as an integral part of the head.

Let us for a moment briefly review recent developments in this important branch of power plant practice. The past few years have witnessed on the part of engineers everywhere, a marked growth in appreciation of the importance of rapid, thorough, mechanical removal of soot from the heating surfaces of steam generators. Coal and labor have constantly advanced in price. At the same time there have been unprecedented demands upon the boiler capacity of practically every boiler plant. The situation has called for systematic study of every factor affecting combustion. This analysis has proved the mechanical soot blower to be one of the best paying investments in the boiler room.

A large measure of the success of the mechanical soot blower has been due to the constant improvement in design and construction. Among the improvements of the past few years are the following:

1 The introduction of calorized metal for the protection of the blower elements from oxidation at high temperatures.

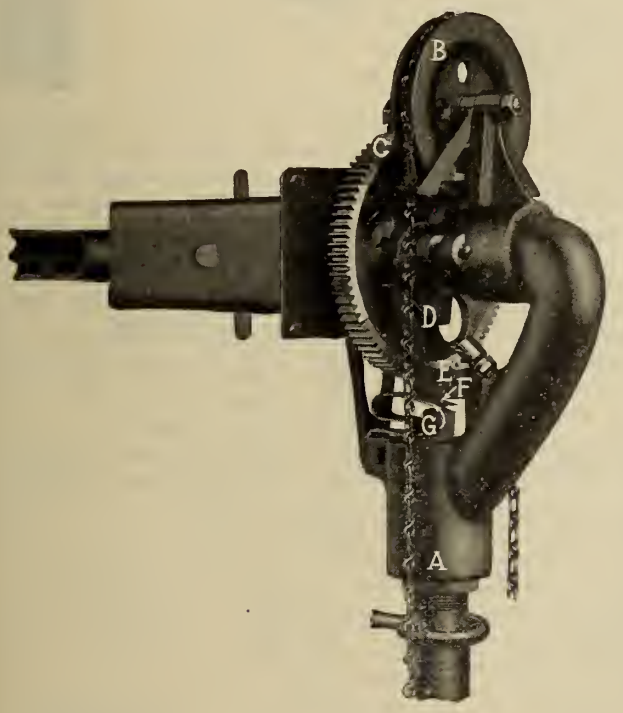
2 The adoption of nozzles of a Venture section to secure the highest possible velocity of the stream jets.

3 The development of special processes for welding these nozzles in place.

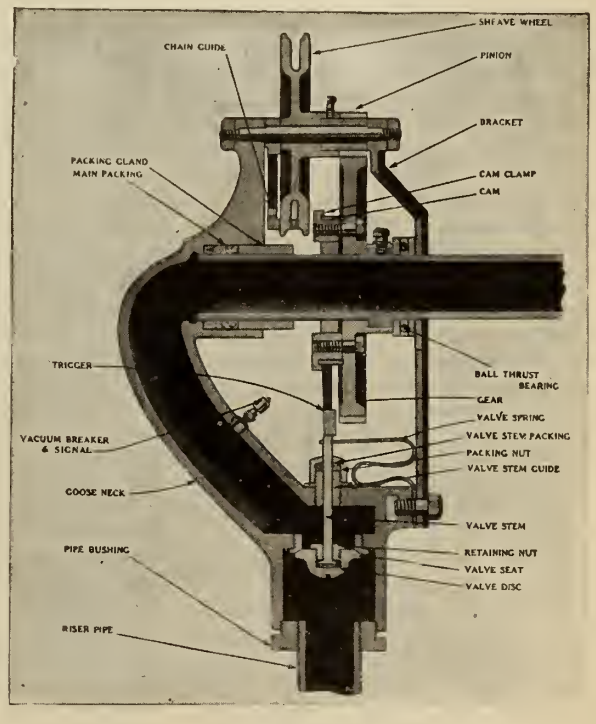
4 The designing of steel bearing to support the blower elements.

5 The introduction of the vertical header system of piping.

The successes heretofore registered have proved a spur to further efforts. Hence, we have the new Valv-in-head soot blower, manufactured by the Diamond Power Specialty Company, of Detroit, Mich.



General view of the apparatus.



Sectional View of the blower.

Head Constructed On New Principle

The Valv-In-Head soot blower is provided with a special Monel valve of the poppet type, placed at the base of the gooseneck. This valve takes the place of the globe valve which has always heretofore been installed (at a distance of two to fifteen feet or more from the head) in the riser pipe leading from the main header.

The special valve just referred to is located at the point marked "A" in the illustration, Figure 1.

The unit is operated in the following manner: The main control and drain valves which are the only independent valves on the soot blower line, having first been opened, and all piping drained and heated, dry steam fills the line to the entrance of the individual valve at the base of the gooseneck "A". The sheave wheel "B" is then revolved by pulling the chain. This turns a small steel cut pinion gear (not visible in the illustration). The small pinion engages the large gear "C" which is fixedly mounted on the blower element. As the gear is revolved, it operates a cam "D" which causes the lever "E" to press down the steam stem "F", causing the valve to open at a predetermined point in the revolution. After the gear has been further rotated, the cam "D" releases the lever "E", allowing the steam pressure to close the valve at a second predetermined point in the revolution. As steam leaves the line, the spring "G" holds the valve closed.

Construction of Valve

The valve is made with the Monel metal disc and seat. Both the steam and

its retaining nut are made of nickel steel. In order to secure extra hardness, which insures durability, the end of the stem is heat treated. A special feature is the provision of a guide on the seat, which permits leaving the stem loose in the disc so that the valve will always seat properly. The entire construction is such that the troubles common to globe valves, such as "wire-drawing," leakage, etc., are almost entirely eliminated. Disc and seat are readily accessible so that they may be removed easily for regrinding or renewal, should occasion ever require

As the tendency towards high pressure and superheat is very marked in modern power plant design, the Company manufactures a special body Valv-in-Head soot blower for such boilers as require this type of equipment.

Cam and Lever Construction

The movement of the cam is positive, assuring complete automatic opening of the valve at each operation. The cam and the clamps which hold in place are made of steel. The length and relative position of the cam is individually determined for each unit at the time of the installation.

The valve lever, which is also made of steel, is designed with a ratio of two to one, and as the reduction of the gears is ten to one, the opening of the valve is as readily accomplished as is a lever with a power arm of one hundred inches and a resistance arm of five inches was used. The spring is made of chrome vanadium. As the spring is away from heat, it always keeps its tension.

Vacuum Breaker and Signal

A very unique idea has been successfully worked out in the Valv-in-Head blower. Each head is provided with a vacuum breaker for the purpose of preventing the suction of furnace gasses into the blower element during the periods when steam is off the unit. In the present head this vacuum breaker has been designed in the form of a small brass whistle.

During the time the soot blower is in operation, the whistle sounds, furnishing both an audible and a visible signal, so that there is no opportunity for the operator to leave steam on the unit for a moment during which he is not revolving the blower, without the fact becoming readily apparent to any one in the vicinity.

Chain Guides

An important feature of the Valv-in-Head blower is the provision of guides to prevent the chain from slipping off the sheave wheel. It is not always convenient for the operator to stand directly under the unit, and the use of the chain guides enables him to operate the blower from any convenient point, without facing the posibility of having to hunt up a ladder in order to replace the chain on the sheave. The chain guides, in common with many other parts of the head, are made of steel.

A very marked step forward has been taken in the design of the Valv-In-Head soot blower, through the provision of a ball bearing to relieve the friction caused by the thrust of the unit, due to steam. As will be seen from the cross section of the head, this ball thrust bearing is located directly back of the steel wall bracket which supports the blower element. Its presence relieves friction so completely that the Valv-in-Head unit turns as readily when the steam is on as when off.

Floating Features Of The Valv-In-Head

The necessity for some means of eliminating the binding of soot blower units resulting from movement of the boiler tubes under the forces of expansion and contraction, is now generally recognized. An important developement in connection with the Valv-In-Head soot blower is the wall-box, with floating mechanism, which provides a means of taking care of any shifting of position of the blower element without causing dislocation of the wall-box, cracking of brick work, or expansion strains on soot blower head and brackets.

Elimination of Condensate.

One of the most important results of the use of the Valv-In-Head blower is the practical elimination of the possibility of water entering the portion of the soot blower inside the boiler. With the independent valve type of soot blower, the valve is located anywhere from 2 to 15 feet or more from the head. This means that condensation will inevitably take place when the valve is admited to the cold line. The water thus formed is driven through the soot blower head and into the blower element.

In addition to the condensate thus formed in the line a more serious possibility is that a small leak in the valve will cause water to form in the pipe before the valve is opened. When this occurs, a solid column of water may be built up in the riser pipes and carried over the boiler when the valve is opened.

The presence of this condensate in the hot blower element is apt to cause warping and its discharge on the boiler tubes may cause the soot to pack, forming a gummy mixture hard to remove.

With the Valv-In-Head system, any condensate in the main supply line is discharged through the drain pipes before blowing begins. There is, therefore, no water below the valve which can be carried into the blower head, and the radiation area in the head itself is so small as to be negligible. Hence we have practically complete elimination of condensate from the blower element.

VICTOR DAMPER REGULATOR

The accompanying illustrations show the damper regulator manufactured by the Atlas Manufacturing Co., New Jersey, U.S.A. and known as the Victor Damper Regulator No. 3.

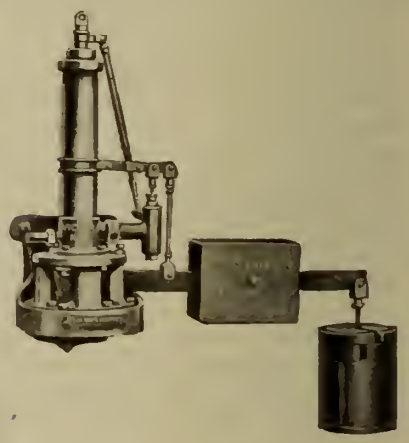
Installation

The regulator is furnished mounted on a cast iron bracket, which should be bolted to the wall adjacent to the boiler. The control piston should be connected to the damper with chain over pulleys, so that the damper is held wide open when the piston is down. The damper should then be counterbalanced so that it will close on an upward movement of the piston.

The water supply should be taken from the cold water line and connected to connection A (shown in illustration).

The steam pressure connection should be taken from the gauge line or boiler header and connected to the diaphragm at B (shown in illustration).

The discharge connection should be run from connection C on the pilot valve (shown in illustration) and run to any



convenient drain or to the ash pit.

By referring to the cut it will be noted that the direction of the water current is indicated by the arrows. The water pressure enters the regulator through the inlet A, passing to the pilot valve, then to the bottom of the control cylinder through port D. It also passes to the control cylinder on top of the piston through pipe E into the hollow piston stem and into the control cylinder through holes F.

The pilot valve stem I is of spool form with the upper head passing over port D. when above the port permits the water to pass into the bottom of the cylinder, and when below the port permits the water to escape from the bottom of the cylinder into outlet C.

By referring to the cut it will be noted that the area of the top of the piston is reduced by an amount equal to the cross-sectional area of the piston stem, whereas the area of the bottom of the piston is larger. We therefore have two opposing forces pushing against opposite sides of the piston, the constant pressure acting against the lesser area on top of the piston tending to force it down and the variable pressure from the pilot valve tending to push it up. Therefore when pressure is admitted to escape from the bottom of the cylinder the constant pressure forces it down.

Explanation of the Compensating Attachment

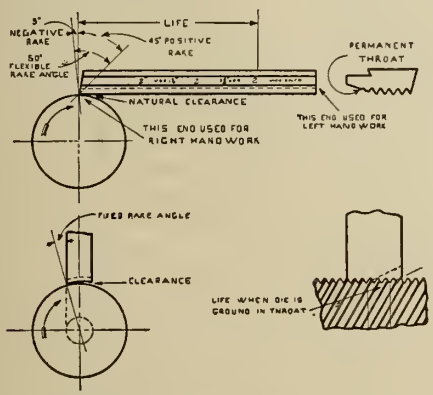
When the steam pressure under diaphragm G, is sufficient to raise lever H, the pilot valve stem I, is pulled up by lever J, swinging on axis K, this per-

(Continued on page 38)

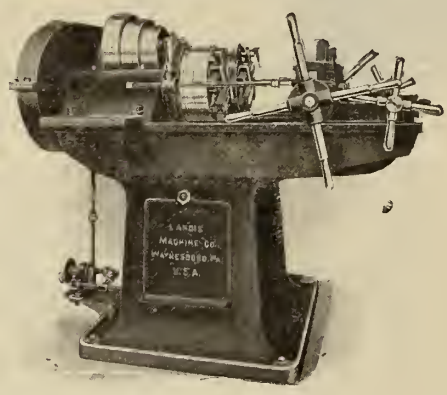
Landis Threading Machines

Standard Labor-Saving Equipment

Landis Bolt and Pipe Threading Machines do better work in less time because of the distinctive design of the Landis Chaser, which operates in the same manner as a lathe tool. Placed at a tangent to the work it allows the machine to operate at a higher speed than is possible when a hobbed type of die is used.



The diagram illustrates the main characteristics of the Landis Chaser as compared with the hobbed type die. It shows the long life of the Landis Chaser, and the fact that both right and left hand threads can be cut with the same set.



These are some of the special features that will help you lower the cost of production. Landis Thread-Cutting Machines are considered standard equipment by leading manufacturers, whose hardest jobs they handle with complete satisfaction.

We are the Canadian Representatives and our nearest Branch will gladly send detailed information.

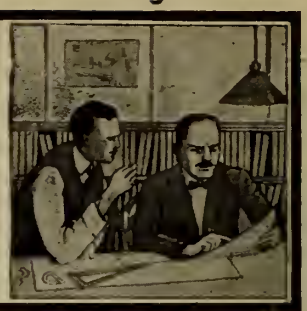
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered



WORKING OF INJECTOR

Question: Why will not an injector work when it is hot?

Answer: One of the conditions of successful working of an injector is that there shall be enough water passing to condense the steam. If the injector gets hot or the feed water to the injector is hot, this cannot take place and the injector stops working. A pump will not handle water if that water is hot enough to vaporize in the pump cylinder. The same thing applies to the injector. When the steam issues from the jet and its pressure is converted into velocity, its pressure falls below that of the atmosphere, and the water is forced up the suction pipe by the pressure of the atmosphere. If the water is at a temperature which corresponds with the boiling point at the pressure existing in the injector, it will vaporize, and thus defeat the condition of having sufficient water present to condense the steam.

* * *

WHAT IS THE ECCENTRIC

Question: What is the relation of the eccentric to a steam engine?

Answer: The eccentric performs the important function of giving motions to the valve gear, which gives steam distribution to the cylinder through the slide or poppet or drop gear valves, as the case may be. The eccentric is really a form of crank, but is made in the form of a disc or cam. This disc is keyed on the crank shaft of the engine, eccentric to the shaft, and it is this fact that has given the eccentric its name. The distance of the eccentric centre from the crank shaft centre is the throw of the eccentric, and its position in relation to the crank is its angle of advance.

* * *

HORSE POWER OF A BOILER

Question: How do you get the horse power of a boiler?

Answer: The horse power of a boiler is obtained from the rate of evaporation of the water. The standard boiler horse power is the evaporation of 34.5 lbs. of water from and at 212 degrees per hour. Boilers are rated for horse power on the square feet of heating surface, a horizontal return tube boiler having 15 sq. feet per horse power, a water tube boiler having 10, and a locomotive boiler 12.

* * *

STEAM PUMPS AND FLUE GASES

In answer to a question on steam in pump cylinder in July 20th P.H. it is stated that the steam is at boiler pressure up to the end of the stroke. I can not understand how this is possible in a well proportioned pump operating under proper conditions?

In answer to "A Combustion Question" it is stated "on the other hand air leaking in the setting cooling the gases down and producing a low flu temperature." If this air leakage takes place near the furnace of a water tube boiler in any part of the sitting of a return tube boiler the result is a higher flue temperature.

It might be interesting to know the views of other engineers on the two questions.

R. McLAREN.

* * *

HYDRAULIC TESTS

I have lost much of my faith in hydraulic tests since reading the artirle by Mr. Stroymeyer in the July 5th Power House. Is there such danger when the test is from 50 per cent to 100 per cent above the working pressure? Should the hammer test be used both before and after water testing? What pressure do you recommend to test at when using water? Express in per cent. above normal working pressure. Could the cracks spoken of in the article be as strong when exploded as when tested. If not why did water at a little higher pressure do so much damage that did not come to light when the greatest load was on it but did some months later?

C. F. PYE,
Wesley College,
Winnipeg.

The usual practice is to make the hydraulic pressure about 50 per cent. above working pressure. Personally, we have always been in favor of careful inspection to determine the condition of a boiler, and against the use of the hydraulic test for anything but a determination of tightness of riveting and workmanship after execution of repairs. In the case of a new boiler, the hydraulic test will show tightness and also if there is a weak spot in the design or material it will usually be shown if the test is carried out properly. The mere putting on of a water test to a certain pressure and then releasing the pressure after a certain interval does not give any information about the condition of the vessel tested. In making a test from which it is required to take deductions concerning the condition of the material careful measurements should be taken before and after the test, to ensure that there has been no permanent distortion. Regarding the hammer test, this is a somewhat ambiguous term, for there are many different ideas of what constitutes a hammer test. We have seen a man take a 14-lb hammer and deliver some pretty hefty blows to the shell of a boiler under hydrostatic pressure, with the idea of testing it. It certainly did test it, but it is not a practice to be recommended. As to the ordinary tapping of plates with a light hammer, it makes little difference when that is done. We do not believe there is any man living with an ear sufficiently delicate to distinguish the difference in sound given by a plate that has wasted a fractional amount when i is tapped by a hammer. There are of course places where the hammer test can give indications of wasting, but these indications must be carefully verified by drilling before any certain verdict can be given.

We remember a case of the misleading nature of the hammer test method in determining conditions. We were making an inspection on a B. &. W. boiler, and on examining the short nipples between the bottom back headers and the mud drum, one or two of them gave indications of being suspiciously thin, by the feel of the hammer. We called the chief engineer into the back end, and passing him the hammer, asked him to try the nipple. He also thought it thin, and trying one or two others, came to the same conclusion. He wanted then to have them all removed and replaced, but it was decided instead to cut out the one that seemed the worst, and see just what it was like. This was done and that nipple was practically as good as the day it was put in. A hammer test will not reveal grooving, nor will a hydraulic test but a careful examination will.

You may take a piece of metal and subject it to a steady stress which is very close to its elastic limit, and it will sustain that stress indefinitely. However, if you take the same metal and subject it to an alternating stress of the same nature, or it will fail in a comparatively short time. A boiler is designed with a factor of safety of 4.5 to 5. which means that its working stress is only one fifth of its ultimate breaking stress. However, its elastic limit of the metal from which it is made, is only about 2½ times the working stress, and in course of time, the

elastic limit will be decreased. If then a stress of double the working pressure is put on the metal by a hydraulic test, it may well happen that the elastic limit will be reached, or even passed, and while no indication is given to the ordinary observer, the metal is left in such a state that a very few more alternating stresses will result in failure. That is why the boiler in the case mentioned by Mr. Stroymeyer withstood the hydraulic test but failed soon after.

* * *

BOILER ECONOMY

As the Course of Instruction has now concluded I would like to see a description of the ways and means of handling coal to the best advantage. When you see the dense black smoke pouring from the stack you know coal is going to waste, as smoke, soot, and poor heating surface usually go together. Why not educate the men who have to burn this coal, that costs so much and is decreasing in quantity every year?

I took a plant where three boilers were being operated, and in less than four months I was running the same plant and same load on one boiler and using only half the coal, but I want to know more about economical combustion. C. F. P.

There has been a considerable number of articles in the recent past on this subject but we think our correspondent's suggestion a good one. In the meantime will our correspondent give us a detailed account of the methods used by himself in effecting such a great improvement inhis own plant?—Editor.

* * *

TAIL END RODS

I would like to ask readers of the Power House the following question. Why is it that we hardly ever see tail end rods on horizontal engines? I know a few of the local objections that are entertained by designers and engineers. Of course on marine work I can quite understand why they are not in use on any vertical job, but I think that horizontal jobs above a certain diameter, say fifteen inches, should be fitted with tail end rods.

The above is my own opinion, and I would like to hear from readers of Power House, to find out their opinion.

T. WALSH,
Port Au Port, Nfd.

* * *

THRUST IN CONNECTING ROD

Referring to the article on this subject in the July 20th issue and previous issues, the contention of Mr. McLaren is perfectly correct, and the mistake was ours. It is perhaps unusual for a technical paper to make a mistake in a matter of this kind, but it is highly important that having made a mistake that we should promptly admit it and rectify the error, for our readers must not be misled.

We wish to thank Mr. McLaren for his efforts in pointing out this error, and several correspondents whose letters cannot be published for lack of space.

If there is any cause for gratification over this matter, it is in the fact that so many of our readers evince such an interest in the "Question Box," and we hope indeed that should we ever make another error that we shall have the critics down upon us with their utmost force.

Full and free use of the question page can tend only to the benefit of all those who use it, and the more the better. We can assure all of a fair field and no favor.

* * *

EFFICIENCY OF ENGINE

Question:—A steam engine of 120 H. P. drives a D. C. generator, the capacity of which is 250 Amps for 24 hours at 240 volts. The efficiency of the generator is 88 per cent. What is the efficiency of the engine.

Answer:—We are afraid from the way the above question is written, that our correspondent is not very clear on the subject of generator and engine efficiency. The capacity of a generator is measured in Watts, or Kilo watts, which is the product of volts × amperes. It is not affected by the length of time the generator is running. The generator in question is evidently of a maximum capacity of 250 Amps. at 240 volts, that is, 60,000 watts or 60 K. W. It is only the discharge of a battery that is reckoned in amperes × time or ampere hours. If its efficiency is 88 per cent. it would deliver at the switch board 60 × .88 or 52.8 K. W. The mechanical efficiency of the engine will probably be about 90 per cent. The actual mechanical efficiency of the engine can be found by dividing the indicated horse power as found from the indicator diagram, by the actual capacity of the generator, or by the brake horse power.

* * *

POWER FROM WOOD REFUSE

At a recent agricultural exhibition in England many different British makers of suction gas plant were shown, some of them in operation driving engines. They ranged from 2 to 65 horse power, the largest making gas from saw mill refuse, bark, shavings, or other wood waste, and the smallest using charcoal. The big plant takes only from two and a half to three and a half pounds of wood per brake horse power per hour, according to the quality of the wood refuse. The little one is mounted on its engine on a wooden truck so that it forms a complete portable power plant. Visitors to this exhibition were struck with the high class workmanship of this equipment which will be a boon to farmers and foresters in parts where charcoal is available.

Gelinas and Pennock Reg'd, Engineers, of 207 St. James Street Montreal, have recently been appointed sole Canadian agents for the Cokal Hand Automatic Stoker, made by the Cokal Stoker Corporation Chicago.

10,000
Indorsements

Whenever a manufacturer replaces a cumbersome bucket or float type of trap for the simpler, compact, more modern Sarco Steam Trap, he automatically indorses the greater efficiency of the Sarco. And many manufacturers are doing that very thing every day.

As a good example, there's du Pont—the mighty du Pont of explosives—the E. I. du Pont de Nemours Company. This great company, wise in the ways of success, has over 10,000 Sarco Steam Traps saving money by conserving steam and coal.

Why has du Pont installed the Sarco? Easy; there are two reasons. One is: good judgment on the part of the du Pont engineers and buyers. The other is: good service on the part of the Sarco.

The Sarco costs but one-third the price of a clumsy bucket or float trap, and renders better service. It is minus all the claptrap of unnecessary levers, gauges, packing and stuffing boxes, yet it is literally a valve, a bypass, a check valve and a steam trap all in one. Goes in as an elbow, too.

Du Pont engineers realized the economy of the Sarco. They know that it is cheaper to put in a new Sarco complete than to repair a worn out float in a float trap. A float costs about $12.00, whereas a new Sarco, one-inch size, costs only $9.60 net.

If you would like to satisfy yourself, we'll gladly send you a Steam Trap Sarco on 30 days' free trial.

Sectional View of Regulator

VICTOR DAMPER REGULATOR

(Continued from page 34)

mits the water to pass into the bottom of the control cylinder and force the piston up.

As the piston moves up rod L is pulled upward in sleeve M, which is rigidly attached to lever N, swinging on axis O. As the point where rod L is attached to the piston stem travels in a straight line, the angle at which sleeve M stands is lengthened and to meet this longer angle sleeve M must swing outward, which depresses axis K on the end of lever N. This pushes pilot valve stem I down so that the upper head of the stem covers port D, and shuts off the water supply to the bottom of the control cylinder which checks the upward travel of the piston.

When the steam pressure falls, lever H lowers and pulls pilot valve stem I down, so that its upper head is below port D. This permits the water in the bottom of the control cylinder to escape into outlet C, which allows the constant pressure on top of the piston to force the piston down.

As the piston moves down rod L, sliding into sleeve M, shortens the angle at which sleeve M stands and to meet this shortened angle, sleeve M must swing inward, which raises axis K, and pulls pilot valve stem I up so that the upper head of the stem covers port D, and shuts off the water discharge from the bottom of the cylinder, which checks the downward travel of the piston.

The importance of the compensating attachment cannot be overestimated as it acts as an intermediary medium to counteract the movement transmitted to the pilot valve by the steam pressure under the diaphragm, which balances the position of the damper on intermediate pressure changes, and permits the damper to be fully opened or closed only on extreme boiler pressure variations.

NEED OF INSPECTION

The Editor, Power House:

Enclosed is a clipping from a local paper and it shows the need of some one to inspect such boilers and report to those higher up. I would suggest that if it could be done one man should be appointed in each county to inspect such boilers as these, the inspection fee to be paid by the owner. It might help to improve the care given by those in charge.—N.E.A.

"The corporation's road roller has been inactive for the past day or two on Thames street north. A crack in the boiler is held responsible, and in turn, carelessness is held responsible for the crack. A boiler expert from Woodstock was working on the machine yesterday, and stated positively that nothing but carelessness could be held responsible. He had to chisel through the thickest boiler plate he has encountered in a lifetime of boiler work in an effort to remove the cracked portion. Within he found the scale and sediment of long term of carelessness. "This sedament should be cleaned out every two weeks" said he. "In this boiler there was a great thickness of scale. The water could not get to the plate, with the result that it soon burned and cracked. Every boiler should be washed out at least every two weeks. That prevents the accumulation which means boiler ruin. This boiler had the best material in it I have ever worked with, and with any kind of care, would have lasted a lifetime."

One of the workmen present stated that the idea had been advanced that the roller is used only about two weeks in every year, and there had not been the proper precautions taken on that account.

"It makes no difference how long it is used in a season. It should be washed out every two weeks while in use. It should then get another cleaning out when put away for the year. Unless this is done, it cannot be expected to be in good shape when taken out the following spring."

A large patch has to be attached to the outer surface of the boiler, and it was expected that this would have been completed by Thursday evening. The expert was asked what it would cost to put the boiler in good shape, flues, boiler and all.

"I would say roughly that it would cost over a thousand dollars" said he. "Of course I have not gone into the matter, but I would say that with a fair degree of certainty. That is the price of carelessness. This is an excellent boiler and would have lasted indefinitely had it been given proper attention. There are too many bosses in council jobs, and too many having the care of the roller in their hands. There should be some one who would see that a corporation machinery of this kind was given the attention it should have, and there would be money saved for the corporation."

The above is an example of the need of inspection of all boilers, whether large or small. This is a case evidently where every one's job is no one's job. It would be interesting to know how many cases like this occur in a year.

We had occasion to inspect several boilers of this type some years ago in an Ontario brickyard, and the internal condition of these boilers was little short of disgraceful. The owner was profoundly surprised when we mentioned the necessity of cleaning them and said they had never been cleaned during his ownership, which extended over several years. He had recently had them insured, hence the inspection.

The Armstrong Cork Company, of Pittsburgh, Pa., have issued a small folder entiled "Four Reasons" which describes the use of the Nonpareil High Pressure Blocks and Cement manufactured by the company. These are designed for insulation of all high temperature equipment.

Mr. H. T. Day, of Mirlees, Bickerton & Day Ltd., who are the manufarturers of Mirlees Diesel Oil Engines, is at present in Canada on an extended tour. The firm Mr. Day represents have a large number of engines installed in various parts of Canada, and Mr. Day purposes visiting each installation during his trip.

Some Advice to the Boiler Attendant

These Notes are Taken from the Annual Report of. Mr. C. E. Stromeyer, of the Manchester Steam Users Association, England. They are Worth Reading as Coming from a Very High Authority

*By HERBERT R. REYNOLDS

Economy

THE coal bill for a Lancashire boiler amounts to from $4000 to $6,000 per annum. Careless stoking may easily increase this cost by a few hundred pounds, and is sure to throw much extra work on the stoker. The best stokers do the firing rapidly but judiciously, keeping the firedoors open for the shortest possible periods.

The best results, with a minimum of labour, are attained when each boiler discharges a light smoke. Absence of smoke, except from coke or smokeless coal, indicates that much heat is being wastefully blown up the chimney in the form of useless hot air, which air has been admitted in excess above the grate or through brickwork cracks. Dense smoke is also wasteful and occurs most frequently with over-worked boilers. It is produced in furnaces which are nearly choked with coal, or whose doors or grids are insufficiently opened. Most fuels require some extra air through air grids in the doors immediately after firing, but when the coal is burnt through, the extra air supply should be reduced.

Air Leakages through cracks in brickwork are always wasteful. Such cracks would show up as black lines if the boiler outsides, including blow-off pits, were frequently whitewashed.

Mechanical Stokers.*—The leading types are the sprinkler stoker, the coal stoker, and the underfeed stoker. They should be maintained in perfect working order. Their designs are based on the experiences gained with particular qualities of coal, usually dirty slack, and unsatisfactory results are obtained if the particular quality is not used. Mechanical stokers which may have been intended for impure coal would burn away or melt if very clean and, therefore, very hot coal were used. Financially it is an unsound principle to aim at a superlatively high efficiency, for this is associated with intensely hot flames and costly repairs for wear and tear.

Dangers.—A boiler may empty itself overnight, or if the blow-off cock or feed valves are leaky, the boiler may empty itself while steam is being raised. It is, therefore, imperative that the water-guage glass should be tested before starting fires, and should be watched while raising steam; it should also be carefully watched during working hours, even if automatic feed-regulators and low-water level alarms or safety valves are fitted, for if these appliances should stick fast, the boiler may empty itself without warning, resulting in bulged furnaces. In the event of shortness of water every effort should be made to cool the furnace plates, the most effective means being to turn on all available feed water and to cool the fires by covering them with ashes or green coal. The furnace doors should also be opened and the dampers partially closed. Modern furnaces being made of steel, rarely burst when bulging, and it is only in cases of prolonged and serious overheating that a collapse leads to an explosion.

Automatic Feed Regulators are a source of danger, for whereas without them a collapse cannot well take place unless the feed supply stops, the water level sinks, and the attendant neglects his duty, a collapse will follow as a matter of course if any single part of the mechanism of an automatic Feed-Regulator gets out of order.

Corrosion

The chief cause of internal corrosion or rusting of boilers and economisers is the unavoidable presence of the oxygen and carbonic acid which are dissolved in all feed waters. This air is liberated wherever the circulation is sluggish, as in economiser pipes and in the bottoms of boilers. It attaches itself in minute bubbles to the metal and corrodes it, particularly if the plates are not covered with scale. The most effective preventive for this kind of corrosion is the continuous addition to the feed water of vegetable extracts like tannin, or of caustic soda or caustic lime. The caustics neutralize the carbonic acid gas of the air in the water, whereas the vegetable extracts destroy the oxygen gas. The addition of a little caustic lime to very pure feed water has the further advantage of leading to the formation of a thin protective scale.

Internal Corrosion may also be due to the presence in the boiler water of neutral salts, for they lead to galvanic action. Hence brackish waters, which contain common salt and chloride of magnesia, and softened waters, which generally contain sulphate of soda or other soluble impurities, are also sometimes corrosive. Comparatively small traces of any of these salts in the feed water rapidly concentrate in a boiler, unless it is occasionally blown down a little, for during working hours the entire volume of water in a Lancashire boiler is evaporated, and has to be renewed by the feed in about five hours†. Thus if the feed contains 14 grains of salt per gallon, or 1-50 per cent., the boiler water would, after 1,000 hours steaming, contain 4 per cent. of salt. With locomotive and winch boilers the density increases much more rapidly.

Scale or Incrustation, as well as mud sediments, are introduced into a boiler with the feed water in which they are dissolved, and from which they separate out as the water is being heated or evaporated. Most hard scales contain sulphate of lime (plaster of Paris) which can be converted into softer carbonate of lime (chalk), by the addition of soda ash to the feed, but no treatment of water in the boiler will reduce the amount of deposit; it will at best alter its character and facilitate cleaning. The slight trace of grease, which mere filtration will not remove from condenser waters, is the cause of slow but often serious bulging of furnace tubes.‡

Water Softeners are vessels in which the feed water is mixed with certain chemicals in suitable proportions, causing the scale-forming impurities and grease to be precipitated. These precipitates have to be removed both by settling tanks, and by filters. They should be of large dimensions, otherwise the precipitates may be carried into the boiler. The oftener the feed water is tested for hardness and the addition of chemicals regulated accordingly, the more thorough will be the purification. If possible, the water should be treated warm.

Water Softeners which are not properly worked can do more harm than good, even to the extent of increasing the deposits in boilers and attacking the gun-metal fittings.

Water Softeners do not remove soluble salts, such as common salt or sulphate of soda. On the contrary ,they add either the one or the other of these salts if the feed water has permanent hardness. Water softeners are the most effective devices for removing all but the very last traces of grease from condensed waters.

---

* For water-tube boilers the following remarks apply:—

Brickwork Wastage. The intense heat of mechanically stoked fires and the contact with the brickwork of fuel which contains lime leads to rapid wasting away, entailing heavy brickwork repairs. It is, therefore, advantageous to use a clean coal and to restrict combustion near the brickwork sides.

Mechanical Stokers for water-tube boilers are generally of the chain grate type. They are designed to burn small coal and usually do this economically, but, as their repairs grow very expensive if they are not kept in working order, all defects should be made good as soon as noticed. With chain grates the thickness of the bed of fuel and the rate of travel can be varied at will and the draught can also be regulated by the dampers. It is, therefore, possible to obtain either very good or very bad economic results. The best conditions will have been attained if the fuel has just finished burning when it reaches the end of its travel, the grate being covered with fuel from end to end; but this is not always possible if the duty of the boiler is irregular.

Dangers. On account of the large amount of heat stored in the brickwork of water-tube boilers, especially if they have been worked heavily up to the time of stopping, there is always the danger of the water in the boiler being evaporated while standing idle

† In a water-tube boiler the water will be renewed in about two hours time.

‡ In water-tube boilers scale and grease ought not to be allowed to exist.

External Corrosion usually occurs under damp boiler coverings, walls and seatings, ashes and flue dirt. Ashes should, therefore, not be slaked against boiler fronts, leakages of shells and furnaces should be stopped, and drippings from roofs, steam pipe flanges, or drain cocks should be prevented from falling on boiler coverings. Any suspicion that there is a leakage under a boiler covering should be acted upon at once.

Flue gases are heavily charged with acids and moisture, especially if steam jets are used in the furnaces. This moisture and acid readily settles on the cold lower parts of economisers and corrodes them. This corrosion can be prevented by warming the feed to 120o Fah. if steam jets are used in the furnaces, otherwise a feed inlet temperature of 100o Fah. will suffice.

Idle Boilers should be kept in a warm condition, especially if they are full of water ready for immediate use, otherwise dampness will cause serious wasting on the outside. If a boiler is to be laid off for any length of time, it should be scaled, washed out and dried, trays with unslaked lime should be placed inside, and all openings should be closed so as to keep out the damp air. Boilers which are not closed up in this manner often waste away more rapidly than those which are in use.

Economizers are as a rule built of cast iron. This is an unreliable material and occasionally pipes fail from the date of erection. As the water is relatively cold no explosions result. Such failures would be real explosions if the economiser water were in a boiling condition. Therefore, always open the bye-pass of an economizer when the feed does not pass through the economiser.

Boiler Inspection

A boiler must be completely opened out and all scale removed before inspection. The boiler coverings should also be removed occasionally, and the seatings exposed, unless the inspector can satisfy himself by other means that there is no external corrosion.

In addition the boiler should be frequently overhauled, say after 1,000 hours steaming, if good feed water is used, or after 250 hours or less, if a sedimentary or corrosive water is used.* On these occasions mud and scale should be removed. Whenever possible, the boiler shell plates in the flues should be freed from soot and tar deposits, for these are amongst the worst known conductors of heat. It is for this reason that economisers are provided with scrapers which remove these deposits continuously.

Before removing the manhole covers of a boiler, at least one safety valve should be permanently opened, for, if there is either a pressure or a vacuum in the boiler, the manhole door may be blown off, or into, the boiler. The junction valve and the blow-off tap should be padlocked or otherwise secured, so that these cannot be opened while men are in a boiler.

Leaky cocks, valves, and joints should be made good whenever a boiler is laid off.

It is very desirable that candles and a chisel should be provided before the inspector arrives.

Steam Pipes

The opening of steam valves and drain cocks should be done carefully, as is proved by the fact that many steam-pipe explosions have occurred when one boiler attendant has been replaced by another who was unaware of the order in which the valves and cocks were opened and closed. The attendant should be quite clear in his own mind that wherever steam and water meet in a confined space there a water hammer may occur. The "singing" of kettles when just on the boil is due to numerous but minute water hammers. With high-steam pressures and large volumes of cold water in long pipes, the water hammers are so intense that they will easily fracture the strongest steel pipes If cracking noises (water hammers) are heard in pipes, their causes should be inquired into.

The attendant should take it for granted that all low-lying steam pipes, especially long ones, all low-lying bends junction valves, and all pipes between bulb valves are pockets in which water from 1in. to 1 1-2in. per foot of diameter, will condense in a range of pipes as soon as steam is turned into it. This water cannot be forced out suddenly, but must be removed slowly, and very often much water in a pipe helps to create a vacuum, and as there is then no outflow a fairly full pipe may be thought to be empty. A safe plan for coupling up a steam-pipe range is as follows:—

Open the Drain Cocks; these will either drain away the cold water or admit air, which, if a water hammer should occur, will soften the blow. Close the cocks before opening the steam valve slightly. After a time close the steam valve and re-open the drain cocks. These operations may have to be repeated several times.

Low-Lying Junction Valves, unless automatically drained, should not be drained or opened as long as there is steam pressure in the high level main.

Steam Traps of the expansion type admit air when pipes are cold, but neither these traps nor those of the floating type will drain a pipe in which there is no pressure, nor can they drain away the newly-condensed water. Therefore, if steam is turned on suddenly, steam traps cannot be expected to give protection. They should in any case be kept in perfect working order.

*For water-tube boilers read: say after 500 hours steaming, if good feed is used (sedimentary or corrosive water should not be used with water-tube boilers.)

169,000 W.W. OF TURBINES TESTED AT ONE TIME

The capacity of the Testing Room of the South Philadelphia Works of the Westinghouse Electric & Manufacturing Company was taxed to capacity recently when 169,000 KW of steam turbine generators were on the test floor at the same time. Nearly 150,000 KW of this amount was made up of five turbines for some of the largest power companies in the United States. Reading left to right, these turbines are as follows:

35,000 KW turbine for the Hellgate Station of the United Electric Light & Power Company of New York.

25,000 KW turbine for the Virginia Power Company, Cabin Ceek, Va.

25,000 KW turbine generator for the Gold Street Station of the Brooklyn Edison Company.

35,000 KW turbine for the Calumet Station of the Commonwealth Edison Company, Chicago.

25,000KW turbine for the United Electric Light Company, Springfield, Mass.

10,000 KW turbine for the American Rolling Mills, Middletown, Ohio.

Other turbines on the floor are a 3,000 KW low pressure turbine for the New Jersey Zinc Company at Franklin Furnace, N. J., a 1,000 KW turbine for the Tupelo Cotton Mills, Tupelo, Miss.; a 1,000 KW turbine for the Mobile Light and Railway Company, Mobile, Ala.; a 2,000 KW house turbine for the United Electric Light and Power Company, N. Y., and a 2,000 KW turbine for Takata & Company, Japan.

BRITISH INDUSTRIES FAIR, 1922

The next British Industries Fair will be held in London and Birminham between the 27th February and 10th March 1922.

The British Industries Fair is open to manufacturers in all parts of the British Empire and buyers from all over the world are attracted. It affords an excellent medium for bringing manufacturers in direct contact with buyers, as only bona fide manufacturers are invited. The general public are not admitted.

Full details regarding the Fair can be obtained from H. M. Trade Commissioner at 248 St. James Street, Montreal, 260 Confederation Life Building, Toronto, or 610 Electric Railway Chambers, Winnipeg.

ANNOUNCEMENTS

Operation, construction and safety features of type A auto-starters are given in leaflet 1610-C, which is being reprinted by the Westinghouse Electric & Manufacturing Company. This leaflet describes in detail the auto-transformer, switching mechanism, the contacts, the overload relays, and many other features of this apparatus.

* * *

Storage Battery Mine Locomotives is the subject of leaflet 1888-A which has just been printed by the Westinghouse Electric & Manufacturing Company. This leaflet describes the applications of storage battery mine locomotives, and illustrates and treats on the Baldwin-Westinghouse type of apparatus.

When You're Attending the C. N. Exhibition

Here's our headquarters. Right next the Union Station.

Visit Our Big Displays of

New and Used Power Plant Equipment

We're not at the Exhibition grounds this year but—we have fine displays of New and Used Power Plant Equipment in our own warehouses—and you can see them while on your way to the Exhibition.

Our headquarters, 131 Front St. West, is right next the Union Station. Step in when you get off the train. We'll be glad to see you. Then when on your way to the Exhibition grounds get off the car at 27 Bathurst St. Here we have 3½ acres of space devoted to the display of the most up-to-date equipment. Exhibition cars will pass our door. Don't forget to call. 27 Bathurst St. is the address.

3½ Acres of Floor Space Showing

Vertical Boilers

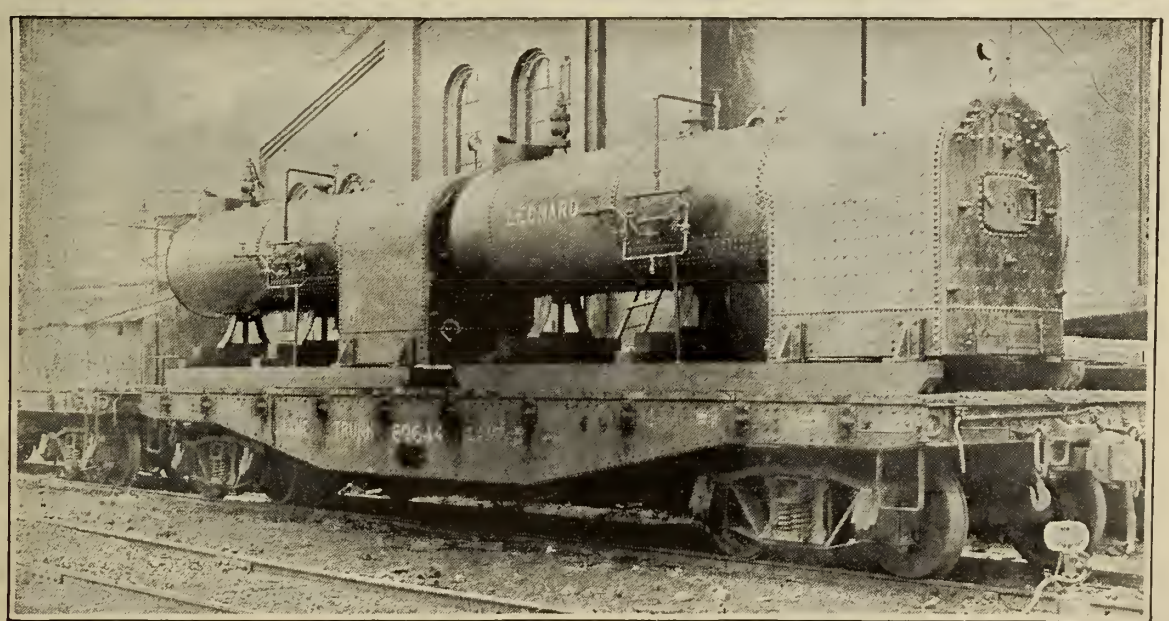
Horizontal Boilers

Firebox Boilers

Marine-Internal Fired

Engines of all kinds

H. W. PETRIE, Limited, Toronto and Hamilton



Two 60 H.P. Locomotive Boilers for 125 lbs. Under Ontario Regulations.

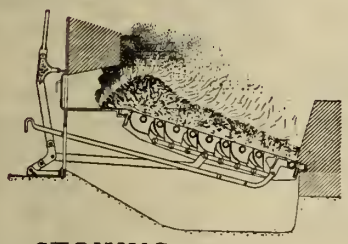
Stop Cleaning Fires By Hand

Fire Your Coal This Way

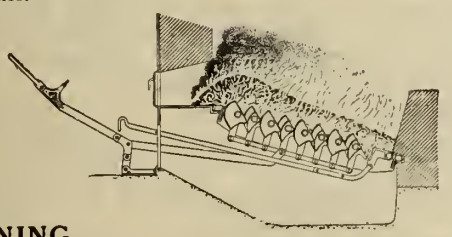


FIRING

Fresh coal laid on Front Gases must pass over fuel bed.

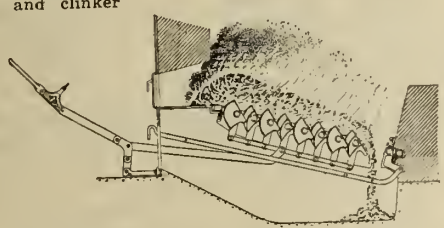
STOKING

Half throw of lever advances coked fuel evenly over stoker.



CLEANING

Full throw of lever and auxiliary discharge eliminates all ash and clinker at rear.



CoKal Hand Stokers save fuel, save labor and eliminate that hot, dirty, disagreeable job of cleaning fires. Also increase evaporation and efficiency.

Send for Illustrative Bulletin

GELINAS & PENNOCK, Reg'd.

207 St. James St., MONTREAL, P. Q.

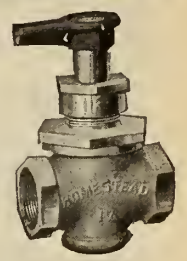
USE

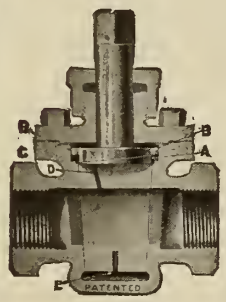
COKAL

HAND STOKERS

HOMESTEAD Quarter-Turn Valves

About thirty times as fast as globe or gate valves!





It takes from eight to ten turns of the wheel to open or close the ordinary globe or gate valve while a Homestead requires but **one quarter turn!** Think of the convenience, think of the time saved on any service where frequent opening and closing is required!

That's why HOMESTEADS have replaced globes and gates in hundreds of plants.

They are used for air, steam, water, oil, or acids and will keep your pipe lines absolutely tight.

HOMESTEAD VALVES are made in Straightway, Three-way and Four-way patterns.

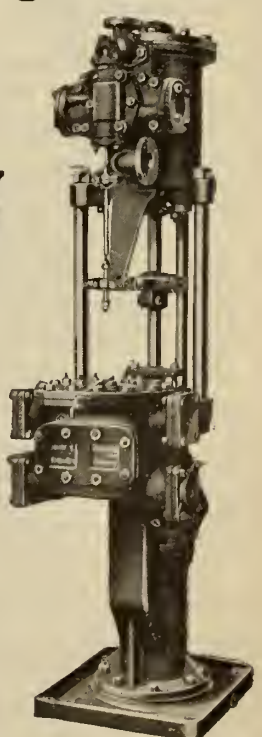
Write for catalogue.

Homestead Valve Mfg.Company

Homestead, Pa.

With the Single Gland

A high pressure pump for Marine and Land Service. It has only one gland on the ram to require packing.



HEPBURN

"Special" Vertical Ram

FEED PUMP

is the one pump to use where positive action with minimum attention and upkeep are required. It is an outside-packed type operating with positive Lever Valve Motion. The Pump Ram works in a brass Sleeve and the wear is evenly distributed as the weight of the ram and piston is taken by the water pressure. We are also makers of Vertical Engines, Compressors, Cranes, Cut Gears, and Iron Castings. **If interested write us.**

MONCRIEFF'S

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

"UNIFIC" WATER GAUGE

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

GLASSES

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Canadian Representative: W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA

Chimney Repair Work

Does your chimney need repairing? Experienced chimney foreman and expert repair man is open for engagements. Put your problems up to me. Rates reasonable.
Box 203, Power House.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHINERY; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECOND-hand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

FOR SALE—ONE 16-INCH, ONE 24-INCH Sheldon exhaust fans, practically new. Apply, Box 205, Power House.

SAWMILL MACHINERY MANUFACTURED by sawmill machinery specialists. Apply, mentioning Power House, The E. Long Manufacturing Co., Limited, Orillia.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

FOR SALE

1 H.R.T. BOILER—72-IN. x 16-FT. SHAKER grates and stack, complete; 125 lbs.
1 H.R.T. BOILER—60-IN. x 14-FT., 120 pounds. Apply, mentioning Power House to Wilson-McGovern, Ltd., Lumsden Bldg. Toronto.

THE JOHN INGLIS CO., LTD., ENGINeers and boilermakers. Write us for prices. 14 Strachan Ave., Toronto. Mention Power House.

FOR SALE—A NUMBER OF SECOND-HAND machine tools in excellent condition; these may be inspected at our works. Apply, mentiontioning Power House, The Waterous Engine Works, Co., Limited, Brantford, Ont.

SITUATIONS WANTED—MALE

ENGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

STATIONARY ENGINEER (2ND CLASS)—would appreciate steady position in country; references A1. Apply, mentioning Power House, to Box 218, Globe.

MECHANICAL ENGINEER, 29, FIRST-CLASS stationary engineer's license for Ontario, 10 years' power plant experience, saw-mill and paper mill; specialist in making repairs and operating plant economically, desires permanent position with large saw-mill or paper mill, preferably in New Ontario. Apply to Box 202, Power House.

STEAM ENGINES, BOILERS, HEATERS, tanks, stacks, pumps and condensers, transmission and elevating machinery, safes, vaults and vault doors; catalogue and specifications sent on request. Apply, mentioning "Power House," to Goldie & McCulloch Co., Ltd., Galt, Ont. (pfh)

FOR SALE
1 Sarco Recording CO2.
1 Taylor Recording Barometer.
1 Bristol Recording draft gauge, 0 to 1" water pressure.
1 Bristol Duplex Pressure gauge, 0 to 4" inches, 0 to 4" ounces.
1 Taglibue Viscometer.

Instructive Advertisements

"I think the advertisements are good and I read them all the time. If it was not for the ads. an engineer would not be able to keep up-to-date on new equipment. It is the only way we learn about anything new, as circulars are mostly kept in the offices," writes a Hamilton reader.

Double Moral—Read the Advertisements. Use POWER HOUSE *for Advertising.*

KELLOGG

A Name that Stands for the BEST in

CHIMNEYS

SECURING the **right** chimney for your plant is an important consideration. When you decide on a **Kellogg** you are safe! They have stood the test of time and have gained a world-wide reputation for reliability. The corrugated feature of **Kellogg** Radial Brick has proven a distinct advantage. The adhesion between mortar and **Kellogg** Corrugated Brick is 62½ per cent. greater than between mortar and ordinary straight or plain-sided brick; **Kellogg** construction is therefore safer and more endurable.

We can give you reliable advice on chimney construction — consult us before building your next chimney.

Canadian Agents:

Obtaining Increased Boiler Capacity At a Low Cost

Perhaps you need more boiler capacity but are limited in the floor and building space necessary for the installation of additional boilers. The way one plant met this situation is outlined in the following case:

This plant was operating its 1,000 hp. in boilers to the limit of their capacity but 250 boiler horsepower was still needed. By careful investigation it was found that a new boiler of 250 H.P. would cost about $11,000 (250 hp. at $44.00), including setting and brickwork, but not including floor or building space, additional auxiliaries, etc. It was disclosed, however, on further investigation that by applying superheaters to the existing boilers an increase in boiler capacity of 25 per cent., or 250 hp. could be effected. For the existing conditions at this plant superheaters to furnish 150 degrees superheat would cost about $6,000 (1,000 hp. at $6.00) delivered and erected, but no additional floor or building space would be necessary—a saving of $5,000 over new boilers to obtain the same additional capacity.

By installing Elesco Superheaters little or no more fuel would be consumed at the increased load than formerly; steam lines and engines would be protected from the dangers of water hammer; the entire plant would operate more effectively.

Our engineers will assist you in analyzing your conditions to determine just what it will cost you to effect an increase in capacity by installing Elesco Superheaters in your boilers.

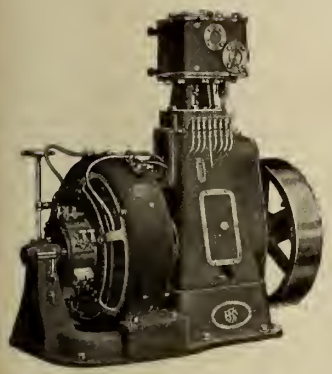
When the Load Runs Light

A much higher overall economy is assured by shutting down the main units during the off-load periods and by carrying your light load power requirements with a Sturtevant Generating Set.

Unsurpassed in reliability with a remarkably high steam economy over a wide range in load.

Ideal for the night shift and Sundays. A big money saver.

Hundreds of discriminating manufacturing and institutional plants have installed



Sturtevant VS-7 Generating Set

Sturtevant (TRADE MARK)

GENERATING SETS

Their reputation is founded on years of complete satisfaction.

The engine is of the simple short stroke high speed type, fitted with a piston valve and Ritter Shaft governor that maintains close regulation over widely fluctuating loads.

The generator is designed in full accord with the latest A. I. E. E. Code. It is guaranteed to operate without injurious sparking and to carry 25 per cent. overload for two hours.

The entire unit is mounted on a three bearing pedestal base with adjustable, Sturtevant White Metal lined self-aligning pedestal bearing. It is carefully finished and painted.

Tested at the plant before shipment to withstand the severest duty both mechanically and electrically.

Catalog No. 239 mailed on request. Write us today.

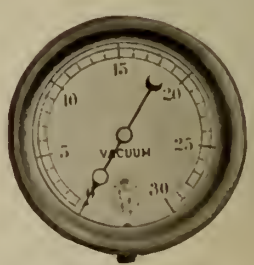
MORRISON'S Steam Goods

"Every Installation a Demonstration of Merit"

BRONZE Y VALVE



VACUUM GAUGE

According to Hoyle!

In times gone by, Hoyle's Book of Rules was the indisputable arbiter to all controversies and troubles arising over the games of those days. Consequently the saying "according to Hoyle" took root.

To-day Morrison's Steam Goods fulfill a purpose not unlike Hoyle's Book of old. For whenever troublesome specialties must be replaced Morrison's Steam Goods are usually chosen. They give long, unfailing service because they are built "according to Hoyle."

Wherever A Trouble-Free Valve Is Needed

Good valves are a very important item in the equipment of a plant.

There is a sense of security in good valves, and there are actual dividends to be realized on savings of labor, time, and costly "shut downs" for repairs or replacements.

Jenkins Valves are good valves. They have proven their merit in every kind of service—in leading factories, plants, buildings—everywhere.

The metal used in their making, whether it be brass, iron or cast steel, is of the very best quality, and is so distributed as to give the valve correct proportion.

Genuine Jenkins Valves are known by the name and the Jenkins Diamond Trade Mark cast on the body—at supply houses everywhere.

Waterous

BRANTFORD, ONTARIO, CANADA

Power & Heating Boilers

Proper steam production is essential in any power mill.

Waterous Boilers enjoy an enviable reputation for easy steaming and for economy in fuel consumption. The correct design of boiler settings is mainly responsible for this.

Whether you are burning coal, screenings, refuse, wood, sawdust, gas or oil, we supply settings that burn it with the least labor and with best economy.

We build Heating Boilers up to 72" x 16', Return Tubular Boilers for power use, up to 165 H.-P.; settings, single or battery, in brick or all-steel.

Garlock Style No. 987
HYDRAULIC DUO PACKING

A combination of rubber cushion and waterproof hydraulic rings. This packing gives excellent service for medium pressures. The reversed cushions make it very effective in handling sandy water, receiving constant lubrication from the waterproof hydraulic rings.

Garlock Hydraulic Duo Packings have been prepared with a thorough understanding of the diverse conditions of hydraulic service.

Among our combinations we have a packing that will solve your problem and succeed where other hydraulic packings have failed. Let us advise you.

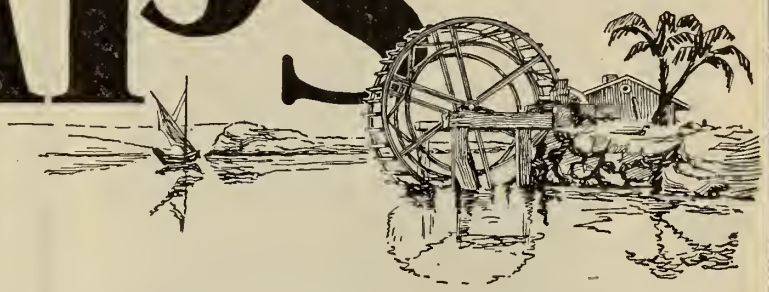
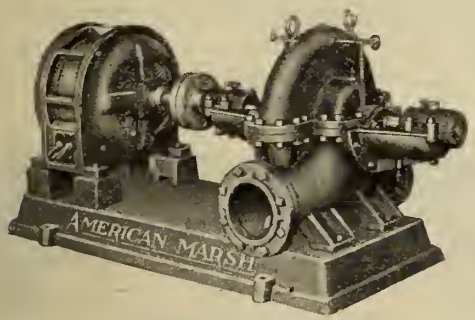
PUMPS



BY use of the ancient Sakieh a pair of oxen could keep ten acres irrigated throughout an Egyptian summer.

The Sakieh, or water wheel, was considerably more efficient than most of the other ancient pumping devices. Made to revolve by beasts of burden, and equipped with an endless chain of buckets, the Sakieh could raise 1,200 gallons of water 24 feet in one hour.

Modern American-Marsh Pumps have a capacity of from 5 to 5,200 gallons per minute. They are especially adapted to the solution of difficult pumping problems. They are made in both single and double suctions, solid and split case patterns.



CENTRIFUGAL PUMPS.

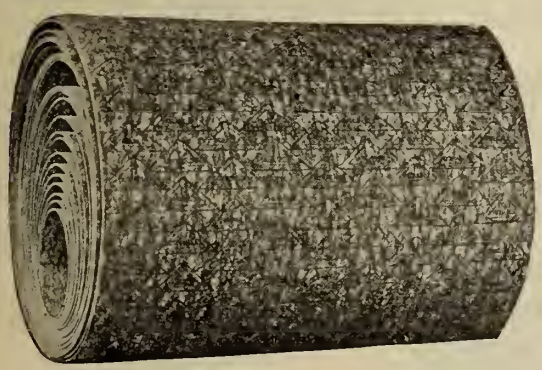
Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.



Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

The Pride of Craftsmanship

Back of every S & B Gauge there is more than mere routine "good workmanship." The pride, as well as the skill, of many veteran gauge makers goes into each instrument.

And therein lies the secret of their reputation—the skill of the craftsman is reflected in the *actual performance* of

S&B Gauges

For Every Condition

Down the whole line, right to the assembling room, there isn't a man but who realizes that in allowing nothing slipshod to pass through his hands, he is carrying out the traditions of this great institution.

It is this loyalty to high ideals that insures to you, in an S & B Gauge, an instrument of the utmost accuracy and durability.

You can't go wrong on an S & B Gauge. It simply *must* give you service. And service in a steam gauge means preservation of human life—exemption from property loss—and low gauge costs. A triple economy.

Other "reasons why" for S & B Gauges are clearly set forth in our Catalog A-33 *Write for a copy today.*

Best in Forty Years

Read below what one of our many satisfied customers has to say about

PLIBRICO JOINTLESS FURNACE LINING

"We have used it continuously for the last three years with the very best of results under fairly severe conditions. Our engineer says it is the best preparation by far of anything in his experience of forty years."

Try it yourself, in front-door arches, side walls, bridge walls, and baffles, and learn of its many money and time saving qualities, the ease of its installation, and its strength..

Our interesting book, L-37, will tell you all about it. Ask for it.

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

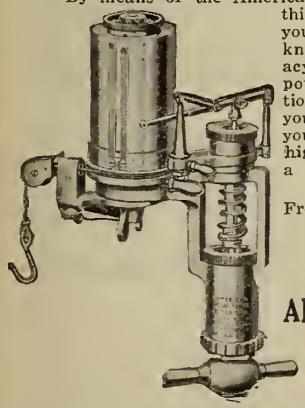
AMERICAN THOMPSON IMPROVED INDICATOR

Successful men in all lines use the brains of others. This is equally true of the engineering profession. You as an engineer will be more successful—more valuable to your employer—if you profit by the ideas and inventions of specialists.

One way to do this is to make a practice of constantly using the American Thompson Improved Indicator.

This indicator—the only flawless instrument of its kind made—is the original Indicator invented by the late J. W. Thompson, an engineer of international fame, and perfected by him after years of tireless experiment. His ability and brains become your ability and brains when you employ the American Thompson Indicator in your profession.

By means of the American Indicator you can know many things about your engine that you have never been able to know before with absolute accuracy. It enables you to conserve power, save fuel, rectify installation errors and prolong the life of your engine. In a word, it makes you an engineering expert of the highest order. And that means a fatter pay envelope.



A Postcard brings our valuable Free Booklet.

New Truths and Old Fallacies

Lubricating Quality—*Continued*

The test of Magnolia Metal at the Brooklyn Navy Yard by the United States Government was made, chiefly, in comparison with White Brass, a tin-zinc mixture, at that time used by the navy, but discontinued after this test.

The engineer officers in charge of test thought that it would also be a good time to try out a babbitt metal of the same composition as Magnolia but made in the conventional way of merely melting together the ingredients, without special foundry and graphite treatment.

The tests of these three metals were made with both water and oil lubrication on a machine with capacity up to 600 lbs. load per square inch.

In the test with water lubrication, which discloses the true intrinsic worth of metals, Magnolia developed a frictional co-efficient as low as 0.00080 and proved to be 200 per cent superior anti-frictionally to the "conventional" babbit and 1,100 per cent. superior anti-frictionally to the White Brass, the latter failing under a comparatively light stress, just as the Genuines did in the test by Doctor Torrey.

In report of this test mention is made of the peculiar property of White Brass in becoming pasty and crumbling when hot. As a result of this test Magnolia was recommended for use in the Steam Engineering Department of the Navy.

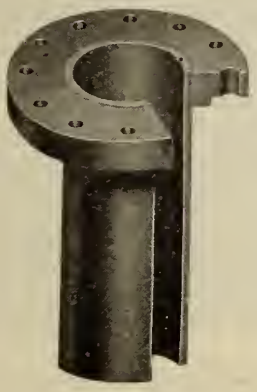
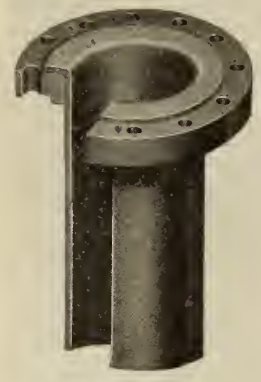
P⌀H FLANGED PIPE JOINTS



SCREWED



P. H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend Lap Joint.

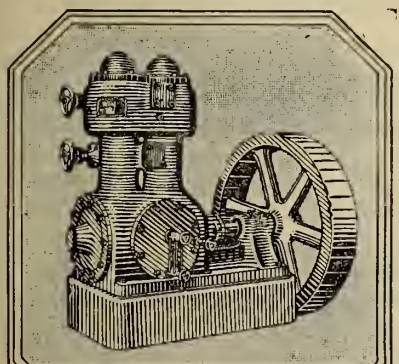
YORK



YORK ENCLOSED MACHINE

RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

The 4-inch Nonpareil Corkboard in the walls of this ice storage is finished with mastic asphalt, ironed on at the factory. The roof and floor insulation are 6 and 5 inches thick, respectively. Independent Ice and Cold Storage Company, Shreveport, La.

Storage for Economy

Of course, an ice-plant can be operated without a permanent storage. But ice storages would not be built if they had not demonstrated that they are profitable. The fact is that an ice-plant without ample storage is operating at very low efficiency, like any other factory that is alternately idle and overloaded.

It is also possible to build an ice storage without insulating it with Nonpareil Corkboard. But it is significant that those plants which have most convincingly demonstrated that the storage of ice is good business *are insulated* with Nonpareil Corkboard. The reason is this: Ice can be stored profitably for long periods provided little refrigeration is required to hold the proper temperature. Now ice does not have to be cooled; all the refrigeration has to do is to remove the heat that leaks in through the construction. The better the insulation the less refrigeration will be used; hence, the quality and quantity of the insulation practically determine the cost of operation.

Ice storages are built for low cost operation; Nonpareil Corkboard is the most *efficient* insulation. They are built for permanence; Nonpareil Corkboard is the most *durable* insulation. They are built for profit; Nonpareil Corkboard is the most *economical* insulation. It is the recognition of these facts by keen-thinking ice manufacturers that accounts for the widespread use of Nonpareil Corkboard in houses like that shown above.

Without charge or obligation the engineering department of this company is at your service. Data, specifications, and estimates on the insulation of ice storages will be gladly furnished. If you are planning to build or extend storage space, don't fail to get the 152-page book, "Nonpareil Corkboard Insulation." It will be sent free on request.

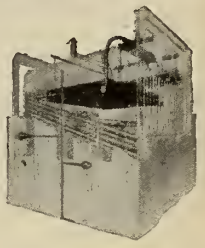
DIAMOND VALV-IN-HEAD SOOT BLOWERS



THE PRINCIPLE OF THE VALV-IN-HEAD SOOT BLOWER is so new and so different that its possibilities can hardly be adequately described.

Take for instance the matter of labor,—the new Diamond head effects a saving of fully 50 p.c. as compared to other types of hand operated units. Note how this is accomplished:

(a) The total time required for blowing is cut squarely in half.

(b) There is no walking back and forth from blower operating chain to valve—a single round trip completes the cycle of operations.

(c) Only one man is required, no matter how large the boiler. (With other types of blower heads two men are customarily employed on large boilers.)

Under these conditions the cost of labor becomes an almost negligible factor in the cost of operating the soot blower.

The saving in steam is just as pronounced, because every bit of steam does effective work in cleaning the boiler. Note how waste is avoided:

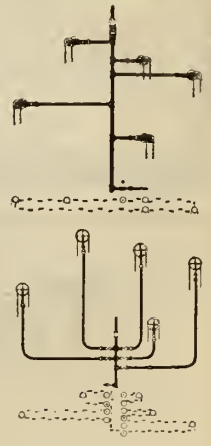
(a) No steam is discharged while the operator is walking.

(b) Steam jets are in rotation throughout the entire blowing period.

(c) Speed of rotation is controlled by gear reduction. No waste of steam occurs as the result of too slow or too rapid operation.

(d) Globe valves, essential to other heads, require many valuable moments to open and close, during which steam is wasted. The instant operation of the Valv-in-Head eliminates losses.

These are only two of eleven important advantages of Diamond Valv-in-Head soot blowers. Others include savings in pipe, valves and fittings, maintenance, gain in cleaning efficiency, etc., etc.
Every boiler needs a mechanical soot blower and you will save money by buying the best. Diamond Valv-in-Head blowers are adapted to all types of water tube boilers. On request our Service Engineer will go over your existing soot blower installation and advise whether it can profitably be replaced with the Diamond Valv-in-Head system. Ask for your copy of Bulletin 287 describing the new blower.



Saving steps saves steam Valv-in-Head means single round trip. No steam while walking. Independent valves mean steps retraced, steam wasted while walking.

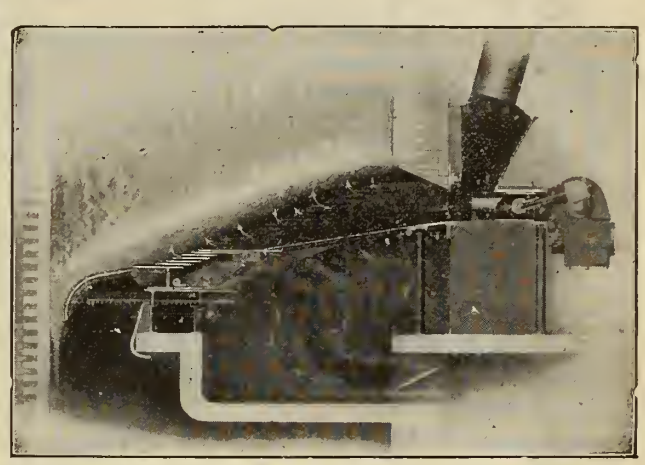
Let Riley Stokers Reduce Your Costs



Cross section through stoker showing automatic operation.

Riley Stokers are always on the job—you can rely on them to be at work every day. They are tireless—working all hours of the day and night—without complaint.

Industrial Plants can cut their operating costs to a minimum by using Riley Underfeed Stokers. Consider the following facts:

RILEY UNDERFEED STOKERS

EFFICIENCY — Boiler tests on Riley Stokers have shown over-all efficiencies of 80 per cent. and higher.

LABOR-SAVING—One or two men can replace ten or twelve required for hand firing. Continuous, automatic discharge of ashes means elimination of drudgery in fire cleaning. Labor for ash handling in a well laid out plant is negligible.

CAPACITY—Capacities of 200 per cent. and more can be obtained over long periods which means fewer boilers with corresponding decrease in investment and maintenance.

COMPLETE COMBUSTION—The underfeed method and moving grates intimately mix the proper amount of air and coal, giving complete combustion.

Catalog H-R-9 sent on request.

COKAL

HAND STOKERS

THE SIGNIFICANCE TO *YOU* OF THE MEMBERSHIP OF

POWER HOUSE

IN THE ASSOCIATED BUSINESS PAPERS, INC.

YOU depend upon Power House for an unbiased and accurate report of all news affecting your business interests.

Probably, too, you give heed to its editorial counsel in many matters of considerable consequence. You have a right, therefore, to know about the policies and principles back of the important service rendered by Power House.

The membership of this publication in The Associated Business Papers, Inc., means that it has achieved an exceptionally high publishing standard, and has subscribed unreservedly to these—

STANDARDS OF PRACTICE

The publisher of a business paper should dedicate his best efforts to the cause of Business and Social Service, and to this end should pledge himself—

1. To consider, first, the interests of the subscriber.
2. To subscribe to and work for truth and honesty in all departments.
3. To eliminate, in so far as possible, his personal opinions from his news columns, but to be a leader of thought in his editorial columns, and to make his criticisms constructive.
4. To refuse to publish "puffs," free reading notices or paid "write-ups"; to keep his reading columns independent of advertising considerations, and to measure all news by this standard: "Is it real news?"
5. To decline any advertisement which has a tendency to mislead or which does not conform to business integrity.
6. To solicit subscriptions and advertising solely upon the merits of the publication.
7. To supply advertisers with full information regarding character and extent of circulation, including detailed circulation statements, subject to proper and authentic verification.
8. To co-operate with all organizations and individuals engaged in creative advertising work.
9. To avoid unfair competition.
10. To determine what is the highest and largest function of the field which he serves, and then to strive in every legitimate way to promote that function.

If you have read the foregoing standards, there is not much left to be said, except to tell you that these principles are *present day realities* and not merely beautiful ideals for future attainment.

The Treatment of Boiler Feed Water

This Article is the Continuation of the Article which Appeared in the Issue of August 5th and Carries the Subject on to Different Methods and Materials

By ROBERT JUNE

IN OUR preceding article we dealt with the nature of the various impurities in boiler feed water, and the operating troubles resulting from them. We have now to consider the various methods in use of treating bad water.

According to our previous outline, the neutralization or elimination of impurities in feed water may be effected by one or more of the following methods.

(b) Blow off.

1. By chemical means.
   (a) Boiler compounds.
   (b) Water softening plants.
2. By mechanical means.
   (a) Tube cleaners.
   (c) Filter plants.
3. By thermal treatment.
   (a) Feed water heaters.
   (b) Distillation plants.

Boiler Compounds

There are a number of boiler compounds in use, but the base of most of these is carbonate of soda, to which caustic soda is sometimes added and occasionally phosphate of soda. In addition materials containing tannin and starch are frequently added, with the object of coating the particles of precipitated matter so as to prevent their cohesion.

The use of boiler compounds is sometimes condemned as thoroughly bad practice, the following contentions being made; that mechanical difficulties prevent the maintenance of proper ratio between the amount of compound used and the volumn of water; that it is very difficult to control the treatment to take care of the changing analysis of the water; that adequate boiler compound treatment is very expensive; that compounds necessitate frequently blowing down the boiler to prevent an accumulation of sludge and sodium salts, which cause foaming and that moreover blowing down must frequently be supplemented by wahing out and occasionally cutting out the boiler completely to remove foreign matter.

Despite these criticisms, boiler compounds still find favor with many practical men, particularly in small boiler plants. When it comes to compounds, a great deal of care and attention must be paid to their selection and use. A great deal depends upon the attitude of the compound manufacturer. If he is willing to sit down and thresh out your problem with you, you may receive satisfactory service at a cost that is not prohibitive.

It is all simply a matter of relation of costs to the results obtained. While there are some compounds on the market which are worthless, and some manufacturers who offer cure alls and do not give satisfactory service, there are other compounds which are reasonably satisfactory and do not involve a large plant investment. Though the weight of evidence is very much against the indiscriminate use of compounds, the fact remains that they are in satisfactory use in many small plants.

Graphite

Graphite has no retarding influence on the formation of scale, but it tends to prevent the scale from adhering firmly to the metal. The particles of graphite simply work through the minute fissures existing in the old scale and gradually penetrate between the scale and the metal. The scale thus loosened may be knocked off or removed with regular cleaning tools with little trouble.

Before starting the use of graphite, the boiler must first be thoroughly turbined. Once removed the scale will not adhere firmly to the metal again as long as the graphite treatment is continued. The graphite also becomes intermixed with new scale as it forms, rendering it soft and friable. With graphite, as with boiler compounds, any boiler using bad water should be blown down a gauge or two every few hours to remove sludge.

Kerosene

Good results in softening scale are sometimes secured through the use of kerosene and other refined petroleum oils. This treatment changes the deposits of lime from a hard scale to a friable material which may be easily removed. If the treatment is to be effective, kerosene should be introduced after the boiler is emptied and washed, and the refilling should be effected from the bottom. If kerosene is fed into the boiler with the feed it may form a non-conducting film over the heating surface.

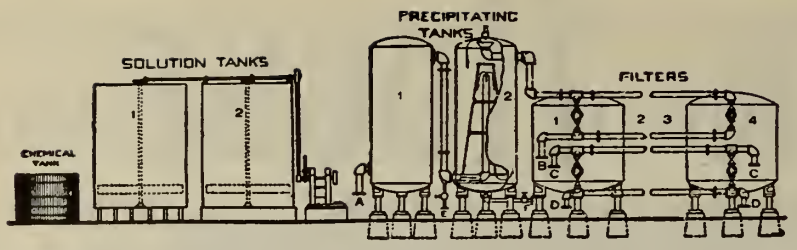
Zinc

While zinc is often introduced into boilers to prevent corrosion and scale formation, it does not as a matter of fact always accomplish this purpose, and it may even aggravate the trouble. The action of zinc is electrolytic, the theory being that a continuous flow of hydrogen is generated over the whole extent of the wet surface of the boiler. It is supposed that the continuous formation of the bubbles of hydrogen insulates the surface of the metal from the scale forming substances. If there is a little of the scale forming element it is precipitated and reduced to mud; if there is considerable, a formed scale is produced which however does not adhere tightly to the surface of the metal and is consequently readily removed.

The zinc is introduced in the boiler where it is suspended in the water in the shape of blocks, slabs or shavings, in a perforated container. In marine practice where zinc is in much greater use than in stationary boilers, it is usual to find zinc slabs 12 inches by 6 inches by 1½ inches in use. One square inch of zinc surface is ordinarily supposed to be sufficient for 50 lbs. of water in the boiler, although as a mater of fact the quantity of zinc used should be in proportion to the hardness of the water. The British Admiralty, who are advocates of zinc, recommend renewing of the slabs when their disintegration reaches a depth of ¼ inch.

Boiler Metal Treatment

A treatment which has in recent years come into quite wide use consists in the application of Peroln. This is a blue viscous non-volatile mineral liquid, which possesses the characteristic of an exceedingly high co-efficient of expansion. The



The Scaife System.

liquid is injected into the boiler in small daily doses. It penetrates the pores and crevices in the scale and comes into direct contact with the metal, where like graphite, it works its way along the steel, eventually forming an insulating coating between the scale and the tubes. The high co-efficient of expansion tends, whenever the boiler is cut in, to loosen any scale which has formed.

Advantages and Disadvantages of Compounds and Metal Treatment

Compounds and metal treatment of the various sorts described above possess the advantage of not requiring an initial investment and of lending themselves very readily to experimentation. In case a given compound or treatment does not work, it may be modified, or another treatment may be tried. The operating costs are also less per gallon of water treated than where special treatment is installed.

The serious disadvantages of compounds and metal treatment are that under favorable conditions all that the most effective of these methods can do is to change the nature of the scale forming material from one which will be precipitated, to one which will be carried in suspension. Frequent blowing off is at all times necessary with consequent heat losses, and as the accumulation of sludge can never be entirely removed while blowing off, so that the boiler is frequently cut in for washing. This puts the boiler out of commission and entails a loss on the investment in the boiler whenever an extra steam generator must be provided to take the place of those cut out for washing. Frequent cutting in and out of the boiler itself is an expensive operation. Taking everything into consideration, compounds and metal treatment are to be recommended for use primarily in small plants. In large plants and in particular where steam must be continuously generated, we must turn to a method of treating the water before it enters the boiler.

Water Softening and Purifying Plants

The treatment of water outside of the boiler through the medium of water softening plants is accomplished by either one or two processes, known as the intermittent and the continuous.

Cold process plants are used primarily where water is required in very large quantities. Hot process plants are commonly used where exhaust steam is available for heating the water.

With the continuous system, the water to be treated flows to the softener in a continuous stream, while with the intermittent system it is treated in batches. Successful treatment in either case requires the proper proportioning of water and chemicals, through miring and agitation, and the allowance of sufficient time for the reaction to take place so that all of the sludge may be removed from the water.

Lime and soda are the principal ingredients used in these processes, where sulphates of lime and magnesia are contained in the water, together with such quantities of carbonic acid or bicarbonate present as to impair the acton of the soda. This is quite a common condition. The sulphates of lime and magnesia are broken down by the soda, and as much lime is added as is required to take up the carbonic acid not absorbed in the soda reaction.

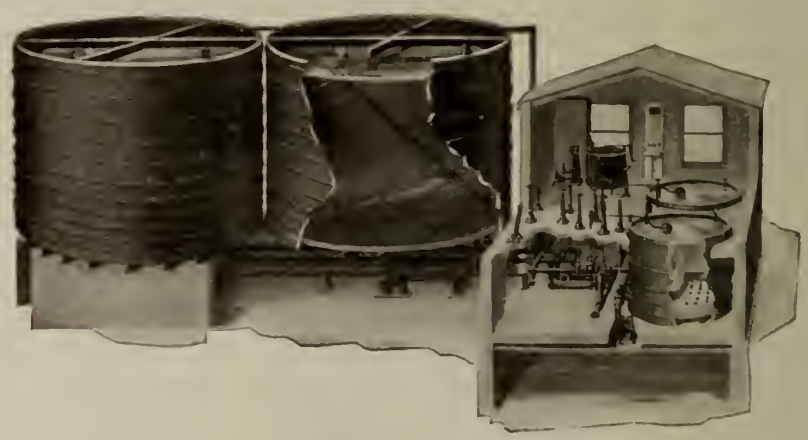
Before dealing with the apparatus, it may be well to describe simply the chemical tests of the treated water which will enable us to interpret intelligently the results being obtained. Alkalinity, hardness, and causticity, should, when the water is properly treated, be in the approximate relation of six, five and four. The use of too much lime will result in causticity being nearly equal to alkalinity. The use of too little lime will result in a causticity amounting to only about half the alkalinity. If too much soda is used, hardness, which should not be more than two points less than alkalinity, will be decreased below this amount, and the alkalinity correspondingly increased. Too little soda means an increase in hardness and a decrease in alkalinity. The tests are as follows:

Alkalinity: Provide a standard solution of sulphuric acid. But sufficient methyl orange in 50 cc. of the water being tested to color it. Measure out a quantity of the acid solution and put it in a drop at a time. As the solution is added the mixture will begin to turn red. Shake the mixture and the redness will tend to disappear. Put in more acid and continue to shake. As the critical point is approached the red will disappear more slowly. When the red color is permanent, the critical point has been reached. 1/10 cc. of the acid solution is equivalent to one degree of alkalinity.

Causticity: Use the same standard solution of sulphuric acid. To 50 cc. of the treated water add one drop of phenolphthalein dissolved in alcohol. This is to give the water a pinkish color. Put in a drop at a time of the acid solution, shaking after each addition. The critical point is reached when the color entirely disappears. 1/10 cc. of acid solution is equivalent to one degree of causticity.

Hadness: Procure a standard soap solution. To 100 cc. of the water to be treated, add 1 cc. of the soap solution, and shake thoroughly. If the soap bubbles disappear, add another cc. of the soap solution. Enough of the soap solution must be added to make a permanent lather or foam from which the soap bubbles will not disappear after the shaking is discontinued.

To determine the excess of lime, add a small amount of silver nitrate to the treated water. If a milky solution is formed the lime is not in excess. If the mixture turns brown there is too much lime.



The We-Fu-Go System.

The Scaife System

In the Scaife system which is a continuous one, the feed water first enters the heater where it is brought to a temperature or 200 to 210 deg. F. As a portion of the CO_2 is driven off by the heat, carbonates of lime and magnesium are precipitated and deposited in removable pans inside the heater.

The system consists of a number of precipitating tanks with one or more pressure filters, all built to operate under boiler pressure, and the necessary solution tanks, pumps and controlling devices. The precipitating tanks may be either horizontal or vertical, depending upon the space available. The solution

tanks hold sufficient quantity of chemicals to operate the plant from eight to twelve hours. The small pumps deliver this solution to the precipitating tanks, which are so constructed that the water is kept moving and the chemicals are intimately and thoroughly mixed. In this manner acids are neutralized and the scale forming substances are changed to insolubles which sink in the form of heavy precipitates to the bottom of the tank, whence they are readily removed. From the precipitating tanks the mixture moves to the filters where the lighter substances in suspension are effectively removed.

We-Fu-Go System

The We-Fu-Go is an intermittent process. The system consists essentially of one or more solution tanks from which the chemicals are taken, and one or more settling tanks into which the water to be treated and the chemicals are introduced, and of one or more filters. A thorough mixture of the chemicals and the water in the settling tanks is effected by the use of mechanically operated paddles located near the bottom of the tank. The softened water is taken out of the tank by means of a hinged floating outlet pipe, arranged to rise and fall with the level of the water, so that the water is always drawn from the top, where there is least amount of sludge. From the settling tanks the water flows by gravity into the filters, which remove all remaining solid matter which has not dropped to the bottom of the settling tank.

From the filter the purified water again flows by gravity into the clear water storage reservoir from which it is pumped to the open heater and thence to the boiler. As a general rule duplicate systems are employed, so that while one tank is being treated and settled, the other is supplying finished water.

It should be understood of course that the above descriptions of the Scaife and We-Fu-Go systems are general in nature, as modifications of both of these systems are often made to meet special conditions.

Our next article will deal with the operation and maintenance of the water softening plants described in this article and we will also take up in detail the design, construction and operation of Zeolite plants.

BRUSH AND COMMUTATOR TROUBLES

Not only should great care be given to brushes when first installed, but they should also receive careful attention throughout their life. Brushes, holders, and commutator should be cleaned thoroughly and regularly, so that it will be certain that each brush shall have free play in its box, and that the pressure arm also shall have free movement. Such attention to detail may mean the difference between good and poor brush operation. Usually when brushes are operating poorly they are shouldered with the entire blame irrespective of conditions. There are conditions, however, under which any brush will operate poorly. One very common fault is copper-picking, and usually this is carried by other reasons than improper brushes. Often this fault, is exceedingly difficult to correct. Occasionally, brushes pick copper immediately after being first installed, while their surfaces are still freshly sandpapered and the commutator surface is raw. Under these circumstances brushes pick up copper that is liberated by mechanical abrasion. If this be the case, the trouble can be overcome by carefully wiping off each brush from time to time until the contact surfaces are polished. However, in most instances copper-picking is caused by circulating currents in the faces of the brushes. Machines with interpoles or pole-face windings are much less liable to copper-picking than the non-interpole machines On the latter type of machine a better brush position for the required load conditions may effect an improvement in this fault. Often poorly sanded brushes, with resultant small areas of contact, cause undue circulating currents to flow, resulting in extreme local heating, which in turn burns off the particles of copper from the commutator bars, and these particles are caught by the brush surfaces. Sometimes, under certain conditions brushes of only one polarity are affected—usually the positive brushes on a generator or negative brushes on a motor; that is, copper is carried along with current flow from copper to carbon. After all other efforts fail an improvement may be made by changing the grade of the brushes, this change having the effect of altering the amount of circulating current or acting as a damper to the passing of copper particles from commutator to brush.

Ridging or grooving of commutators is another fault that is distressing to the operator who takes pride in keeping his machines in the best condition. The location of the brushes on the commutator plays a great part in correcting this fault. The method of staggering brushes around the commutator which gives the best results is to have the staggering done in pairs of studs rather than alternately. The latter method permits the positive brushes to track on one part of the commutator, while the negative track on another. It is found that usually the negative brushes on a motor wear the commutator much more rapidly than the positive; hence, if all negative brushes are permited to track each other, grooves will form, leaving ridges under the positive brushes. Excessive grooving may be caused by a too-abrasive brush, by too much spring tension, which should be only great enough to keep intimate contact between brush and commutator, or by improper brush position or commutating-pole adjustment permitting undue circulating currents to be present in the face of the brush, causing excessive local heating, which burns away the copper.

Frequently operators apply lubricant to the commutator in an endeavour to stop the grooving action. This practice is not advisable, as the lubricant is liable to gum on the commutator, causing varying contact drop and position of the brush. For the same reasons the use of impregnated brushes is not recommended.

Chattering of brushes is another distressing fault, which is caused by using an improper grade of brush, by brushes operating at the wrong angle, by the commutator surface being uneven or out of "true," or by high mica. Trailing brushes work best at 15 degrees or less, while leading brushes, reaction type, should have an angle between 30 degrees and 40 degrees. (The angles as here used are the degrees of tilt from the radial position.) It will not be necessary to elaborate on uneven or out-of-true commutator surfaces, as all are familiar with this phase of trouble. However, high mica may be the cause of trouble when least expected. Even after a commutator is newly turned down, the mica may be slightly high because the machinist has not had the proper edge on the turning tool, and consequently the copper has been cut away more than the mica. A good stoning or strenuous attack with carborundum cloth when the machine is cold will be necessary to take down the mica. Chattering is often present on a commutator having surface speed too high for the particular grade of brush used, hence it is urged that operators keep within the limits of speed as outlined by the brush manufacturers.—"Electrical World."

WATERPOWER DEVELOPMENT IN JAPAN

"Japan is pushing work on hydro-electric development as the demand for power in the larger cities as well as smaller villages is far in excess of the supply available," according to Stephen Q. Hayes, a special electrical engineer of the Westinghouse Electric & Manufacturing Company, who just returned from a six months' tour of Australia and Japan, where he made a special study of business conditions. Tokyo and Yokohama, near the eastern end of the main island, are supplied with power at fifty cycles from many hydro-electric plants and there is an electrified section of the railway between these two cities with multiple unit trains every ten or fifteen minutes.

Near the middle of the main island, about 350 miles from Yokohama and Tokyo, are the large manufacturing cities of Kyoto, Osaka and Kobe. These are fed by numerous transmission systems operating at sixty cycles. Some of the most important hydro-electric generating stations are located about half way between the two groups of cities and some interesting problems are involved in making some of these stations suitable for feeding fifty cycle current to Tokyo and Yokohama and sixty cycle current to Kyoto, Osaka and Kobe.

What Pulled The Head In? Is This A Collapse?

An Accident Occurs, and the Question of What Can be Called a Collapse is Brought Up—Can a Place Collapse When the Pressure Tends to Blow It Out

BOILER insurance companies sometimes have claims to settle which are more or less controversial, by which we mean that the damage is not of a nature that leaves no room for doubt, as to the liability. A case of this kind has been brought to our notice recently, and we feel that it gives an opportunity for some readers to do a little thinking and to put their opinions on record. The case is as follows:—

A boiler of the horizontal return tube type, insured against explosion, rupture or collapse, which is the general way in which these policies are written, sustained a severe bulge in the furnace sheet. The boiler had been standing under banked fires during the night, and the bulge occurred while the fires were being brightened up in the morning ready for the factory to start. The engineer was informed on his arrival at the plant that the gauge glass was full, but instead of that, he found the boiler was without water, and the plate over the fire bulged for one third of the circumference and for about six feet in length. The fires were drawn and the boiler pressure released, and when the boiler was sufficiently cooled down an examination was made. The plate over the fire was then discovered to be bulged for one third of its circumference, and about six feet in length, while the front end plate had been drawn in at the bottom, to the extent of about 1⅛ inches. The owners of the boiler claimed that this drawing in of the front end plate was a collapse within the meaning of the policy. The whole of the case then as regards the front end plate hinged on the cause of this drawing in. Could this deformation or bending in of the tube plate be considered a collapse? A collapse is understood to mean a crushing of the plate due to the surrounding boiler pressure, as in the case of a circular furnace tube or a fire tube in a H.R.T. boiler. It can be clearly understood from the construction of a H.R.T. boiler that no external pressure could so bulge inwards the front tube plate. For the tube to bend in this manner it must do so against the internal boiler pressure, which tends to keep the plate in shape, or otherwise bend it outwards.

The lower part of the front end plate was rigidly supported by the tubes and also by the two direct stays underneath the tubes, and this support was entirely independent of the support given by the attachment of the end plate to the first circumferential sheet. The lower tubes were actually protruding through the plate from ½ inch to 1 inch after the deformation took place.

Presuming that the end plate had no support such as tubes and stays, it would have a resistance to bending due to its sectional area, and in order to remain in equilibrium this amount of resistance would have to be equal to the bending moment exerted upon it. Owing to the presence of the stays and tubes however, the resistance to bending would be very much greater than if the plate was unsupported. We must however, remember that the temperature of the end plate would be much higher than normal, and on this account the support accorded by the tubes and stays can be assumed to be reduced about 50%, which is perhaps a liberal allowance. We have then the fact that we have a plate or if we consider a small portion of the head, a strip or bar supported at the ends, or fixed at the ends and uniformly loaded by the pressure in the boiler. The tendency then would undoubtedly be to force the plate outwards. However, the plate undoubtedly bulged inwards. We must then consider if it was possible for the furnace plate in bulging to exert a force sufficient to draw the head in against the supporting pressure of the steam in the boiler and the tubes. The resistance of the metal is of course lessened by the temperature, and we have no means of knowing what the temperature amounted to. The force exerted on the furnace plate by the boiler pressure was expended in deforming the metal, and here again we are not sufficiently supplied with data. If the metal was bulged outwards without any contraction of area, as occurs in a testing machine then some other part of the boiler would have been deformed to allow for the deformation of the furnace plate. If however, the bulged portion suffered a contraction of area, there need be no deformation of any part except that locally affected.

On the other hand, could there have been a force exerted when the metal was cooling and contracting to cause the deformation of the end plate? This again would depend on how far the overheating extended and to what extent. If the bulge in the furnace plate had occurred without any contraction of area, and the overheating extended in gradually diminishing temperature from the centre of the bulge to the end plate, it is natural to assume that the less heated parts would cool first, and in cooling draw in the heated part, that is the deeper part of the bulge and this is more readily assumed because the pressure in the boiler would be exerting less force, due to a lowering of pressure. There would then be no tendency to draw in the head.

View of boiler showing bulges.—Tubes and stays removed.

Supposing that when the boiler was in normal working order, the direct stays were in a state of tension, not only due to the pressure in the boiler, but a certain initial tension placed upon them when setting them up in the first place. Now suppose when the heating took place, this extended to the front end plate in some degree so as to lessen its power of resistance. The bulging takes place in the furnace plate, and the stays not being in compression have no tendency to resist the drawing in of the head to conform to the altered shape of the boiler. The

heating of the end plate has we assume, lessened the resistance due to the tubes. The bulging of the plate, coupl-with the pulll of the stays in tension, may have been sufficient to overcome the pressure of the steam on the small area which bent inwards. Can this be assumed to be a collapse? This is an interesting question. The dimensions of the boiler were 66 inches diameter, by 16 feet long. The shell plates were 7-16ths, while the head was ½ inch tubes. The bulging of the plate, coupled was 4 inches deep at its extreme point, while the indent in the head was 1 1-8th inches at its extreme depth. The pressure in the boiler was 125lb. per square inch. The stays in the boiler under the tubes were 1¾ inches in diameter, while the tubes were 3 inches diameter.

This case has been settled, but it is quite possible that other cases of a like nature may occur, and it is therefore of interest to see what arguments can be brought forward by engineers to confirm or oppose the claim of collapse. Suppose such a thing should happen to a boiler that you had charge of, and it was up to you to formulate the claim to the insurance company. How would you meet the claims of the company's engineers, or how would you substantiate your own claims?

WELL KNOWN ENGINEER DIES

Angus Sinclair, who was well known as a civil engineer and railway contractor, died a few days ago in Toronto. Mr Sinclair built many of the railway lines on the Canadian Pacific and Canadian Northern systems, and was well known in Chatham, N. B., where he was born in 1849. Since that time he passed through many experiences. In 1869 he joined the staff of the Intercolonial Railway and remained until 1875, when he supervised the completion of the road from Matapedia to Bathurst. He came to Ontario in 1875, joined the staff of the C. P. R. at Port Arthur under the late Samuel Hazelwood in 1875 and remained in that district until 1878, when he abandoned engineering for contracting, and continued on the C. P. R. as a contractor until the road was completed.

He built a section of the C. P. R. east of Toronto, and in partnership with William Doheny constructed the road from Thamesville to Windsor for the C. P. R. Later. in partnership with the late Allen R. I. McDonnell, he constructed 50 miles of C. P. R. short line through Maine, built a portion of Walkerville railway and a section of the Maine Central Cystem, from north Stratford to Hazen Junction in Vermont. He was continuously employed on the C. N. R. System since 1898, during which time he has built from Point Tupper to Broad Cove, B. C., from Halifax to Mahone Bay and Middleton to Victoria Beach, N. S. He returned to Ontario in 1903, and has since built or completed from Toronto to Ruel and from Capreol Junction to Pembroke, 240 miles. He was also engaged in completing the excavation of the open work of Mount Royal Tunnel through the City of Montreal.

OTTAWA LODGE NO 6 C.A.S.E.

An open meeting of the above lodge was held on Aug., 25th in the Trade and Commerce Hall, Wellington St. The meeting was very largely attended and the audience heard a very entertaining from Mr. C. I. Grierson, lecturer and demonstrator of the Imperial Oil Co. Toronto, illustrated by moving pictures. The lecture was given by the courtesy of Major A. E. Oliver, manager of the Imperial Oil Co. The lecture explained and illustrated the winning of petroleum from the earth, and its subsequent distillation and separation into the various lighter volatile liquids, and lubricating oils. The handling of the finished product and shipping into tank cars and tank steamers was illustrated. Probably the most interesting part of the lecture to the engineer was that dealing with ture to the enginer was that dealing with the various oils used for lubricating bearings, their use and abuse. Mr. Greirson who handled his subject with great clarity, had a lot of questions to answer on this part of the lecture.

Ottawa Lodge has been giving a series of open metings which have attracted a lot of attention. Since the convention the Lodge has added no less than fifteen new members to their number, and have great hopes of doubling their membership in the next few months. The president is Mr. J. J. Sullivan, and the recording secretary Mr. R. E. Rodney, 15 Lorne Avenue Ottawa.

TORONTO LODGE NO. 1 C. A. S. E.

Mr. S. G. Hall, president of the Toronto No. 1 C. A. S. E., has recently left town to take up a position in Newmarket, which prevented him from giving the attention he deemed necessary to the first position in the lodge. Mr. Hall therefore resigned the office, and at a recent meeting Mr. Truelove was unanimously elected as President.

EXHIBITION NOTES

The Dominion Belting Co.

are showing a complete line of conveyor and transmission belting. This is the well-known Maple leaf cotton stitch belting. Belt fasteners, belt dressing and other supplies are also displayed. E. Kinrade is in charge.

WATER POWER DEVELOPMENT IN JAPAN

Continued from page 23

As the demand for light and power in the large cities is so greatly in excess of the available supply, rates are high and the distributing companies have not encouraged the use of electric heating appliances and household utensils. When the contemplated extensions to the power companies systems are completed in the next few years, there will probably be a wonderful market for electric cooking and heating appliances and labor saving devices.

The English Electric Co., Limited of Great Britain, the largest manufacturer of electrical equipment and machinery in the British Empire is associated with the English Electric Company of Canada, Limited. The Canadian Company is associated with and holds the exclusive manufacturing rights in perpetuity for the English Company; having use of all their patents, designs, processes, etc.

The entire undertaking of the Canadian Crocker-Wheeler Company, Ltd, of St. Catharines has been acquired so that all the valuable patents and designs of this Company are available.

PERSONAL

E. D. Kilburn, Vice-President and General Manager of the Westinghouse Electric International Company has left New York for a trip to Mexico. While there Mr. Kilburn will make a survey of general business conditions looking forward to considerable expansion in the electrical industry in that country.

Owing to the growth of business in China, the Westinghouse Electric International Company has opened on office in Shanghai. This office will have eventually several branches throughout the country in order to adequately handle inquiries and negotiations for electrical equipment. J. D. Birrell, who has long been engaged in business in the Far East, is the manager of the new office.

MAKING WOOD FIREPROOF

Some recent technical notes from the Forest Products Laboratory state that progress has been made in the preparation of fire retarding paints as the most practical means of making small amounts of wood somewhat fire resistant. Older methods of impregnating the wood with chemicals under pressure or means of keeping it moist are usually too expensive for small projects although they are more effective. Ordinary white wash or calsomine has proved to be as satisfactory as any other type of paint. A coat of calsomine will not prevent the burning of the wood if exposed continuously to great heat but it does materially decrease the danger of a blaze spreading from sparks, cigarettes, and other small sources of fire. Calsomine is naturally best suited to inside uses. For outside work the Laboratory has developed a coat which consists of zinc borate and chrome green ground in linseed oil. This paint after three years of exposure to the weather has retained its fire resisting properties.

The Application of Oil Fuel to Steam Boilers

The Following Notes Are the Result of the Experience Gained by Members of the Manchester Steam Users Association During the Recent Coal Strike in England—These Will be Found Interesting to Canadian Readers

DURING the recent coal stoppage we made observation of a number of typical oil firing installations and it may be of service or interest to our members to record briefly our impressions.

The types of apparatus in use may be divided into two classes which differ widely in their various features, viz.:

(a) The Pressure Jet System.

(b) The Steam or Air Jet System.

Class (a). The oil is atomised by pumping it under pressure through specially formed burners from which it issues with a whirling motion at high velocity.

The atomising is generally better than in the steam or air jet system, and combustion may be almost perfect in this type, but the installation, involving a pumping set and special furnace fronts, etc., is, of course, considerably more costly than Class (b) apparatus.

Class (b) includes those burners in which the oil is "atomised" by steam. This class is important by reason of its extensive adoption as a more or less temporary measure to assist members to keep their works going with little or no coal, and its advantage is its comparative cheapness. Many simple oil sprayers are in use, with a small oil tank on the boiler top and perhaps a larger storage tank in a safe place conveniently near to the boiler, fitted rapidly and at trifling cost. They are quite effective and have assisted many of our members to keep going, but there is no doubt these "burners" are very wasteful, the oil being sprayed rather than atomised, with the result that globules of oil of appreciable size are thrown off. These globules are too large to be burned at once, and since the temperature of the flame falls rapidly there is no chance of complete combustion beyond the region of the flame and a large percentage of the oil is wasted. In one case we noted, a cross tube Vertical Boiler the weight of first class fuel oil being used was at least as great as that of the very poor coal previously used for the same duty. A little brickwork in the firebox greatly improved the result, however.

For use of compressed air as atomising agent the burners are similar to those used for steam atomising, but compressed air has not been extensively used for steam boilers, being more suitable for certain process furnaces (metallurgical furnaces, etc.). An objection to air atomisation for boilers is that the provision of a compressed air supply is less convenient and more costly generally than steam, whilst the system is less efficient than Class (a),

There are, however, several high-class burners on the market for the use of steam as the "atomising" agent, which have been put forward as permanent apparatus and we have seen practically perfect flames from steam burners (about 5 ft. to 6 ft. long and say 1½ ft. diameter in a circular furnace, yellowish white generally, and inclined to a reddish color at the tip). Most of them that we have seen, however, have a strong tendency to the "sparking" or blowing through of globules of unburnt oil referred to. This tendency is more marked when using heavy oils and is reduced where the oil is well warmed and the atomising steam superheated sufficiently to prevent condensation at the burner. It is to be noted that in the burning of oil more water is formed in the flue gases than with coal, and steam for atomising will still further increase it, raising the dew point in the flue gases. It therefore becomes necessary to see that the water entering the fuel economiser, where such is fitted, is kept at the proper temperature to prevent "dewing" on the economiser piper and consequent wasting of the latter. About 120° F. will usually be found sufficient.

The best of these steam atomising burners give very good evaporation results, but cannot compare favorably in oil consumption with the Pressure Jet type.

In most makeshift oil burning arrangements the firebars are not removed and are usually covered with burning coal or with firebrick. It is almost impossible for coal to burn well under these conditions for it is impossible to supply the necessary excess air over the bars. Probably the better plan is to burn the coal in one furnace and the oil in another. Firegrates covered with brick are also a disadvantage for they reduce the volume of the combustion space and force the flame against the furnace plate where its combustion is killed. For burning oil alone it is much better to remove the firebars, the size of the available furnace or combustion space being an important factor. Flames which strike the heating surfaces are cooled rapidly and their combustion is incomplete. Much excess air has then to be introduced and much heat is carried up the chimney. Brick combustion chambers of watertube boilers offer a great advantage from a calorific point of view. Thus in a recent trial with a Stirling boiler the waste gas temperature dropped from about 600° F. with coal to about 450° F. with oil. This was due to the more perfect combustion and as it was necessarily accompanied by a reduced air supply a double gain was effected. It was, of course, accompanied by a high flame temperature which was so intense that after four days working about 14 inches of fire brick had been destroyed.

Fuel Oils

Speaking generally, the steam or air atomisers are more successful with the lighter fuel oils than with heavy oils and the "pressure" systems deal successfully with either light or heavy oils. We find that it is difficult to avoid drip from the steam or air burners using the heavier oils, and at the same time good atomisation is difficult, and commonly, a steam burner which will successfully deal with light oil will be very unsatisfactory with heavy oil at a safe temperature. In warming the oil for use in open tanks, etc., care must be taken to keep below the flash point of the particular oil used, which should be ascertained from the oil vendors or by test. If heated too highly valuable fuel is wasted and there is danger of fire. We find about 130°—140° F. generally suitable for the ordinary gravitation apparatus, with steam or air atomisation, but much higher temperatures (200° F. and over) are usual when dealing with heavy oils in the Pressure systems in which the principal heating is done under pressure.

It is necessary to clean out the oil supply system occasionally and commonly the pumping units are supplied in duplicate for convenience in doing this. It is sometimes inconvenient to stop for "steaming out" when there is no duplicate apparatus, and in that case the system can be kept clear by using light oil for a short time. The heater temperature need not be so high as for heavy oil, 130° F. or thereabouts being generally suitable.

Much alarm has been expressed about a possible injurious effect of the blow pipe action of an oil flame. Experience is as yet limited but no case has presented itself of serious trouble due to this cause and it is doubtful whether a long oil flame in a cylindrical furnace has so high a temperature as sometimes exists in a forced-draught coal fire just above the line of firebars. In fact, long oil flames are, as a rule, due to imperfect atomising, a jet of oil being carried straight to its destination with only a poor chance of perfect combustion. Such a flame would be relatively cool and could do no harm unless, of course, the furnace is covered with scale or grease.

Flue Gas Explosions

Flue gas explosions are more common with oil fuel than with coal, es-

pecially with the steam or air-jet type, and a few words on the subject may be useful.

A mixture of atomised oil and air is explosive and it is important that the oil should be burned as soon as sprayed or atomised. In the event of a flame failing and the oil continuing to flow unburnt there would soon be a considerable volume of explosive gas in the flue, which would explode on reaching ignition temperature. We would suggest that two burners in one furnace are preferable to one larger one—the likelihood of both failing together is much less than that of a single one failing. Further, the range of boiler duty is greater and a better average mixture of oil and air can be maintained in a furnace having a number of burners than where there is only one. There are other causes of flue gas explosions, for instance, unburnt oil in the flues where it will vaporise, perhaps while the boiler is at rest during the night, to explode when the boiler re-starts work.

To avoid these risks, the flame should be kept under constant observation, and the flue dampers opened wide before lighting up for sufficiently long to ensure that the flues will be clear of gas. Should it be found that a flame has failed and oil vapor is passing unburnt into the flues, the oil should be shut off until the flues are clear, before relighting. Any oil leakage is of course objectionable and may be dangerous; in one case oil found its way into the boiler side flue from a leaky tank, resulting in a gas explosion which caused serious damage.

In boilers with high flues and the openings at the bottom (as Stirling type, etc.), we think it desirable to provide for the ventilation of the upper parts, as for instance by a small pipe to the chimney.

The sudden cooling of boilers or brickwork should be avoided; and we would mention in particular that Silica firebrick, which resists high temperatures, is apt to crack if cooled suddenly. Hence when shutting down a boiler having silica brickwork it is necessary to keep the air-admission openings closed and allow the firebrick work to cool gradually.

Regulation of boiler duty should be effected by adjusting the flow of oil and the air admission. For good results there should be a light grey smoke at the chimney top. Complete absence of smoke usually means inefficiency through too much air whilst dense black or yellow smoke means too little air or bad atomising of the oil.

It is convenient to regulate the air admission at the furnaces and in many oil plants, including all the Pressure Jet Systems, this is specially provided for. Flue dampers must not be closed whilst the boiler is working or firemen may be burned by "backfiring"—these dampers may be removed altogether.

Fuel Values Compared

In considering the question of adopting oil as a permanency instead of coal the following questions should be examined:

Calorific value and price of coal available compared with calorific value and price of oil available.

Cost of installation of oil plant, including storage tanks, etc.

Saving in labor and/or machinery for coal and ash handling.

Value of freedom from coal and ash dust in the particular works under consideration.

The fluctuations in boiler performance due to varying conditions of the (coal) fire and to necessary opening of firedoors periodically for charging and cleaning the fires are considerations which weigh in favor of oil firing.

At present of course prices of coal are unstable and considerable fluctuations may be expected. The price of oil also may vary considerably, to say nothing of supplies, and before deciding to change to oil permanently, where fuel costs are of first-class importance, it will be well to await the settling of prices, etc.

If members will let us know the average percentage of ash in their coal, and pare the same with fuel oil as rgards heating value and price. Appended is a comparison of values (approximate) of several kinds of coal, etc., with oil fuel of given calorific value and price.

Taking as a standard, oil £5 per ton.
Waste gases from boiler 660° F.
From economiser 460° F.
Temperature of atmosphere 60°.
Radiation 15 per cent. with ordinary coal, say 2000 B.Th.U. per pound.

	B.Th.U.	%	Price
Boiler	14380	78	100s.
Boiler and economiser	15090	82	100s.

Oil of 18500 B.Th.U. Assume perfect combustion.
Waste gases 15 times weight of oil.

	B.Th.U.	%	Price
Oil of 18500 B.Th.U. Inefficiently burnt.			
Boiler	11500	62	80s.
Boiler and economiser	12100	65	80s.

Subtract cost of steam jets or oil pumps and add saving in labor.
Coal. Nixon's navigation of 15000 B.Th.U.
Waste gases weight 20 time carbon weight.
Ash and moisture 4 per cent.

	B.Th.U.	%	Price
Boiler	10250	68	70s.
Boiler and economiser	11160	74	75s.

Subtract cost of handling ashes.
Coke of 10000 B.Th.U.
Waste gases weight 20 times carbon weight.
Ash and moisture 30 per cent.

	B.Th.U.	%	Price
Boiler	6020	60	42s.
Boiler and economiser	6680	67	44s.

Subtract cost of steam jets and of handling 20 per cent. ashes.
Ordinary coal of 13500 B.Th.U. Hand fired.
Waste gases weigh 25 times carbon weight.

	B.Th.U.	%	Price
Boiler	8140	60	57s.
Boiler and economiser	9260	69	61s.

Subtract removal of 5 per cent. ashes.
Inferior coal of 10000 B.Th.U. Hand fired.
Waste gases weight 25 times carbon weight.

	B.Th.U.	%	Price
Boiler	5180	51	36s.
Boiler and economiser	6120	61	40s.

Subtract removal of 20 per cent. ashes.
Add or subtract from estimated "inferior" coal values as follows per 1000 B.Th.U.

	B.Th.U.	%	Price
Approximately	880	2.0	6s. 3d.
	930	2.5	11s. 6d.

A few words of explanation will be useful as indicating how the figures are arrived at.

Column 1, headed "B.Th.U." gives the heat units actually utilized by the boiler, and by boiler and economiser, under the stated conditions, representing Calorific values, minus radiation, minum heat in waste gases.

Column 2, headed "Per cent." gives the Thermal efficiency.

Column 3, headed "Price," gives the value of the fuel compared with oil at 100s.

Taking coke of 10000 B.Th.U. for example, we have, per pound:

Carbon (or combustible) weight 0.7 lbs.
Waste gases 0.7×20 14 lbs.
Heat lost per 1° F. excess temperature of waste gases above ordinary temperature $=14 \times 0.236$ B.Th.U. (.236 is specific heat of the waste gases.)
for 600° (boiler alone) .. 1980 B.Th.U.
400° (Boiler and economiser) . . . . . 1320 B.Th.U.
Heat lost by radiation 2000 B.Th.U.
Heat utilized by boiler $=10000-2000-1980=6020$ B.Th.U.
Heat utilized by boiler and economiser $10000-2000-1320-6680$ B.Th.U.
Value of fuel compared with oil at 100s. $= 6020 \times 100$s. $=42$s.

(Boiler alone) 14370
Value of fuel compared with oil at 100s. $= 6680 \times 100$s. $=44$s.

(Boiler & economiser) 15090

When the cost of steam jets and of handling ashes, etc., is taken into account the value of the (solid) fuel is naturally less than these figures as compared with oil.

Some Principles of Oil Burning

In view of the permanency of a number of oil-firing installations, it has been desirable to add a few words on the leading principles of oil combustion. The Wells burner and similar ones produce a gas flame by forcing oil through a coil of pipe exposed to the temperature of the flame, and the resulting oil vapor emerging out of a suitable burner induces a draft of air in which it burns. This burner does not seem to have been used for boiler firing, possibly because the available oil fuel is thick and would therefore "crack" if exposed to a high temperature and the resulting carbonaceous residue would doubtless soon choke the pipes.

In a close approach to this type of burner, the oil is heated by steam to near its boiling point. If, in addition, superheated steam be used for atomising the oil, it is probably gasified as it leaves the burner. In other cases the globules of oil are so infinitesimally small that when mixed with air they practically constitute an explosive mixture which ignites when heated.

The smallness of the oil globules is an important matter as will be seen from the following consideration. Even "large" globules are of small dimensions, say at most 1/1000 inch diameter. They, therefore, travel with the air in which they burn. They do not move across their surrounding air and therefore do not shed their mantles of products of combustion. These consist of an outer shell of carbonic acid gas with an excess of air, inside of this one is a shell of CO_2 and nitrogen but no oxygen, inside of this one there will be a shell of carbon monoxide and perhaps oil vapor, which shell surrounds a kernel of cracked oil, a carbonaceous spongy mass which is difficult to ignite. Some sort of mixing will take place in the body of the flame, but as the oxygen percentage is now much reduced, re-ignition and further combustion will not take place unless the flame is very hot. Now the larger the oil globules the more imperfect will be what might be called the first combustion and the more imperfect will be the secondary combustion when the carbonized kernel, the combustible gases and vapors, have gradually freed themselves from their surrounding incombustible mantles. The result will be much smoke due to the minute kernels of cracked oil residues. To counteract this nuisance an excess of air has to be admitted with the oil spray which means of course serious inefficiency. Another remedy against incomplete combustion is to fit a perforated brick screen in the midst of the flame. It will create a turmoil and thus bring the unconsumed gases and vapors into contact with the remaining oxygen during, and not after the first combustion, and as this turmoil takes place in the proximity of whitehot brickwork combustion is likely to be complete, provided the oil globules were not too large at the start. Such screens have to be made of the best firebrick otherwise they will melt.

The object of atomisers is therefore to produce oil globules of the very smallest dimensions. Now whatever the type of burner, the oil necessarily is in contact with a hard surface, and gliding along it acquires a rolling motion before it is liberated. This rolling motion is probably the chief atomising factor, for the bursting pressure due to centrifugal force increases with the square tension of the oil, which is very powerful in small globules. The surface tension diminishes with increasing temperature and disappears at the boiling point, therefore warmed oils atomise more easily than cold ones. A good burner should produce a high rotary motion in the oil globules. Many oil burners are merely ejectors and impart very little rotary movement to the oil. The worst type would be a spray of oil impinging on wire netting, for here two particles of oil, after rapidly sliding round a wire and acquiring some rotary motion, meet before being blown off and naturally destroy their opposing rotary movements. Obstructions of any sort in front of a burner are bad. It is also probable that large creeping surfaces for the oil are bad because the long continued friction must reduce the velocity. Rounded edges of nozzles are likely to produce very large drops. Possibly knife edges might improve matters. Apparently the burners which give the best results are the mechanical atomisers in which pressure is applied to the oil which emerges from minute orifices at a very high velocity. In steam and air atomisers as the names imply, the oil is not under pressure, but steam or compressed air impart their velocity to it. Much depends on the design. In the best atomizers thin films of oil acquire a rotary velocity which may be half as high of that of the steam or air, in others the steam or air merely propels the oil without breaking it up. In many atomisers the contact of the oil with the steam or air is at the point of greatest pressure. This seems to be a wrong principle; the steam ought to be allowed to acquire a maximum velocity as in the de Laval nozzles, before it strikes the oil film. Another principle which is more applicable to light than to heavy oils is to allow time for the oil to become thoroughly mixed with the steam (preferably superheated); the oil would by this process be vaporised, not atomised.

EXHIBITION NOTES

The Dominion Steel Products Co., Brantford

have an interesting exhibit. They have a 75 K.W. 375 r.p.m. high compression oil engine in actual operation, and this is said to be the first Diesel engine completely designed and built in Canada. Mr. W. W. Brown, the designer, gave Canadian Machinery a complete description of the engine and while one cannot go into a full talk on the matter in this small space, we can say that the exhibit is well worth a visit. Each cylinder is identical in assembly, and interchangeability is an accomplished fact. The writer saw the arrangements made and if desired one can disassemble any unit without disturbing its neighbor. Even the governor and other smaller parts are arranged on the same principle. The engine is very compact and is completely self-contained. They are said to be fully efficient under both steady and variable loads, this being of considerable importance to any heavy duty engine. The electric generator is, as stated before, part of the complete outfit, and the crane can pick up the complete self-contained unit and place it into position wherever desired. Full details are given in the literature, which is given to those interested.

In addition to the engine, the concern are showing a complete line of cast iron and steel chucks of the design which has already been explained in our columns. These chucks are very neat and their strength is already well known. A varied line of Darling valves is also shown, this company being exclusive Canadian agents for this line. The valves vary in size from 4 in. to 24 in., and hydrants of the Darling type are also shown. In fact a section of one hydrant is supplied. The exhibit is rounded out by the showing of a motor driven two stage auxiliary air compressor. All these various items have to be seen to be appreciated, and either Mr. Brown or the other gentleman in charge will be glad to explain matters in more detail.

* * *

The Canadian Ice Machine Co.

have an excellent exhibit of refrigerating machinery, supplies, and materials. They show a double pipe ammonia condenser; a centrifugal motor driven brine pump; a York double cylinder ice machine; an oil trap, bent coils; a sheet of pure compressed cork, and other supplies in this line. Mr. Haine and P. G. Hender will be at this booth.

* * *

Jones & Moore Electric Co., Ltd., Toronto

are showing a varied line of motors ranging from 1-6 h.p. to 25 h.p. A shoe repair shop outfit in operation is also shown.

* * *

The Lancashire Dynamo and Motor Co., Toronto

are showing a complete line of motors from 1 to 25 h.p. A slow speed motor for commercial sewing machines is shown, and all motors are equipped with ball bearings. A feature of these motors is that they only require greasing twice a year. Motor starters are shown, also a disassembled motor which gives visitors a chance to see the interior parts. Various photographs of installations are included in this exhibit. Mr. Powell, Mr. Steele and Mr. Adams are in attendance.

* * *

Messrs Peacock Bros., Ltd.

have a very varied line this year including Weir boiler feed pumps, Foxboro instruments, Aldrich Vertical triplex pump, Hopkinson valves, Richardson automatic scales, a line of instruments made by the Precision instrument Co., and an interesting display of steam traps, radiator traps, and temperature regulators made by the Darco Co., Inc. They also show the Merco Nordstrom non-sticking plug valve which is something new to this section of the country, a simplex valve reseating machine, a line of safety lamps, a miner's air pick, and other varied lines. This is a very complete exhibit, and Mr. Kudera will be pleased to answer any question put to him.

The Canadian Link Belt Co., Toronto

This company is showing a rather interesting installation, which they call "A Silent Chain paradox." A disk with nine slots revolves in front of a chain drive arrangement, and to the casual spectator certain of the chains do not appear to be moving although they are actually travelling at the rate of over 1000 ft. per min. The secret is that the sprockets used to drive these chains are all certain multiples of nine.

In addition to this drive, racks are shown which contain different kinds of malleable iron and steel chains, buckets, etc. There is also a rack containing their silent and roller chains, also photographs depicting the chains being made at their Toronto plant, also others showing actual applications of such chains. J. S. Stewart, E. C. Burton, R. C. Turner, and F. C. Conant are in attendance.

* * *

E. Pullman Wipers and Waste Co., Toronto

are showing a full line of wiper cloths, knenser kloths, and mop cloths. The latter are featured because they come to the customer in large pieces allowing them to be cut up as desired. They are also very soft and absorbent, two essential features in cloths of this nature. Competent officials are in charge ready to explain the uses of the various kinds of cloths.

* * *

The Dunlop Rubber Co., Toronto

show an interesting exhibit of rubber belting, fire hose, etc. An installation of a Gibraltar conveyor under power is shown, this consisting of a large rubber belt to which cast iron buckets are fastened. Fire hose, garden and industrial hose are also part of the exhibit.

* * *

The Black Donald Graphite Co., Calabogie, Ont.

are showing a complete assortment of their line of graphite products.

* * *

The W. R. Sexton Boiler Setting Co., Toronto

are showing their line of Elkco fire brick, this including special as well as standard shapes. They also are exhibiting their nonpareil dumping grate bars, together with a few boiler settings.

* * *

The Geo. W. Cole Co., Toronto

are showing a very complete exhibit of their various lines, these including a miniature installation, boiler feeders, condensor traps, return traps, receivers, swing check valves, pressure reducing valve, etc. They also show a Kitt's pot trap, and a Kitt's pressure reducing valve. The exhibit is well arranged and G. E. Cole and J. E. Farrell will be in attendance.

HOW TO GET RID OF RUST ON IRON OR STEEL BEFORE ELECTRO-PLATING

By RALPH H. BUTZ

In the electroplating of iron and steel it is always necessary to clean the surface from grease, oil, rust and other foreign matter previous to plating, otherwise, of course, the deposit will not adhere to it. The cleaning of the surface leaves a chemically clean surface and one which is in the ideal condition for rusting. It is not uncommon to find a plater who will carefully clean rust from an iron or steel surface for the purpose of plating it, and then, before the actual plating operation takes place, unknowingly allow it to rust again.

After pickling or cleaning off the grease or other foreign matter, the plating operation will be satisfactory if the article is carried, after being rinsed, directly to the plating tank, as it then will not have an opportunity to rust; but if it is allowed to remain some time, as it is usually required to do, before plating, then trouble usually commences.

Iron or steel which has been cleaned and is ready for plating should never be allowed to dry, if possible. If it is allowed to dry, then it will invariably rust. As it is always impossible, however, to plate the articles immediately after cleaning, and they must remain for some time previous to this operation, then some process is necessary to prevent rusting during such interval.

Clean surfaces of iron or steel may be prevented from rusting by immersion in an alkaline solution of some nature. It does not matter just what this alkaline solution is, but it must be strongly alkaline. Among the substances that can be employed are: Sodium carbonate, sodium bicarbonate, potassium carbonate, caustic potash, caustic soda or lime. These substances, of course, should be dissolved in water. The one which is most satisfactory is sodium carbonate (carbonate of soda or salsoda). This is cheap and readily dissolves in water. Lime water can be used but is not as good as sodium carbonate for the reason that it is apt to leave a film of carbonate of lime on the work, and this must afterwards be removed with weak acid. The sodium carbonate is the best substance for the purpose.

Editor's note:—At present there are several preparations on the market that claim not only to cleanse the parts, but protect them from rust. Recently we were privileged to watch a demonstration of such a compound, and the parts dipped were not only allowed to dry, but were left for some considerable time without any sign of rust. Rust can be likened to one rotten apple in a barrel of good apples. Once let it get a start and it will go through the whole barrel

The D. K. McLaren Co.

have an interesting exhibit showing single and double belting and supplies for the textile trade in general. The belts include waterproof leather, balata, etc., and an interesting installation of two belts running through water is shown. Split pulleys, belt dressing, belt fasteners and other accessories are included. This booth is featuring a very neat case which contains a collection of card clothing belts for woollen and worsted carding. These show the different size and style used in the various operations and over 30 samples are shown. This in itself is worth inspection and W. S. Hamilton, who is in charge of the exhibit invites anyone interested.

* * *

The Clipper Belt Lacing Co.

have a neat exhibit showing the many applications of their well known product. Mr. Logan is in charge of this booth and claims he is ready to meet all comers.

View at Canadian National Exhibition, Looking Towards Horticultural and Transportation Buildings.

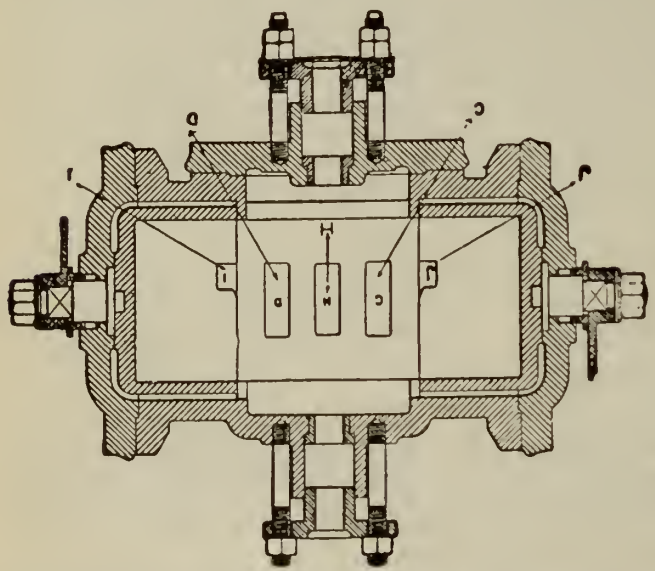
Overhauling and Adjusting in the Engine Room

Following Up Previous Articles, We Now Describe the Weir Feed Pump, Which Has a Steam Valve Differing From All Those Previously Discussed, Though the General Principle Remains

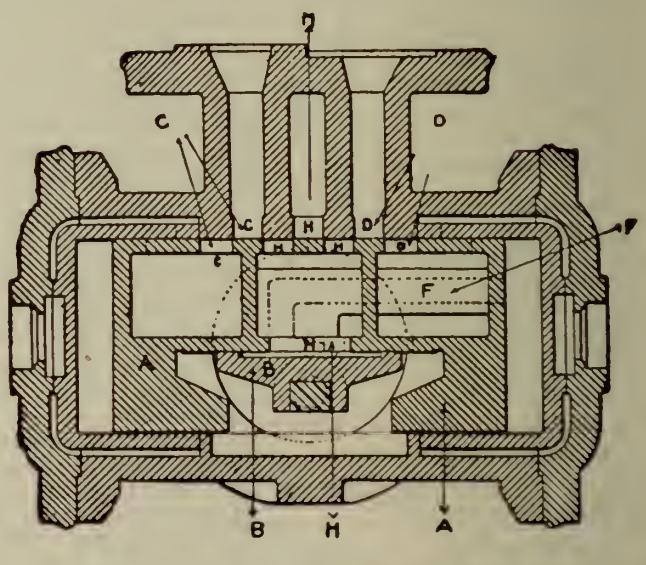
By "FITTER"

Following on the subject of simplex pumps, we will in this article describe a pump that is coming into use in Canada as a boiler feed pump for stationary plants. This pump, is widely known in marine work, there being probably more of them in use at sea than any other type of pump made. The steam valve of this pump is often thought by those unacquainted with it to be a terribly complicated affair, but it is just as susceptible to analysis as any other form of simplex valve. The pump alluded to is the Weir feed pump made in this country by Peacock Bros. Montreal, under license from the originators, Messrs. G. & J. Weir, Glasgow.

Like all other simplex pumps, the steam valve arrangement consists of a main valve and an auxiliary valve, the main valve being moved by steam delivered to it by the auxiliary valve, while the auxiliary valve itself is moved by the pump rod. In this pump however, the auxiliary valve also with its outer edge, cuts off the steam entering the ports to the cylinder.



Showing steam chest ports and valve caps.



Sectional plan showing general arrangement.

The main valve and the auxiliary valve are both slide valves, but the main valve has a half round face in communication with the cylinder while on the back of the valve the face is flat to form a seat for the auxiliary valve to work upon. The main valve has a horizontal motion, while the auxiliary valve works in a direction at right angles to the main valve, that is up and down across the face of the main valve.

Description of Valve

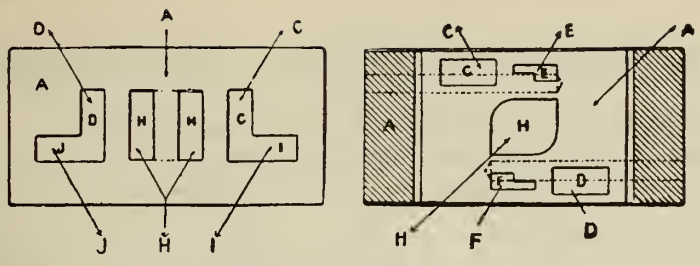
The valve will be described in detail, and in order to make everything clear we will take it piece by piece, afterwards describing the whole operation. The first illustration shows a sectional view of the cylinder face ports, with the caps in which the main valve works. As we have not mentioned these caps before we will do so now. They are actually small cylinders, into which the ends of the main valves fit like a piston. They are free to turn round in the steam chest, but cannot move longitudinally as can be seen from the illustration. They are held at one end by the steam chest end cover, and at the other by a shoulder formed on the steam chest. On the illustration a small spindle can be seen passing through the cover, and fitting into a slot in the valve cap or cylinder. This spindle is supplied with square or hexagon end, on which a spanner can be fitted to turn the cap round. This is necessary when using the by passes which will be explained later.

Looking at the illustration again, we see that there are three ports in the cylinder face, and these are as usual two steam and one exhaust port. The steam ports are C and D while the exhaust port is H. The two ports I and J are out on the caps, and are used as by-passes just referred to. We can now pass on to the main valve, and describe the ports on it.

The illustration showing the sectional plan of main valve, auxiliary valve, and caps shows the general arrangement of the steam chest. The main valve is marked A, and it will be seen that it fits in the caps at each end just like a piston in a cylinder, while the flat face formed on the back for the auxiliary valve is plainly seen. The auxiliary valve is marked B. It will be seen that the main valve face has four ports on the face communicating with the cylinder, two exhaust and two steam, the ports being lettered to correspond with the steam chest face ports.. The port F shown dotted is the port leading from the back of the main valve to the end, which admits steam to move the main valve. The other port E communicating with the other end is not visible, as it is above the section taken. The valve is shown in mid-position. The sectional view shows the semi circular form of the main valve to the spindle, while the ports E and F which communicate with the ends are plainly shown. If we now turn to the illustrations showing the front and back face of the main valve and the arrangement of the auxiliary valve, and observe the port arrangements, we will be in a good position to understand the operation of the valve as a whole.

The Main Valve Faces

The front face of the main valve, that is the face that works on the steam chest face has four ports cut in it. The two outside ones have a projection turned towards the edge of the valve, and these are the by-passes, that communicate with the opening in the cylinder or caps when they are turned round in the steam. Their function is to provide a supply of steam to the main cylinder after the normal point of cut off has occurred, when such supply is necessary to make the pump complete its stroke. The up and down portion of



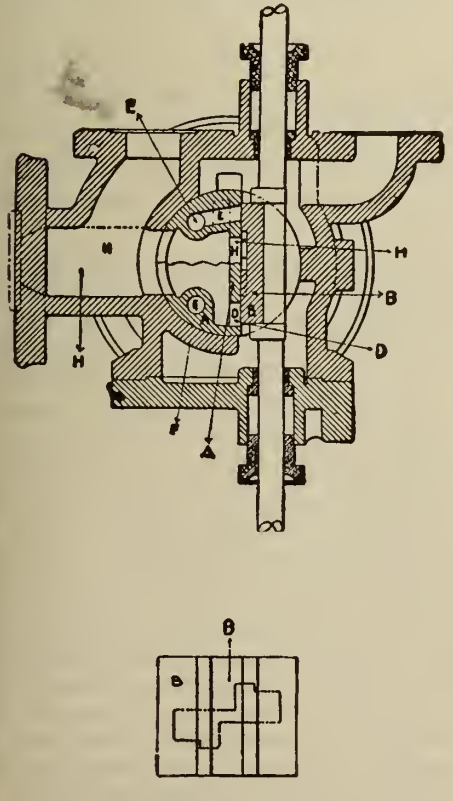
Front face of main valve and back face of same.

the ports C and D constitute the main steam ports, and the two inside ports H H are the exhaust passages.

Now on the back of the main valve, that is the flat portion on which works the auxiliary valve, we have five parts. Two af these, above and below central port H which is the exhaust port, are lettered respectively E and F, and their function is to supply steam to the ends of the main valve, and also exhaust steam from the ends of the main valve to allow it to move from the end of its chamber, and thus open the ports to the cylinder alternately to steam and exhaust. The other two ports C and D communicate through the body of the valve to the ports C and D on the inside face of the main valve.

The face of the auxiliary valve B has a capacity as shown by the dotted lines, which cavity gives communication with the exhaust ports from E and F alternately to allow the steam at the ends of the cap to be exhausted. The outside edges of the auxiliary valve also cut off steam from C and D as the valve moves up and down with the movement of the pump.

In the view showing the general arrangement of the valve the main valve is shown in mid-position, and steam



Sectional elevation above, auxiliary valve below.

and exhaust valves are closed. This condition never occurs in practice, as the valve must be either at one end of its stroke or the other. Let us suppose that the valve is at the right hand end of its travel and the port C is open to steam. This port leads to the bottom of the cylinder, and the piston is at the bottom of the stroke, about to commence its upward movement. The piston will move up, and when it reaches approximately its half stroke, the lever which is attached to the pump rod, will come up against the nuts on the valve spindle rod, and start to move the auxiliary upwards. When the piston has reached three quarter stroke the outside edge of the auxiliary valve will have cut off steam from the port C while as the auxiliary continues its upward movement, the port E will be laced in communication with the exhaust, and F with steam, when the main valve will move over, and give steam to the other end of the cylinder. It will be noted that the steam has been cut off from the main valve when the piston is at three quarter stroke, so that the stroke must be completed by the expansion of the steam under the piston. If the cylinder is cold, or the initial pressure weak, the piston will not complete its stroke, so that some help must be given it. The caps at the end are turned round in the chest until the by pass comes in line with the extension of the steam port on the steam valve face and thus live steam is supplied to complete the stroke. If these by-passes are proper working condition however, these by-passes must be closed, otherwise the pump will knock heavily at each end of the stroke. If these by-passes are properly looked after the pump will slow down at the end of its stroke come gradually to rest, and start off again without a sound.

The movement of the auxiliary valve is controlled by the position of the nuts on the valve spindle rod, and it is easy to see, that the closer together these are the sooner will the auxiliary valve start to act. The nuts are fitted with lock nuts, and they are easily adjusted when the pump is started, if they need any. The easiest way is to open the by passes, and giving the pump a little steam, adjust the nuts until the pump starts readily from each end. This shows that when the pump is at the end of the stroke, the auxiliary valve has been moved far enough to throw the main valve. The by-passes can then be throttled down and the full steam given to the pump, when any further slight adjustment should be made.

The ends of the spindles by which the caps are turned are secured by a lock nut, and the spanner which is supplied is also arranged with a slot in the end, which can be used for moving the valve spindle in starting the pump. This spanner should be used in just this way, and not as a means of hammering the pump under the mistaken notion that abuse will make it go.

The maintenance as far as the steam valve of a Weirs pump is concerned is of the slightest. It should be examined from time to time, and if necessary faced up like any other slide valve. However, if it is scraped up from time to time, it will be necessary to insert a liner between the back of the auxiliary valve and the valve spindle to keep their relative positions the same as when the pump is new. A little oil from time to time is necessary, and the makers usually furnish a special lubricator for this purpose. With ordinary care and intelligence, the operator will have nothing to find fault with in the operation of these pumps. We have heard complaints from engineers about their performance but have found invariably that the fault was not with the pump.

SOMETHING NEW IN WINDMILLS.

Many attempts have been made to solve the problem of efficiently utilizing the winds as a means of generating electricity. The difficulties arise from the extreme variations in the force of the wind and from the liability, even in windy regions, to periods of calm during which no power at all can be obtained. These conditions suggest that wind power should be used only as an auxiliary to some other source of energy, such as the burning of coal or oil. Now that fuel of all sorts has multiplied in price there is all the more reason for considering the possibility of turning the wind to account. Hitherto the usual plan has been to use a large slow-speed windmill to drive a dynamo at a high speed through gearing—a rather wasteful arrangement. During the war, however, there was in Great Britain a remarkable development in the design and construction of small high-speed dynamos on aeroplanes. These dynamos were direct-coupled to propellers or rather "impellers," driven by the wind created by the aeroplane in flight. A British firm has devised a scheme for fitting three or more of these wind-dynamos on the swivelling top of a vertical pole; with a vane to keep them in position against the wind. Each equipment gives 60 watts, and the arrangement forms a cheap and efficient auxiliary to the ordinary country-house lighting installation. The energy produced is, of course, stored in accumulators in the usual way. The operation of the plant is entirely automatic and it is so light and simple that it presents no obstacles in erection and maintenance.

The Internal Combustion Engine Discussed

The Two Cycle and Four Cycle Types with Their Advantages and Disadvantages are Mentioned by the Author, Who, However, Displays a Great Leaning Towards the Two Cycle Type

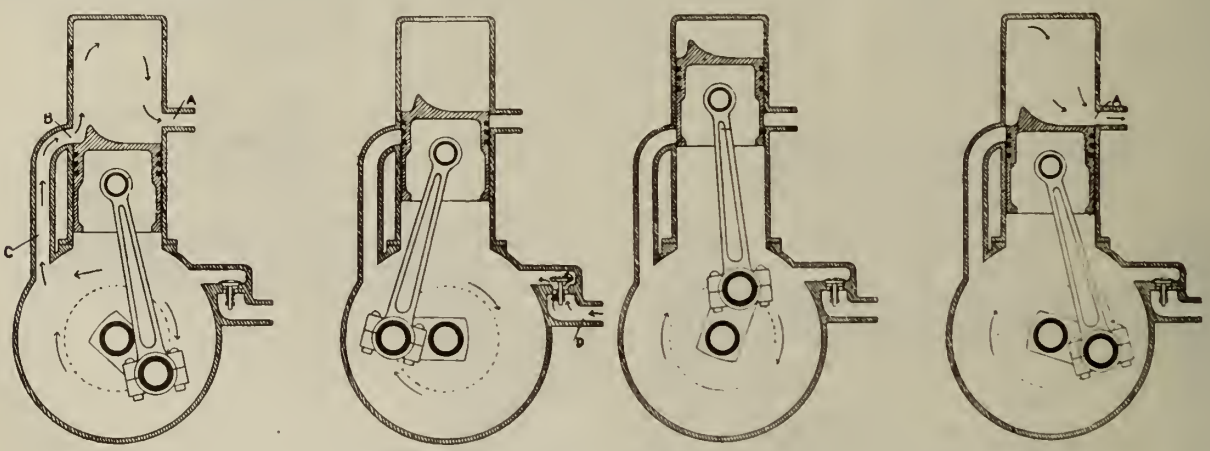
By A. W. BRADBURY

IN the reciprocating steam engine, power is derived by the admission of steam under considerable pressure into a cylinder behind a piston which is driven outward by expansion of the steam, and, through a connecting rod and a crank, this piston thrust rotates a shaft connected direct or by belt or gears to the object to be moved. In this process no chemical action takes place within the steam cylinder. All chemical action occurring in the generation of steam power is carried out in the fire under the boiler and the power stored in the boiler in the form of steam under pressure. The action of the steam engine itself, in using this stored power, is purely mechanical.

gas burned under a boiler to generate a given quantity of power in a steam engine will supply more than twice that quantity of power if consumed in an internal-combustion engine. Coal cannot well be employed as fuel for an internal-combustion engine unless first finely pulverised, hence the fuels for these engines are found in the liquid or gaseous form. If the fuel be a gas it is mixed with air and drawn into the engine by the suction of the piston, the mixture is compressed in the cylinder by the inward stroke of the piston and then ignited by an electric spark. Combustion of the mixture is practically instantaneous the resulting heat causes rapid and intense expansion of the contents of the cylinder and this expansion forces the piston outward on its power stroke.

one cylinder and by expansion in one cylinder against compression in another in multi-cylinder engines.

One expansion stroke and one compression stroke together constitute a cycle, in the two-stroke-cycle type of engine. In this form every outward stroke of the piston is a power stroke, every inward movement a compression stroke. here the burnt gas must escape and the fresh charge of air and fuel must enter the cylinder while the piston is at or near the outward limit of its traverse. This necessitates a rapid emptying and refilling of the cylinder. In engine parlance the process of ridding the cylinder of the products of combustion, i.e., steam, carbon dioxide, and other inert gases, and replacing them with fresh air or air and fuel mixture is termed scavenging the cylinder. In a two-stroke engine the cylinder is scavenged with every revolution of the flywheel.



FIGS. 1, 2, 3 and 4.

Diagrams 1 to 4 show a two stroke cycle engine in sections, in which Fig. 1 indicates the position of the ports when scavenging is taking place with exhaust gas escaping on the right, while a fresh charge is entering the cylinder on the left, through the by-pass from the crank case.
Fig. 2 shows inlet and exhaust ports closed by the piston on its upward stroke, with inlet valve in crank case open to admit a mixture of gas and air or of air only into the crank case.
Fig. 3 shows the piston moving downward under pressure of the expansion stroke and at the same time compressing the ensuing cylinder charge in the crank case.
Fig. 4 shows the exhaust gas beginning to escape before the piston has gone down far enough to open the inlet port on the left. The opening of the latter takes us back to Fig. 1.

In the internal-combustion engine both mechanical and chemical action take place wholly within the cylinder. Creation of pressure, heat, and expansion, in this order, all take place within the cylinder behind the piston and drive it outward or downward just as steam drives a piston.

In both cases the fuel consists of carbon and hydrogen, principally the former, mixed with the oxygen of the air in such proportion as to support combustion of the fuel elements. In the generation of steam power, coal, coke, and wood are convenient fuels and are the fuels generally employed, but liquid or gaseous fuels may be used, and are used. But this process is wasteful because of the quantity of oil, alcohol, or of operation" of an internal-combustion

At or near the end of the outward stroke of the piston the nearly spent gases are allowed to escape from the cylinder, through an exhaust valve or a row of ports, and a new mixture of air and fuel, or air only, is taken into the cylinder to be compressed ready for the next power stroke. The "Scheme engine is one of "alternate expansion and contraction"—expansion being caused by heating and contraction by cooling the contents of the cylinder, such cooling taking place very rapidly upon release of pressure on the gases by the opening of the exhaust outlet. The compression of the charge also constitutes a form of forced contraction, the force for which is supplied by the momentum of the flywheel in engines of

In this type of engine, scavenging is attained usually by two rows of ports in the cylinder barrel, placed opposite each other, the ports on the exhaust side being higher, or deeper than those on the inlet side. During the greater part of the stroke these ports are covered, and, therefore, closed, by the piston. As it moves outward on the power stroke the piston first uncovers the upper or inner portion of the exhaust ports and the burnt gases above the piston, still under pressure, begin to rush out. With the sudden release from pressure the exhaust gas contracts enormously. While it is rushing out, with the piston moving all the time and in-

*By A. W. Bradbury and read at a meeting of the Institute of Marine Engineers.

creasing the area of opening of the exhaust, the piston begins to uncover and continues to enlarge the inlet openings, whereupon the fresh charge of air, or air and fuel flows in through these. The escape of the burnt gas is continued through the momentum set up in the mass before the uncovering of the inlet ports, and this momentum would cause a partial vacuum in the cylinder if the inlet ports were kept closed. The entrance of the fresh charge is induced partly by the fall of pressure within the cylinder and partly because this charge itself is under pressure, for so it has been taken into the crank case during the inward movement of the piston and there compressed to a few pounds above atmosphere by the outward movement, the piston thus acting as a pump attached to the crank case. A by-pass connects the crank case with the inlet ports, through which the fresh charge flows to the latter. If nothing were done to prevent it, the incoming fresh charge probably would flow straight across the top of the piston and out through the exhaust ports. To obviate this a baffle ridge or plate is formed on the top of the piston, so shaped that it directs the inflowing charge toward the top of the cylinder.

Thus we find in the cylinder at the same instant two currents flowing in opposite directions, one composed of incombustible gas flowing downward and outward, the other of air or combustible mixture flowing inward and upward.

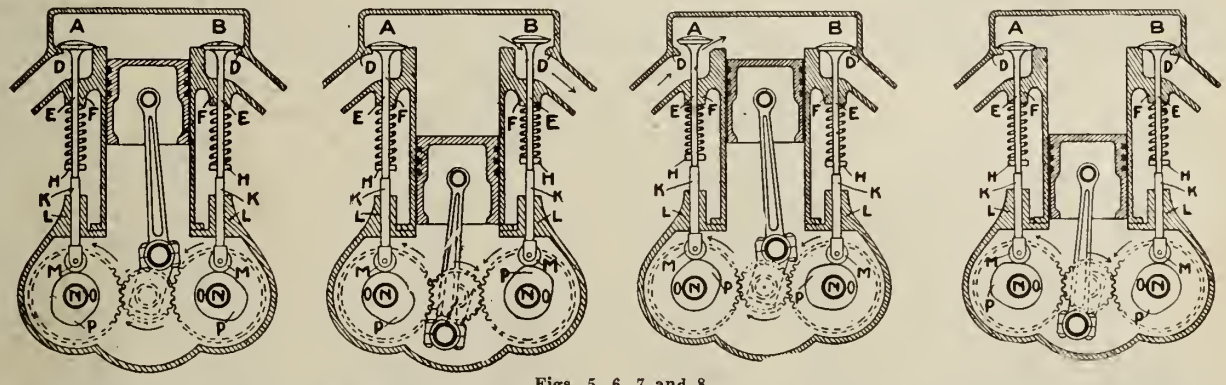
Various schemes have been put forward for improving the scavenging of two-stroke cycle-engines, in which the two rows of ports have been retained in the same end of the cylinder. Only one of these schemes appears to have proved of sufficient value to justify its retention in view of the increased cost of an engine so fitted. This consists of an auxiliary row of inlet ports, situated above the regular ports, through which additional air can be forced into the cylinder after the exhaust ports have been closed. This plan does increase the volumetric efficiency of the engine. But how can it improve scavenging per se?

The period of time during which scavenging must take place in a two-stroke engine is very short. The general rule is to make the area of the exhaust ports such that they allow for a gas movement of forty-five feet per second, based on piston volume and speed of rotation, and the inlet area large enough to permit the air to pass at eighty feet per second. If we follow these rules in an engine running at three hundred revolutions per minute, or five revolutions per second, and if the exhaust ports be open during one hundred and twenty degrees of the crank path, the gas must escape in one-third of one-fifth of a second, that is, one-fifteenth of a second, or fifteen times forty-five feet per second which equals 675 feet per second. The same ratio of port area to piston volume and speed should be maintained in other sizes running at other speeds, and such areas are ample.

The latest attempt to solve the scavenging problem in the two-stroke engine consists in a uniflow arrangement in a single-acting cylinder, in which the top of the piston is perfectly flat and the exhaust ports extend clear around the cylinder barrel, maintaining the pressure on the piston throughout nine-tenths of its stroke, and the fresh charge is admitted at the other end of the barrel. Theoretically this should increase the power and should be more economical of fuel than is, say a submarine engine in which the exhaust ports are uncovered whn the piston is only three-quarters of the way out on its stroke.

In the four-stroke-cycle engine we have exhaust gases escaping, and a fresh charge entering the same end of the cylinder but not at the same time. Instead of completing the cycle in two strokes, we have here two inward and two outward movements of the piston in which to complete it. This system enables the cylinder to be properly scavanged without any intermingling of opposing currents. Here the piston plays the part of a pump within the cylinder itself, and the crank case has nothing to do with the cycle. Beginning with a power impulse, the piston moves outward. At or near the end of the outward stroke a valve opens in the top of the cylinder and the returning piston pushes the burnt gas out through this valve. About the time the piston returns to the starting point this exhaust valve closes, and an inlet valve opens, which is in communication with air, or air and fuel. The piston then moves on its second outward stroke and draws air and fuel through the inlet valve into the cylinder. At the end of this stroke the inlet valve closes. Both valves being now closed, with the fresh charge imprisoned in the cylinder, the second inward stroke of the piston compresses the charge, which ignites and starts the piston outward on a new cycle. Scavenging is not so hurried here as it is in the two-stroke engine. One whole inward movement of the piston is given to forcing exhaust gases out of the cylinder. One whole outward movement to inducting a fresh charge, thus the four-stroke engine spends half of its time in compressing, firing and expanding the power charge, and the other half in pumping out burnt gas and pumping in air and fuel. It gives us one power impulse to every four strokes of the piston. The other type, one power impulse to every two strokes of the piston. If the two types run at the same number of revolutions per minute, the two-sroke engines fires twice as many charges of fuel in the same period of time as does the four-stroke. If the pressure on the piston was carried as far out in a two-stroke engine and if scavenging were as thorough, we would expect this type to develop twice the power of a four-stroke having the same cylinder capacity and the same speed of rotatioon. But it doesn't do it.

Thus far we have dealt only with two-stroke engines in which the scavenging is accomplished through ports only, and with four-stroke engines in which scavenging takes place through mechanically-operated valves. We now come to a modified form which is a two-stroke engine, so far as the cycle is concerned, but which employs mechanically-operated valves in the scavenging. In this form the usual exhaust ports are found, and they function in



Figs. 5, 6, 7 and 8.

Fig. 5 shows the piston moving outward on its expansion or power stroke with both valves closed. In Fig. 6 the piston has started upward with the exhaust valve open to permit the escape of burnt gas, pushed out by the piston. Fig. 7 shows the piston moving downward on the suction stroke with the inlet valve open to admit a new charge to the cylinder. Fig. 8 shows the valves now closed and the compression stroke commenced.

the usual manner. In addition there is placed in the cylinder head a scavenging valve, mechanically operated and communicating with a supply of air under pressure. On the power stroke of the piston, shortly after the upper edge of the exhaust ports is uncovered, the air valve is opened and the compressed air blows the exhaust gases out. This valve then closes before the piston has fully covered the exhaust ports again This arrangement assures satisfactory scavenging, but at the cost of an air pump with its connections, in addition to the cost of the valve and its operating mechanism. Still, in large engines, where the added cost bears small relation to total outlay on the plant, this method of scavenging has been found to be commercially practical. When the same results in scavenging can be attained in all types of two-stroke engines, large and small, without the extra air pump and valve operating mechanism, we shall have made a step forward in two-stroke design which which will be of greater value than any other improvements made in this type in many years. For undoubtedly the weakest feature of the two-stroke heretofore has been in the scavenging of the cylinder.

Such an improvement can be made, and in fact has been made. An engine embodying it will shortly appear in the field. With the scavenging bugbear removed, the prejudice against crank case compression still remains,at least in the minds of those who have not had extensive practical experience with the actual working of two-stroke engines. The cry of the uneducated is that you cannot see what is happening to the big end when closed in out of sight. The answer is that nothing happens to it. Another answer is that the big end is not throwing oil all over the place when closed in. But the man with the big phrenological bump of prejudice says the main bearings throw oil which the compressed air in the crank case forces outward. The answer to this is that they don't, if very simple precautions be taken to prevent it. Another complaint is that the automatic air inlet valves in the crank case cause trouble. Wrong again; if they are properly made, and not all two-stroke engines have them. Some have a third port uncovered by the piston when near the top of its stroke to admit air to the crank caes. Either arrangement is satisfactory.

The three port crank case compression, two-stroke engine is valueless. It is the simplest engine extant. Simpler than the simplest steam engine. It originated in England as a petrol engine. The inventor of the tuo-stroke petrol engine issued licences to firms in foreign countries, one of which built and sold over sixty thousand two-stroke engine prior to 1912.

Two-stroke engines have been in operation in every country in the world for more than two decades, the total number long ago exceeding the million mark. While such large numbers of them have been finding their way into every corner of the earth, British builders have stuck to the four stroke type. They have not expended money or energy in the development of the two-stroke. Had they done so there would to-day be less prejudice against this type. Power for power the two-stroke is cheaper to build, lighter in weight, occupies less space, and requires fewer repairs than a four-stroke. The popularity of the semi-Diesel and the success of the larger Diesels operating on the two stroke cycle are gradually bringing the two-stroke engine into its own.

It requires no valves, no valve springs, no tappets, no cams, no cam shaft, no half-time gear, no cam shaft bearings, no valve cages. Deduct the expense of these from your four-stroke job and see the difference in first cost. Or add the cost of these to a two-stroke engine and see how much more it costs. Then in running you have no valves to grind, no tappets to adjust, no gears to set in time, no cam shaft bearings to oil, none of these things to go wrong. In the four-stroke you have just two items to set against these advantages in the two-stroke, viz., a slightly lower fuel consumption and slightly better flexibility. With improved scavenging the difference in fuel consumption will become practically nil and the difference in flexibility is not a vital point. If the two-stroke-cycle engine were not satisfactory to those who use them to earn a living we should not find twenty semi-Diesels of the two-stroke type to one of the four-stroke. And unless those who devote their lives to the design of engines were not satisfied that the two-stroke is perfectly practical from every standpoint we should not see one large two-stroke Diesel after another rapidly coming into competition with the already established four-stroke machines.

In gas, petrol, and paraffin engines, where the fuel is mixed with air before admission to the cylinder, throtling is accomplished simply by a reduction of the quantity of mixture taken in on the suction stroke, by a butterfly valve placed in the induction pipe. This valve controls the quantity of air admitted, and since the quantity of fuel entering the cylinder depends upon the air current; the richness of the mixture is not greatly affected by the action of the throttle valve. And because the charge is fired by an electric spark, ignition is certain.

But in an engine in which air alone is drawn into the cylinder to be compressed and the fuel forced into the air charge when compression is far advanced, the case becomes entirely different. In the Diesel engine where we depend solely upon the heat of compression to fire the charge, it is evident that to throttle the charge of air would be to reduce the compression, lose that heat and fail to fire.

In the semi-Diesel engine ignition is brought about by a "hot spot," which depends upon obtaining its heat partly from compression. True, it is the burning of the fuel which raises the temperature of the hot spot to redness, but because it is already warmed to a considerable degree by the heat of compression, the explosion heat carries it on up to a temperture at which it ignites the fuel. Take away the heat of compression and the hot spot sooner or later cools down to a point where it will not fire the charge, and this is what happens when we reduce compression by throttling the air inlet.

In this type of engine the compression of the air varies more than in any other type. In some semi-Diesels compression is as low as nine atmospheres, isothermal In others it is as high as eighteen atmospheres. In two or three engines it is still higher. The average semi-Diesel compression is perhaps in the neighbourhood of 150 lbs. per square inch isothermal or, say, 210 lbs. adiabatic, if we disregard the effect of the cooling water. Owing to the rapid compression, and the rapid repetition of compressions in running on full load, the cooling water probably does not affect the adiabatic temperature to any marked degree. If the air be uncooled, rapid compression of it to 150 lbs. per square inch raises it to a temperature of 589 degs. Fah., if taken into the compressor at a temperature of 60 degs. Fah. Such a temperature is high enough to vaporise any of the mineral oils used as fuel in an oil engine. Presumably such compression also raises the temperature of the hot spot to a corresponding degree. The design of the engine is such that the heat of combustion will then add to the hot spot the heat required to raise it to the point where it ignites the oil, and maintain it at that temperature, even when the engine is running light. It is obvious that if we throttle the air inlet in an engine of this type the heat of compression will be very much reduced. If we reduce compression to 100 lbs. per square inch we obtain an adiabatic temperature of 485 degs. Fah. In reducing the pressure 50lbs. we have reduced the temperature 104 degs. If the hot spot be reduced 100 degs. in temperature, irregular firing is sure to follow and soon after it will fail entirely.

In order to run on part load or no load it is better to go on compressing the full quantity of air at every revolution, and thus retain all the heat of compression, and to regulate the speed of the engine by reducing the amount of fuel fed. We pay no attention to mixtures, "rich" or "lean," in the semi-Diesel engine, nor in the true Diesel, for that matter. There is always in these engines a quantity of air in excess of that required for combustion, so that, in governing them, we are not obliged to reduce the air when fuel is reduced, nor to increase the quantity of air to meet an overload. Another point to be remembered is, that all power expended in compressing air in the cylinder is returned

in the rebound of the compressed, and, therefore, heated, mass. In a few makes of semi-Diesel engines an arrangement is fitted for throttling the air in the by-pass between the crank case and the cylinder. On the other hand an engine brought out recently has a valve which prevents air from entering the crank case until the piston is part way on its inward movement, and so has created a partial vacuum in the crank case. The valve then opens, permitting the air to enter with a rush, which continues until the air in the crank case exceeds atmospheric pressure, upon which the valve closes and the return of the piston compresses this air ready for scavenging the cylinder. The same effect could be produced in the ordinary three port engine, possibly, by increasing the area of the crank case inlet ports circumferentially. The effort to get air into the crank case above atmospheric pressure certainly seems more reasonable than to reduce the scavenging air by throttling it. Not less scavenging air, but more is what we want in the ordinary, two-stroke semi-Diesel engine, in which both the exhaust and inlets ports are in the same end of the cylinder barrel and are both open at the same time. In this type we do not lose any fuel in scavenging, as may occur in those engines where the air and fuel mixture is employed for scavenging. If we can get enough scavenging air through the semi-Diesel cylinder to sweep out all of the burnt gas, we shall then compress nothing but pure air. We can then burn more fuel than we do where a certain quantity of burnt gas remains mixed with the fresh air charge.

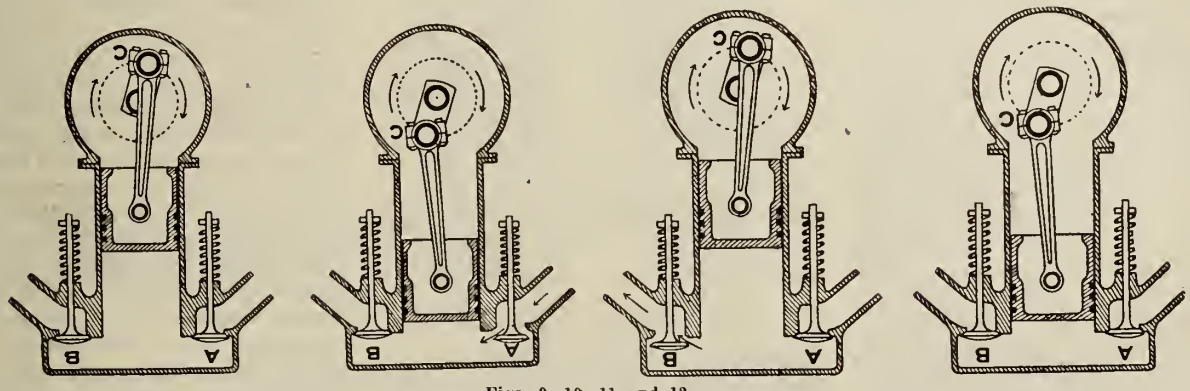
Fuel injection valves are employed in all makes of Diesel engines and in a large proportion of the semi-Diesel type. In the Diesel engine the injection valve is arranged to retain within the nozzle the fuel required for each charge until the proper instant for injection, then to lift and permit the fuel to be blown into the cylinder by an air blast under a pressure of 900 to 1,000 lbs. per square inch, through a series of staggered holes in thin steel plates fixed in the fuel nozzle. In this case the fuel pump exerts no pressure save that necessary to deliver the oil into the nozzle space surrounding the injection valve. The latter when closed prevents both air and oil from entering the cylinder. At the proper point in the cycle the valve is opened mechanically and the air blast effects the injection. In such case the fuel nozzle possesses a single, central opening and the valve is tapered to a needle point, to plug the opening when the valve is closed. In Diesel engines having a so-called solid injection the arrangement is different. Here no air blast is used. Instead of air a resilient fuel pipe is employed and the fuel forced into this by a ram pump to a very high pressure. This fuel supply pipe is made of thin, high tensile steel, is oval in section, and extends along the side of the cylinders, with a small branch pipe leading to each injection valve. The tips of the fuel nozzels are hemispherical in shape and each contains several very small holes, which diverge somewhat from the centre line, and communicate with a central hole. which is plugged by the fuel valve. The pumping of fuel into the oval pipe to a pressure of something like four thousand and in some cases even as high as 8,000 lbs. per square inch, causes this pipe to spring outward on the direction of its shorter diameter, that is, the high pressure tends to spring its flat sides outward and make the section more nearly round. Then when a fuel valve opens and thus relieves the pressure somewhat, the return of the pipe toward its original shape is the force which injects the oil into the cylinder.

In the semi-Diesel engine, lower fuel pressures are involved because the compression pressures in the cylinders are not so high as in the true Diesel. The greater number of semi-Diesels have fuel nozzles in which there is a single central spray hole. Just a plain round hole in the smaller sizes and a hole with rifles in it for the larger cylinders. In calculating the size of this hole the volume swept by the piston is the basis upon which to work, regardless of the speed of the engine. For example, a swept volume of 300 cubic inches would require a spray hole about fifteen thousandths of an inch in diameter. The shorter the hole, that is, the thinner the metal through which it is drilled, the better the atomization of the oil, for a long hole through thick metal tends to wire-draw the oil and feed it in a thin stream. In some engines having fuel nozzles of this type a simple check valve is placed as near to the point of the nozzle as possible, while in others no valve is put in the nozzle. In the latter a short, sharp stroke of the fuel pump is relied upon to break up the oil at the spray hole. Other engines have a needle valve, spring loaded, which is opened by the pressure of the fuel oil, and this is better, because less likely to permit any dribble of the oil at the finish of the injection.

Whatever the form of spray hole and whether valveless or not, the fuel nozzle should always be well water-cooled, and unless is contains a valve it should always be inclined upward at a considerable angle above the horizontal, to prevent air locks and to guard against dribbling of the fuel at the end of the injection. An air bubble at the fuel line anywhere between the pump and the nozzle is fatal to regular running of the engine. For this reason every fuel nozzle must be designed and mounted in such a way that air locks cannot by any possibility occur.

If injection nozzles and valves be properly designed and carefully made; if they be throughly water-cooled; if they be mounted properly, and if their connections are all they should be, they are not likely to give any trouble except from dirty fuel. This is the cause of most of the trouble arising in this particular fitting. It is essential, then, that fuel filters be ample in number and made of gauze fine enough to strain out all particles of dirt large enough to choke the spray hole or interfere with the seating properly of the injection valve. . If the mesh of the gauze be smaller than the spray holes, and if strainers be cleaned frequently, no dirt is liable to reach the spray holes. And yet, when an engine stops suddenly without apparent cause the first rule is, look for dirt.

There is a type of engine, known on the Continent of Europe as the Brons and on the Western Continent under half-a-dozen diferent names, in which no force is required to feed the fuel. Hence the function of the injection valve is



Figs. 9, 10, 11 and 12.

Fig 9 shows the piston moving downward on the power stroke, both valves closed. Fig. 10 shows piston moving upwards with the exhaust valve open to admit of the escape of burnt gas. Fig. 11 shows piston moving downward on the suction stroke with exhaust closed. Fig. 12 shows piston starting upward on compression stroke with valves closed. The charge is then fired and the cycle repeated.

solely to measure the charge. In this type of engine a small shell cup is placed in the combustion chamber, having a number of fine perforations in the sides. On the suction stroke of the engine the fuel is deposited in this cup, and on the return stroke of the piston it is vaporised and ignited by the heat of compression. This, of course, involves compression pressures practically as high as those found in the Diesel engine.

As to what actually takes place in the Brons cylinder, the theory is that the rising heat of compression first vaporises a small quantity of fuel in the cup then ignites it, and the tiny explosion following blows the balance of the fuel out through the fine holes in the cup into the cylinder where it burns. We may not be able to agree with this theory but the fact remains that the Brons engine works beautifully, is economical of fuel, burns any grade of fuel that the Diesel does and is much simpler in construction than the latter.

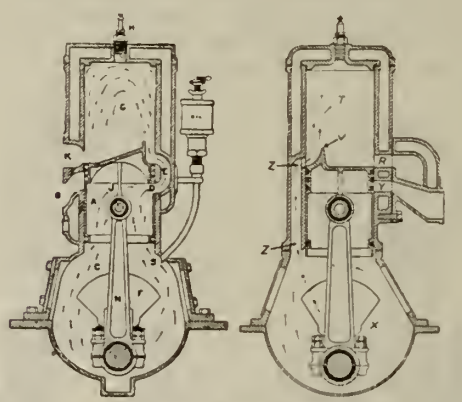
Fuel pumps of plunger pattern are, of course, necessary for supplying fuel under pressure to any type of oil engine. They are of two varieties, one of which has a suction valve on one side of the single plunger and a discharge valve on the other. Where balls are used as valves we sometimes find two on each side of the plunger—an indication that the designer does not have full faith in a single ball valve. And he should not have. The strongest argument in favour of a ball valve is that it is cheap. The other variety of fuel pump has two plungers, the secondary one of which is controlled by the governor in such a way as to keep the suction valve open for a shorter or a longer period, according to the quantity of fued required to correspond with the load on the engine. With the single plunger pump, governing is secured by varying the length of stroke of the plunger. Whatever the style of pump, it should be made of proper materials and the workmanship should be as nearly perfect as it is possible to attain, for the fuel pump is the heart of the engine. As to whether fuel pumps should be packed, those of wide experience hold opposing views on the question. A pump properly packed should work for years without leakage.

Fuel pumps can be made, and are made, which work under pressures of several hundred pounds per square inch for long periods without showing any sign of leakage and without any packing whatever.

Small oil engines, up to about fifteen horse power, are started by hand, by pulling the flying wheel against compression. These cannot be started by revolving them in the direction of running, whether they be two-stroke or four-stroke, because ignition cannot be retarded, as is don in an electric fired engine.In pulling against compression the charge fires before the piston reaches top centre and starts the engine back the other way.

Stationary engines having large flywheels with spokes require no other device for starting them. Using the spokes as handles, the flywheel is thrown against compression, that is to say, it is given as much momentum as possible and the operator lets go just before the engine fires. For if he holds on until the charge ignites he may receive a sprained wrist.

In marine engines having flywheels of disc pattern the best provision for starting by hand is the fitting of a disappearing handle in the rim of the wheel. By hooking three fingers over this handle and pulling against compression until the firing of the charge jerks the handle away from the fingers, the engine starts at the first pull and the operator runs no possible risk of injury, for the handle flies in flush with the wheel the instant it is freed from the hand. Such a handle is useful also for turning the engine over, in sizes too large to be started by hand. In still larger sizes, where more leverage is necessary to turn the engine, holes should be provided in the face of the wheel rim into which a bar may be inserted, but these holes should not extend entirely through the rim. If they do there is danger of shoving the bar too far through and failing to get it out quick enough if the engine fires. The bar is not to be used for starting the engine, but only for turning into position for starting, but sometimes when turning an engine over while hot, it will fire unexpectedly. The cranking bar should be made specially for the purpose, straight on one side and rounded longitudinally on the other, so that only the straight or flat side can bear against the side of the hole. It should have a projection or hook on the rounded side to bear against the face of the wheel. If the wheel should then move suddenly in the direction it is being turned the bar will be forced out of the hole. Relief valves in cylinders should always be opened before trying to turn a warm engine.



Figs. 13 and 14.

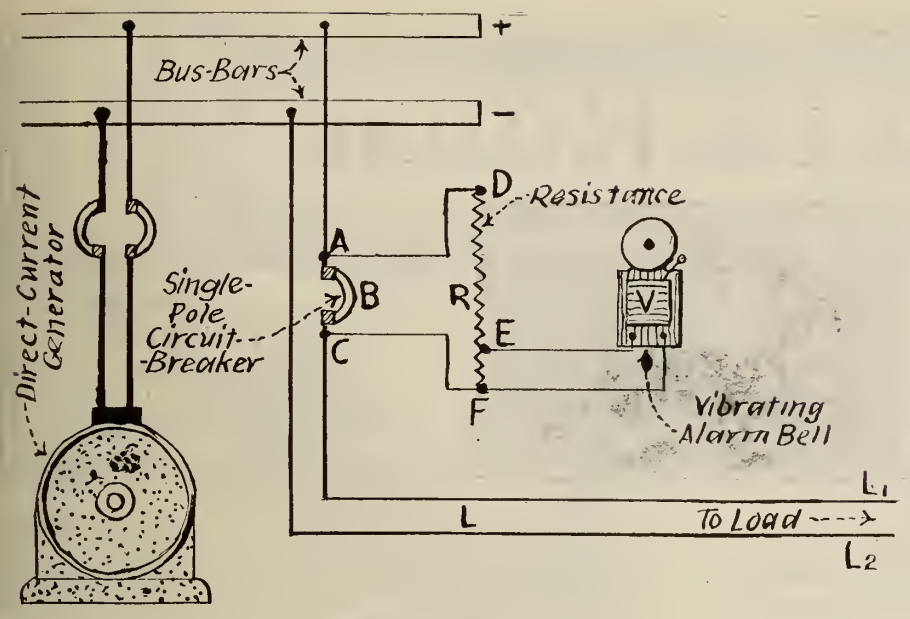
These diagrams illustrate a three port two stroke engine. Fig 13 shows the position of the ports during scavenging. Fig. 10 shows the piston about to start the stroke and thus opening the port to admit a charge to the crank case.

In engines too large to be started by hand, compressed gas or compressed air is generally employed: The gas is accumulated while the engine is running, through a special valve fitted in the cylinder and connected to the starting tank. The objections to this system are: 1st., that the connecting pipe gets hot; 2nd., the valve stems sometimes stick, owing to the heat and to the impossibility of lubricating them; 3rd., carbon deposits form on the valves of the connections. causing loss of compressed gas by leakage. For these reasons compressed air is preferable, as it has none of these drawbacks. Accumulation of the air is best obtained by means of a small air compressor attached to the engine. This need not be large enough to require water cooling. It runs while the engine is running and stores air enough for starting purposes. It should be fitted with a relief valve or, better, with a three-way cock, so that is can be relieved from compression air when the pressure in the tank is as high as required. Of course, neither gas nor air can be accumulated by an engine for starting the first time, nor for starting it in the event of the pressure tank having been emptied by a leak. This makes necessary an auxiliary arrangement of some kind and this generally consists of an air compressor worked by hand, for filling the air tank for the first start. But the compression of air by hand is an extremely slow and laborious process and it should be avoided if there is any possible way of obtaining other power for the purpose.

In an engine of two cylinders starting air should be supplied to both, and in a four-cylinder machine to two at least. In those engines manoeuvred by compressed air it is, of course, supplied to all cylinders, or should be. The air should be controlled by mechanically-operated valves which will admit the air only through that portion of the piston stroke which is most effective, say, from about top centre through an arc of crank path of about 90 degs. To go beyond this is unnecessary and also wasteful of air. The function of the compressed air or gas is simply to give sufficient momentum to the flywheel to carry it over until the engine fires, and the air should be shut off as soon as it fires.

NEW MATERIAL

A new plywood material used for aircraft construction has made its appearance on the English market. This material, according to reports, should not be confounded with ordinary plywood, for it is something infinitely superior. It is said to be a super-plywood, which is actually sewn together. The layers are first cemented together with waterproof material and then stitched through in parallel rows about 1¼ inches apart. This gives a rigidity and resilience unattainable by any other method. Weight for weight, it is the strongest material yet evolved. The sheets are made to any desired size or shape up to 8 feet wide by 60 feet long, and from ⅛ inch to ⅝ inch thick, thus eliminating waste in the conversion.



Circuit Diagram For Alarm Bell

A SIMPLE POWER ALARM

In a certain plant, electrical power was transmitted over a line L, which was of considerable length. Delay often ensued in closing the power-station circuit-breaker (B, Fig. 1) after an overload had occurred at the far end of the line. The delay was due to the fact that the duties of the station engineer were such that he could not remain permanently in the power house to watch the circuit breakers. Consequently an automatic alarm to notify the engineer of the opening of the breaker, was improvised as shown. The circuit-breaker, B. which protected the line, was of the single-pole type. A resistor, DF, of high resistance was arranged in parallel around the circuit-breaker from the points A and C. Then an ordinary vibrating bell was connected across a portion of this resistor, as shown in EF. When the circuit-breaker is closed, practically no current flows through DF or through the electric bell, V, because the path AC, through the circuit-breaker, offers much the least resistance. However, if the circuit-breaker is now thrown open, because of an overload on L, then current will flow through DF and through the bell, V, provided the line, L1 L2, is closed at the load end by a machine being connected across it, or by some other conductor. With the circuit-breaker, B, open, if the vibrating bell rings continuously, it indicates a short circuit at the end of line L. The bell will continue to sound until the circuit-breaker is closed. This audible signal attracts the attention of the operator, who then closes the circuit-breaker.

FINDING TROUBLE WITH A LAMP IN A FUSE BLOCK

(Copyright—All rights reserved)

An incandescent lamp can be used as a "test lamp" for testing out incandescent-lamp circuits. This test lamp is screwed, by the wiremen, into the Edison plug-type cut off or fuse block. When tests are being made in this way, the incandescent lamp, L, is inserted in the receptacle (on the ungrounded side of the circuit) of the cut-out, through which the circuit is fed. The lamp serves not only as an indicator, but also as a resistor which limits the current through the circuit. In case of a short circuit, as at S, the lamp will light. Or with a ground as at A, the lamp will light also. Trouble can thus be located by first putting the lamp in the service entrance cut-out plug and with all of the branch circuit connected. In the case of a ground or short circuit, lamp will light. Then both sides of each of the branch circuits are successively opened until the lamp goes out. This localizes the trouble to a single-branch circuit. Now the difficulty can be further localized by screwing the indicating lamp in the cut-out which serves the branch circuit, making test as above suggested.

In making trouble locations by this method, all of the incandescent lamps or their receiving devices on the circuits under test must be opened by the socket or individual switches, through which they are fed. The underlying principle of finding the trouble is that of elimination. With the test lamp in position in the cut-out, disconnect circuits or part of circuits until the circuit or the part of the circuit in which the trouble exists is identified.

SIMPLEX ROOF FLASHINGS

A booklet on "Simplex" galvanized iron, copper and all lead flashings has been issued by the Simplex Mfg. Co., Chicago, Ill., and can be obtained from their agents, W. H. Cunningham & Co., 269 West Richmond St., Toronto, Ont. Simplicity, durability and efficiency are claimed for this flashing, which consists of only three parts—the flange plate or base—the cone shaped sleeve—and a pure lead collar. It is stated that these flashings will fit any angle of roof from 50 degrees to flat, and there is no need to stock different angles to conform to various pitches. This means a saving and economy in stock. Simplex flashings are guaranteed to perform every service for which they are made.

Power Plant Exhibits

STROLLING through the machinery hall at the Toronto Exhibition, one is struck with the very small representation of firms dealing with power plant equipment, both steam and electrical. Of course, it is admittedly not a hall that lends itself to much of an exhibit, being overcrowded and inconvenient, but when one considers the exhibitions put up at conventions of engineers, the thought is born that at least there should be something worth while. An exhibition like the Canadian National Exhibition attracts practically every representative in the community, and not only operating engines, but owners of factories, superintendents, and what not, are passing round all the time. There is one exhibit, that is a Diesel engine in operation, that will be found of interest to the engineer, but why are there not exhibits of steam engines, steam turbines, various kinds of motors, and all the equipment of a power plant in one central spot, with a distinctive name so that those interested in these lines would know where to go?

The machinery hall while probably designed for those kind of things, in the beginning, is more and more taken up by the manufacturers of machine tools, and general industrial machinery, to the exclusion of all but a few firms specialising in power plant equipment. We believe that if the Exhibition authorities would find space, there would be enough firms to fill a hall devoted to steam and electrical power plant equipment, including prime movers and steam generators. Such an exhibit would attract a very large audience, and among them, a good percentage of prospective customers.

It Will Soon be Winter

THE advent of the Exhibition in Toronto serves the purpose among others of reminding us that the end of the summer is fast approaching, and the time of cooler air approaching. This to the ordinary citizen only conveys a feeling of relief from the discomforts forced upon him during the hot moist months. To the operating engineer, however, it has another meaning, that is that soon he may be called upon to supply heat to various parts of his plant. How he looks upon this prospect will depend largely on how he has availed himself of the warm season's hours to put his heating apparatus in thorough order. If he has gone over it from end to end, overhauling piping, both steam and return, radiator traps, reducing valves, vacuum pumps, etc. until he knows it is ready to function in every particular, he can face the coming cold weather with equanimity. If on the other hand, he is numbered among those who put off everything that shows immediate pressing need, he is in for some uncomfortable times. There are few things more annoying to an engineer, and few things that get him into quicker disrepute, than having factory employees and the superintendent complaining that the rooms are too cold to work in. This is bad enough, but there will be double the amount of howling if the main office, where the manager or proprietor has his august presence, is at a temperature below that necessary for comfort. There is no excuse that will avail when this occurs, and generally there is no excuse for it happening. There is generally enough steam to supply the heating requirements when the engine is running, and it sometimes happens that the engine exhaust is more than necessary, but some parts of the building are cold because of defective radiator traps, leaks in return pipes where there is a vacuum system, or risers filling with a water seal owing to a trap being out of order.

If the necessary repairs have not been made during the summer, there is very little chance of them being made before the spring once the heating system starts, and that means six months of discomfort for the factory employees, and recriminations for the engine room staff. Get your heating plant in order before the cold days come, and then you won't have double reason to dread the advent of a cold snap, but will be able to face the winter with confidence that all will go well.

Saving the Ice

SOME housewives have lately hit on an expedient for saving ice, which consists of wrapping the ice in a blanket or newspaper. There is no doubt that ice protected in this way will last longer than it otherwise would, but it will have a correspondingly smaller effect in keeping the food cool, or cooling it down when first put in the refrigerator. To carry the thing to an extreme point for the sake of illustration, if the ice were perfectly insulated it would last forever, but its cooling effect on the food would be nil. The only way that ice can perform its cooling functions is by absorbing the heat from the surrounding bodies and atmosphere in the refrigerator, and if the refrigerator itself were perfectly insulated, the ice would absorb the heat from the food and air in the frig. until they were at the temperature of the ice, and then everything would remain at that temperature until the doors were opened, admitting warm air. In the ordinary household refrigerator, the insulation is far from perfect, and a certain amount of heat is radiated through the walls of the frig from the outside air, which has to be absorbed by the ice, the result being that sufficient heat units are absorbed to effect the change from ice to water. Insulating the ice decreases its power of absorbing this heat, or rather the rapidity with which it will absorb it, and this means that it takes longer to cool the interior. You cannot absorb the heat from the frig. and keep your ice at the sam time, desirable as that result might be. The enterprising firms who are selling blankets for wrapping ice are trading on the ignorance of the average housewife where science is concerned.

It will soon be winter.

THE COKAL HAND STOKER

The Cokal Hand Stoker has been designed for those plants where the investment required for mechanical stokers is not justified. The Cokal hand stoker consists of an arrangement of bars adapted to be moved by levers and with several special features tending to added economy. The bars are supported by a trunnion practically in the centre so that the labor required to move them is very slight. Special arrangements are made to govern the loss of coal through the bars, and a varied ash discharge opening can be secured at will.

The range of size is large, from thirty inches square to one hundred square feet grate surface being possible. The following illustrations will give an idea of the operating principles of this stoker.

Figure 1 shows the stoker in the normal working position. The green coal is fired on the front of the stoker and the rear furnace temperature distils the volatile hydro-carbons, driving them over the incandescent coke which auxiliary, while large clinkers easily has been moved along to the rear, thus insuring complete combustion.

Figure 2 shows the stoker in the stoking position. In this position a half throw of the lever distributes the coke evenly over the stoker surface. All holes in the fire are filled, due to the action of the intermeshing bars. An uniform fuel bed is obtained, resulting in even air distribution through the fire.

Figure 3 shows the position when ash is being discharged, with the auxiliary discharge closed. A full throw of the lever operates the dump bar in the rear of the stoker, and the ash refuse is precipitated into the ash pit. For large clinkers the auxiliary is used, as shown in the illustration figure 4.

Figure 4 shows the combination ash and clinker discharge opening. With this combination three different sizes of opening are obtainable to suit the ash residue from the kind of coal used. With ash and small clinker the standard active dump bar is used with auxiliary close as shown in the previous illustration. Medium sized clinkers are discharged by operating the separate drop through by opening both dump bars and auxiliary as shown in figure 4.

THE JENNINGS HYTOR PUMP

The above pump which is manufactured by the Nash Engineering Co., South Norwalk Conn., and sold in Canada by the Arthur S. Litch Co., Toronto, is specially designed for handling returns from a low pressure heating system, and returning them to the boiler. The pump is also a vacuum pump, and it is claimed that owing to its peculiar design, it will maintain a vacuum on a heating system with a much less expenditure of power than the ordinary type of pump.

Description of Pump

The pump consists of two independent turbine units, an air pump and a water pump, combined in one casing, the impeller of each being mounted on the same shaft. One of these impellers continuously exhausts the air and vapor, and discharges it into the atmosphere, while the other impeller handles the condensate as it accumulates and discharges it to either hetwell or boiler. Thus the air and vapor does not have to be discharged against pressure, and the con-

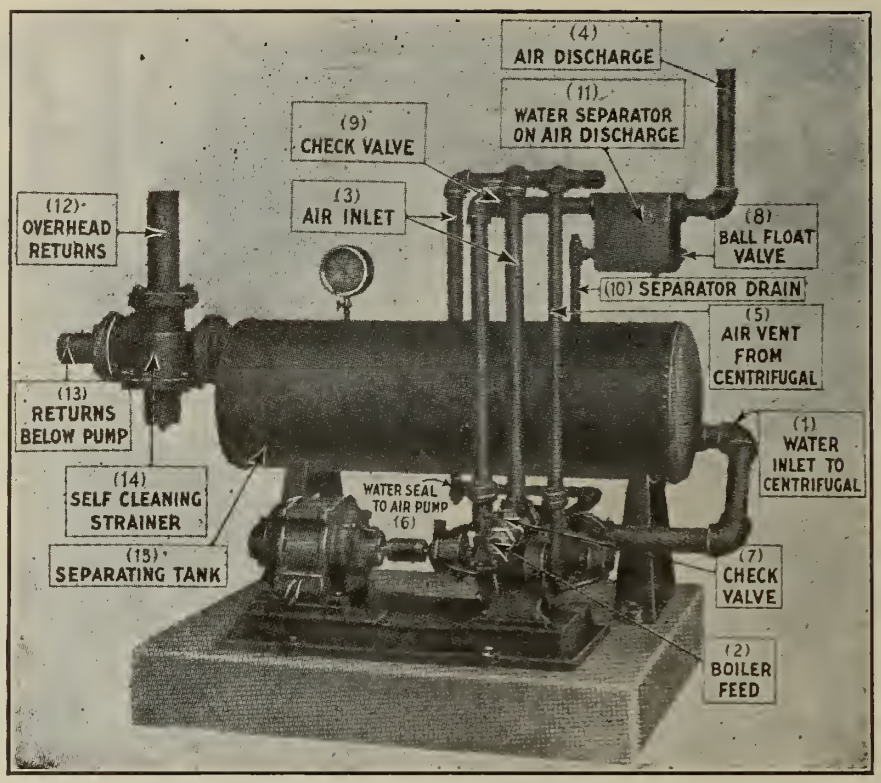

Fig. 3.—General arrangement of pump and receiver.

densate is returned free of air to the boiler.

The air unit consists of a rotor in hydraulic balance, revolving in a casing of elliptical form having large clearances. The water turned with the rotor, and owing to the action of centrifugal force will follow the shape of the casing, thus being forced away from the rotor by centrifugal force where the casing is large, and forced back onto the rotor by by the casing where it is small. When the latter action occurs, the air is compressed and forced out through the outlet ports. When the water is leaving the rotor in the enlarged portion of the casing, the air is drawn from the inlet ports by the vacuum created.

The water remains at the level of the outlet ports, the small amount drawn in with the air from the returns being delivered with the outgoing air, where it is separated and returned automatically to the heating system. The air unit being positive in its action, is capable of exhausting a large volume of air, and

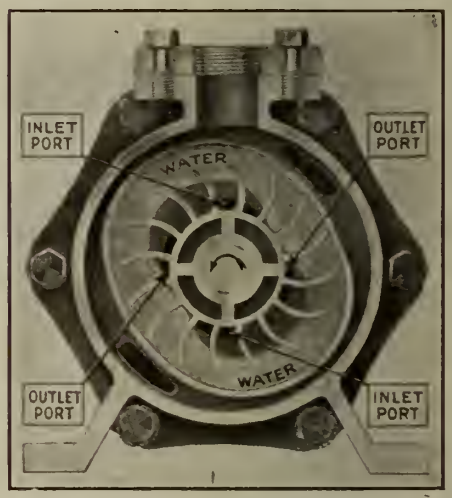
with freedom from any pulsation, as can be readily understood if the construction is examined.

The Water End

The water unit is a centrifugal pump specially designed to give high efficiency on either hot or cold water, and to unload when not handling water. The power required is closely proportional to the quantity of water pumped. The impeller is bronze, with renewable sealing rings.

The Operation

The operation of the pump is as follows. Referring to Fig. 3, the heating returns air and water, pass through the self cleaning strainer, (14) into the separating tank (15). The water falls to the bottom of the tank and passes into the centrifugal through the pipe 1, driving out the air through the pipe 5. As soon as the centrifugal is full of water it begins to pump and forces the condensation into the boiler through the pipe 2 emptying the tank. The centrifugal now stops pumping, being unable to handle air, and the check valve 7 prevents a back flow. The power required to drive the centrifugal is closely proportional to the quantity of water handled. It takes



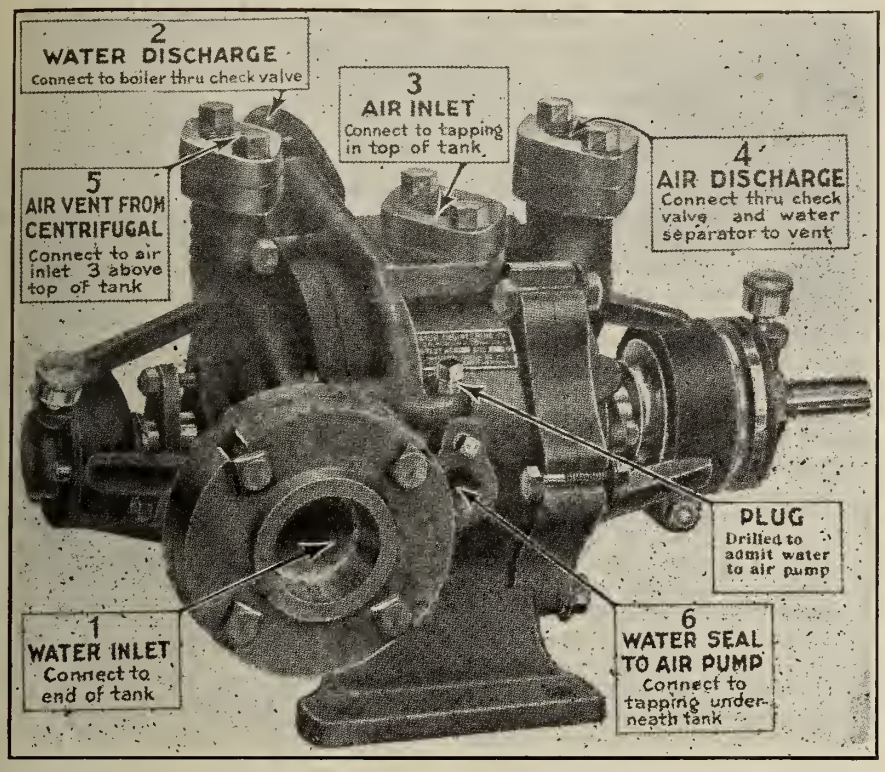
Construction of air pump.

almost no power when it is not pumping. The air is rapidly exhausted from the system by the air unit which is connected to the top of the tank by the pipe 3.

The small amount of water necessary to keep the air end primed is obtained from the bottom of the separating tank 15 by means of the pipe 6. The water is discharged with the air and is thrown to the bottom of the separator 11, and automatically returned to the tank 15, through the pipe 10, the ball float valve 8, preventing any air from re-entering the system.

Cut No. 4 shows the details of the bucket float mechanism.

The bucket is kept filled with water by the returns from their separator. When the bucket is submerged by water rising in the tank, the weighted arm outside the tank is heavier and falls, closing the switch and starting the pump. When the bucket is unsubmerged by the receding water, the weighted arm out-



Outside view of pump.

side the tank is overbalanced and rises, opening the switch.

The float is made of cast iron kept alwaysfull of water. It is therefore, not subject to derangement due to leakage—a common trouble with closed floats.

The float mechanism is exceptionally well made. The bronze shaft carrying the float and counterbalance arms is supported on each end by tin bushed bearings mounted in a cast iron bracket cast integral with a flange bolted to the tank.

By removing the bolts in this flange, the whole float mechanism may be removed from the tank as a unit. The lever arms are keyed to shaft. Forged forked connections are supplied to the connecting lever.

DESCRIPTION OF SUPERHEATER

Perhaps the best definition of a superheater is that it is an apparatus of an accessory nature, placed in a boiler to heat the steam, just previous to its discharge from the boiler, to a temperature higher than the definite temperature for the pressure, in order to avoid condensation difficulties, as this extra heat must be given up before any condensation occurs. Everyone familiar with steam knows that in its ordinary condition as generated in a boiler it has a definite temperature for every pressure. Ordinarily if heat is added to steam its pressure increases. If heat is taken away its pressure is reduced and a certain amount of condensation takes place. The steam, as generated in the ordinary boiler is known as saturated steam. Superheating the steam is accomplished by leading the steam off from the water, from which it is being generated, through the drier pipe to a superheater from the header, known as the saturated series header, usually placed in the smoke box, the steam is circulated through a series of coils placed in the flues of the boiler so that the gases of combustion, which are of a higher temperature than the steam, can impart still more heat to this steam. Sometimes it is necessary to alter slightly the flues or water tubes of a boiler. One might readily ask why the pressure does not increase. It does slightly but it is practically all equalized by the fact that there is no check valve between the superheater coils and the boiler proper. After the steam has circulated through these coils it is collected in the superheated series header from which it passes directly to the steam pipe connected with the engine, or turbine where the steam is used.

Saturated steam at 200lb. boiler pressure has a temperature of 388 degrees F. If this steam after passing through a set of superheater coils had a temperature of 488 degrees F. we would This heat must be given up before any say it had 100 degrees of superheat. condensation occurs. Superheater headers are made from cast iron or cast steel while the tubes now used in the high temperatures prevailing in most installations, are of steel. Some firms use a special form of seamless tubing with a forged return elbow all of which is in one integral piece. Superheater tubes are larger in diameter than the flues or the tubes. There are many interesting constructional details in these installations.

The capacity of a superheater is usually slightly in excess of the maximum boiler capacity.

Slow, But Not Sure.

"Do you drink coffee?" asked the doctor of an aged patient.

"Yes," was the reply.

"Coffee," continued the M.D., "is slow poison."

"Yes, very slow," replied the old man; "I have taken it daily for nearly eighty year."

SMOOTH-ON INSTRUCTION BOOK. No. 18

A pocket booklet, 4-inch by 6-inch and containing 144 pages of useful information and instruction on the uses of Smooth-On, has been issued by the Smooth-On Mfg. Co., Jersey City, N.J. Smooth-On is put up in 7 different forms for various purposes and the makers also manufacture an iron concrete paint and a Smooth-On coated corrugated iron gasket.

The book is profusely illustrated showing actual repairs done by Smooth-On in mending leaks and breaks in machinery, castings and a wide variety of articles.

Production Welding of Varied Steel Products

The Reactions—The Operation—Depth of Fuel Feed—Mechanical Producers—Capacity of Producers—Producer Fuels—Slagging Producers

THE essential features in the efficient and economic working of a producer can be enumerated as follows: (1) Even distribution of coal; (2) uniform and continuous production of good-quality gas; (3) a regulation of depth of fuel bed to obtain as complete as possible of CO to CO_2, and also the decomposition of the steam; (4) removal of ashes and clinker in as simple a manner as possible; (5) low cost of operating and installation with quick and efficient gasification.

The first important development that occurred was the method of increasing the speed of gasification. The rate of combustion obtained in the Siemens producer was very slow, which gave the idea to others that, seeing the regulation of the air was only by chimney draught, the application of a forced draught of air would accelerate this. The results expected were attained, but the heat was naturally intensified, which resulted in the formation of much clinker. This trouble was not felt in the original low-capacity Siemens type on account of the fact that the large area of grate bars allowed sufficient heat radiation to keep the temperature down below the melting point of the ash, which is the real factor to be dealt with in considering the clinkering qualities or tendencies of any fuel.

This question of clinker thus necessitated the devising of some method for the reduction of temperature in the producer, and the method adopted was the introduction of a jet of steam for blowing the air, thus giving the necessary vapour for temperature reduction. It was then discovered that the increased pressure in the producer due to the forced draught cause an extensive leakage of gas through the bottom, which resulted in the general adoption of the water seal which also allowed the easy removal of the ash without affecting the continuous operating of the producer.

To work in conjunction with the forced-draught producer various types of grates and tuyeres were designed, but the most effective has been found to be the conical mushroom-shaped tuyere of two or three domes, which gives a most uniform distribution of the blast to all parts of the producer.

Reactions

In tracing the reactions which occur in the producer it is best to start with the air alone. As it leaves the tuyeres the air passes through the ash bed, until it comes into contact with the fuel, at which point the fuel actually burns, completing combustion thereby, and forming CO_2, with the evolution of a large amount of heat. This heat is utilised to heat the fuel above to the incandescent state, and by passing through the incandescent mass of fuel the CO_2 is reduced to CO. The first portion or zone when the fuel is burned is called the combustion zone; the second zone, where the thick bed of incandescent coke is found, is the decomposition zone, a third zone, above the decomposition zone, is called the distallation zone, and consists of a layer of fresh fuel, fed in at the top of the producer. In the distallation zone we find, as the name implies, a distilling of the coal or a driving off of the volatile matter in the fuel, with the formation of tarry vapours containing the higher hydrocarbons, such as methane, ethylene, and other gases in the higher series. From a producer using air alone we would then obtain a mixture of gases containing CO as the chief combustible, methane and ethylene, with the other tarry vapours in small amounts, and in addition nitrogen from the air and a little CO_2 which passed through the decomposition zone unreduced.

As regards the reactions occurring on account of introducing steam with the air, in passing through the hot zone the steam is heated to a high temperature and decomposed into its constituent elements, hydrogen and oxygen. This is an endothermic reaction, and absorbs a large amount of heat. Thus, the temperature of the combustion zone is kept below the melting point of the ash, the temperature varying inversely as the amount of steam decomposed. By regulating the amount of steam introduced we can therefore regulate the temperature at which the combustion zone is working, which, by being kept slightly below the fusing point of the ash, will effectively prevent the formation of clinker. The hydrogen formed by decomposing the steam passes unchanged through the producer and mixes with the other gases, raising the percentage of combustibles, and, of course, diluting the nitrogen content. The oxygen formed in decomposition of the steam combines with more carbon, with the ultimate formation of more CO, which again brings up the percentage of combustibles.

From the results of much research on the correct temperature at which to work the combustion zone it has been fund that to operate a producer most efficiently the temperature of the combustion zone should never go below 1.125 degrees C. However, many coals form ash which fuses below this temperature, and in order to use this inferior coal the producer must be worked less efficiently and at a lower temperature than that given, in order to prevent the undesirable formation of clinker. This is a point which has been overlooked in almost all works or books on producer gas, but in practice it is found quite frequently, especially at the present time during the scarcity of coal, when through necessity poor grades are used.

Operation

The usual defect in producer operation, particularly of the hand-fed and operated type, is the fact that the coal is not fed in at sufficiently regular and frequent intervals, the result being that the furnaces are submitted to a regular cycle of excess gas, gradually diminishing to a correct mixture of gas and air, and thence eventually to a shortage of gas and excess of air above that required for complete combustion. It is within the author's knowledge that in tests conducted on gas-fired furnaces with hand-fed producers the chimney-gas analyses have ranged from 12 per cent. $CO.^2$, 4 per cent CO, and three per cent. O, at the time of firing the producer, down to 5 per cent. $CO._2$ and 14 per cent. O when the charge of coal was spent, and just previous to the next charge. The effect of this intermittent firing at long intervals on the furnace itself is that the furnace is flooded with gas to begin with, the temperature being lowered, and volumes of gas and smoke pour from the furnace doors and other openings.

The direct fuel waste under these conditions is very seious, and yet many old-school furnace-men are never satisfied unless this waste exists, the general impression being that they then know the furnace is full of hot gases. This of course, emphasises the need for systematic elementary instruction of furnace hands in the principles of combustion and fuel economy. Some reflection thus makes it clear that by feeding the producer by hand in this way ,only for a few moments during the cycle of conditions of gas supply is the plant working at its maximum efficiency, the chimney loss at the remainder of the period being anything up to 45 per cent of the heat value of the fuel used. It should, however, be stated that often these wasteful conditions are seriously accelerated by the regulation of the gas and air supply, careful regulation by the furnacemen being conspicuous by its absence.

Another frequent and serious fault discovered in hand-operated producers is the neglect displayed on the part of the average gas man to rectify channelling; that is to say, passages develop from the tuyeres to the fuel bed permitting free air to pass through and dilute the gas above the fuel bed as well as burning it to $CO._2$ and wastefully raising it in temperature. This is not the only result, for the channels provide an easy access for the blast;

consequently, less air passes through the fuel bed, and less combustible is generated, another bad feature being the clinkering which occurs due to the burning of the air and gas in the aforementioned channels.

It is easy to understand the gas man's aversion to poking, for nothing less than a 12ft. by 7-8 in. diameter poker is of any use. Maintaining the fuel bed in good condition entails its very frequent use, and the work is certainly laborious. The result is that little or no solidification of the fuel bed is attempted, and consequently numerous air channels are formed, which very often means that the temperature above the fuel bed rises to such an extent that the hopper bell is melted. Under such conditions the percentage of $Co._2$ is naturally very high. The only solution of the difficulty is the general adoption of mechanically fed and mechanically poked producers.

Another fault frequently met with is due to the want of systematic procedure in cleaning, particularly water-sealed producers. Frequently only the first 2ft. or so of the ashes are removed from the water seal, leaving the central portion undisturbed. Consequently, when dropping the fire the centre will not fall due to there being no space to receive it. Thus, the residue towards the centre sets like cement, requiring the application of sledge hammers for removal, and also in such cases the gas is poor due to the uneven state of the fuel and ash bed and the difficulty of preventing channelling. It should therefore be impressed on the gas man that each producer should be systematically cleaned right to the tuyere, as a clean producer works and makes good gas under normal conditions. To guarantee this cleaning, various mechanical devices are now in successful operation for performing this work.

Depth of Fuel Bed

In considering what the depth of fuel beds should be for a producer, points which must be taken into consideration are: (1) Nature of fuel as regards coking; (2) nature of fuel as regards melting point of ash; (3) nature of fuel as regards size; (4) type of blower; (5, rate of gasification; (6) method of agitation of fuel bed, either hand-poked or mechanically operated; (7) method of removing ashes.

For ideal conditions one would have a very thick fuel bed having about the following proportion: 18in. to 30in. of incandescent zone, and about 9 in. of fresh fuel as distillation zone. To obtain a bed of this dimension it would be necessary to have a non-caking or coking coal, with an ash which is of a very high melting point, and the fuel should be screened nuts. The blower should be one of ample capacity to furnish a large amount of air with a small amount of steam, as the thickness of the bed depends wholly on the amount of air which can be used to give a very high temperature at the bottom of the incandescent zone, where the intensified heat is carried upwards and used to heat up the incoming coal. The amount of heat made, of course, will determine the amount of thickness of the incandescent zone, as it heats up the incoming coal, driving off the volatile matter and later heating the coke to incandescence. If the ashes from the coal are of a low fusible nature this high temperature cannot be carried, as the ashes will fuse and clinker will result. The advantage of a thick incandescent zone is obvious. The longer time which the $Co._2$ has to be in contact with incandescent coke, the more it will be reduced to CO, thus reducing the incombustible gases to a minimum and utiliing the full carbon content of the fuel in the formation of combustible gases. The fuel must be of non-coking variety in order that the ditillation zone does not become a sticky mass, which would prevent the air from being blown through the producer, and would cut down the rate of gasification, thus, of course, lowering the depth of the incandescent zone. The distillation zone should be of such thickness that the temperature of the gases leaving the producer is about 1200 degrees F to work a producer in a very efficient manner. The heat then being kept inside the producer by the incoming coal, it is neither lost by radiation from the flues, nor is it wasted by being sent to the stack as in the case of regenerative furnaces, but it is used instead to drive off the volatile matter from the fuel.

Another advantage of a thick fuel bed is that it tends to give a very uniform gas in composition, the thickness of the bed being such that any slight variation in the amount of steam or air does not have any very great effect. Furthermore, since the top temperature gets considerably lower than in the average practice, a sudden dump of coal upon the bed will not give a sudden rush of the gases to the furnace and up the stack. It is seen that with a thick fuel bed and a low-temperature gas being involved, the volatile matter is driven off slowly and continuously over a thick amount of fuel, and the average value of the higher hydrocarbons is spread throughout the time between dumps. With a fuel which clinkers very easily due to its low melting ash, it is, of course, necessary to use more steam in the blast. This necessitates a thinner decomposition zone, and also a thinner distillation zone, but it is always best to work any producer and any fuel with as thick a bed as is possible under the existing conditions. It has been discovered after careful investigation that at least 90 percent of producers will be found to be carrying too thin a fuel bed, this being invariably due to the bad method of operation into which the gas man has fallen.

Mechanical Producers

During the last few years various attempts have been made to evolve a mechanical producer for the removal of the troubles previously referred to as being part of the hand-operated type. It therefore develops into producing a machine that gives: (1) An automatic method of feeding the fuel uniformly over the entire bed and in small amounts at a time; (2) a method of agitating the fire bed for the retention of a level surface, and the prevention of the formation of holes or mounds; (3) the automatic removal of the ash.

This question of mechanical producers has had particular attention in the United States, and various machines have been designed and are at present in successful operation, each of which has certain features which are of great interest, and the results obtained have been highly satisfactory. During the last eighteen months the author has been directly interested in the installation, testing, and working of the Chapman floating agitator with automatic feed. The general idea in connection with producers has been to design a producer that rotates—i.e., the whole of the producer casing, fire-brick lining, and bed,—the agitation being performed by either stationary pokers or swinging scrapers. The Chapman Engineering Company, however, diverted from this, as they concluded the correct method of agitation was to rotate the portion that did the work, thus removing the heavy work entailed in rotating the producer itself. The author then described the Chapman producer.

Capacity of Producers

This depends not only on the special type of producer, but also upon the quality of fuel used. The possibility of the ash in any coal determines its maximum rate of combustion on any producer. With a very fusible ash the rate of combustion must be reduced to make good gas continuously without excessive labour or much waste. With good-quality and low-ash coal, high in volatile, more may be gasified per square foot of grate area than with those less-marked "gas coals." Where fuels have an increase of ash or sulphur, or by a considerable amount of fine coal, the rate of gasification decreases, in many cases this not exceeding 6lb. per sq. ft. A deeper fuel bed is required for bituminous coal than for anthracite, the quantity gasified naturally varying with the quality. With an up-to-date mechanically operated producer 40lb. per sq. ft. area is often obtained, the gas being of excellent quality, and the figure of 25 lb. per ft. can be taken as a fair average.

Producer Fuels

Ignoring such substances as peat, wood, sawdust, etc., each of which is being continuously used for the production of gas, we find that anthracite, bituminous, and semi-bituminous coals are the ones usually employed, though lignite and brown coals are also now being utilised, the fixed carbon being the basis of producer action and gas yield. Coke is also employed, and particular mention of this is made in the section of the paper referring to slagging producers.

The fuel of the highest heating power is the best, for the use of lower grades means higher initial outlay in the plant

(due to the low gasification), more labor charges, greater loss of combustion in the ash, and greater difficulty in operating. In high-temperature work a high percentage of volatile hydrocarbons in the coal is desirable, a smaller percentage of coal being necessary. Lower-volatile semi-bituminous coals, say 20% volatile, work satisfactory. Strongly caking coals are objectionable, but freer-burning coking coals give good results.

The fuel should be graded to as nearly a uniform size as possible, thus assisting in handling and feeding the producer, nuts being excellent, while in the event of lump coal being supplied this should be broken through a 3-in screen.

Fine dusty fuels should be avoided, the result of using these being the formation of a compact bed, requiring a higher pressure of blast to penetrate, and thus carrying over dust which develops into a nuisance in congesting the flues, furnace regenerators, etc. Any portion of the bed that happens to be loose allows easy penetration, burning the gas and lowering the efficiency, or, again, if the resistance of the bed is too great the blast seeks the walls as place of least resistance, the gas becoming high in carbonic acid, with the result that the gas is worthless. Sulphur should be as low as possible, as when present as iron pyrites it fuses readily and forms very troublesome clinkers.

The amount of steam required varies with the quality of the coal gasified, especially with the melting point of the ash. Coal having a low melting ash takes about 0.42lb. of steam per pound of coal gasified. Coal with high-melting ash takes about 0.3lb. It can be generally taken as 0.35lb. of steam per pound of coal. One ton of coal per hour then needs 784lb. of steam or water evaporated per hour. The pressure required varies; with the primary nozzle in the blower using a ½in. nozle, about 54lb. pressure per sq. in. is recent experiments conducted in Ger- Using a 9-16-in nozzle, steam pressure for the same amount would be 47lb.

The temperature of the blast, (steam and air mixture) indicates the proportions of air and steam. Poor coal of low-melting ash needs high-blast temperature, hence more steam per ton of coal. "Back pressure" is the pressure in blast due to resistance of ashes in the coal, plus gas main pressure, and is generally about 3½in. water gauge The Champian blower works against 7-in. efficiently. The usual limits of blowers are 4-in. or 5-in.

Slagging Producers.

The question of slagging producers has not been considered to any extent in this country, but it is claimed from recent experements conducted in Germany and elsewhere on the Continent that excellent results are being obtained. The fuel used is coke, to which iron furnace slag is added as flux.

Recent successful experiments with this type of producer have been conducted at the works of the Georges-Marienhutte at Osnabruck. The gas obtained is remarkably dry, due to the fact that the blast is supplied by air only, no steam being admitted. This high heat value is due to the high percentage of CO, which approaches 50% whereas the percentage of CO_2 is low.

It is claimed as the main advantage of this type that flues with as high as 50% ash can be gasified. Naturally the fluxes have to be varied in quantity and description to suit the variable ash content. Low grade iron ores are used to advantage, which otherwise are no use for reduction. The cost of operating the producer is reduced by selling the pig iron thus obtained as a by-product, but the author is very doubtful of the success obtained in these sales.

At a certain German steel plant these producers were tried without the addition of iron, but it was discovered that the operation only worked satisfactorily for a short period; the slag became more viscous, and finally solidified, thus causing the producer to be stopped. Various methods were tried to prevent this. The first conclusions arrived at were that due to the slag getting in contact with the cold bottom of the producer a chilling effect occurred, and to alter this a separate chamber was built under the producer, but this unfortunately only lengthened the trouble without eliminating it. It was after this that a flux in the shape of pig iron ore was charged in with the fuel, after which no further trouble was met with in keeping the slag in a sufficiently molten state for tapping off.

One of the main difficulties, however, has been the problem of applying a producer of the type for the gasification of fines, the necessity for using air blown at comparatively high pressure causing fine particles to be blown out in suspension with the gas. This naturally caused trouble by filling up the generating chambers at the furnaces with dust, but although the area of the flue bed was considerably enlarged, thus reducing the velocity of the gas, the trouble could not be entirely eliminated by this method. However, a design has recently been developed, in which dust catchers are arranged at the top sides of the producer. As the velocity of the gas in these chambers is reduced, the particles deposit, and gravitate through pipes containing gates into the tuyeres, and are again blown into the producer.

The question of the application and design of this slagging type of producer is receiving a certain amount of attention in this country, but it is still in an experimental stage, while the question of slag always makes a troublesome proposition which, if possible, should be avoided, so many conditions occurring that may cause freezing. The question, however, is of great interest and it is possible at some later date that certain combinations in conjunction with producers of this kind will make vastly altered conditions possible in connection with gas production for commercial purpose.

"Hold tight. You'll go up in a short time." Some good advice to the business world from Racey.

Strong Steam Traps
Save Every Ounce of Steam

Strong Steam Traps automatically remove the condensation from the systems or machines to which they are connected.

The service rendered by Strong Steam Traps in respect to increased machine output at lesser cost, has resulted in the standardization of Strong Traps by a great many of the largest steam trap users in the world.

Our nearest Sales Office will send full information and prices on request.

98% of the Largest Central Stations Use

COPES
Boiler Feed Regulators

THERE can be no doubt that they employ the most experienced designers and expert engineering talent to build and operate their plants.

These leaders in steam production are vitally concerned in costs. Their profits are directly dependent upon how cheaply they can generate steam.

Naturally the subject of boiler feeding was thoroughly analyzed by them, before determining the most satisfactory and dependable methods.

They have tried hand feeding and so-called mechanical regulators that are controlled by floats and operated through pilot valves, springs and diagrams.

Evidently they have found these methods to be wasting.

And this is precisely the reason why 98% of the largest central stations use COPES Boiler Feed Regulators.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force can not replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every month will keep you posted on the latest developments for power house equipment.

? Who was the Third Man?

WHEN the retirement of Sir Robert Borden as Premier of Canada was first announced, three outstanding men were considered as his possible successors. Their names were displayed prominently in every Canadian newspaper. The present Premier was of course one of the men mentioned. Sir Geo. Foster another. Who was the third man? You would remember him no doubt if his name were displayed prominently in the daily press to-day—but he has retired from the political arena, and his name is seldom mentioned.

How easily names slip from the memory when they cease to be given publicity.

There is a lesson here. If you wish your name and the name of your products to be remembered, you must give them constant publicity.

The prudent manufacturer of machine tools, power plant equipment, or industrial supplies of any kind places his name and the name of his products where they will be seen and remembered to best advantage: **in reliable technical newspapers.**

Reliable technical newspapers in Canada are those included as members of Canadian National Newspapers and Periodicals Association. Their circulation is bona-fide and their editorial practice is carefully guarded, in fact their whole policy must conform to the highest standards else they would not be eligible to membership in the association.

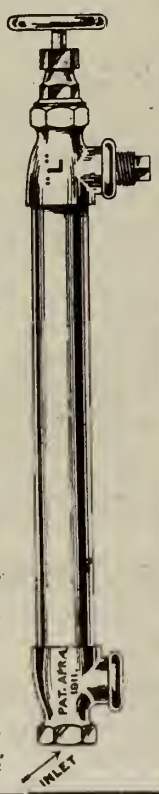
Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt



The Long Patent Steam Trap

Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admissions of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds.

Being open at etarting, it cannot become air bound, this doing away with air cocks or vents — Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and lese power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

Jones "A-C" Stokers

minimize coal cost

Jones "A-C" Stokers cut coal costs in two ways—by burning less coal, and by burning cheaper coal. The full value of the Jones under-feed principle is realized by: automatic control of fuel and air, large capacity retorts, absence of clinker on side and bridge walls, mechanical (not gravity) feed, and "automatic-cleaning."

give greater capacity

Capacity is a prime requisite of high-duty stoking. Jones "A-C" retorts hold a big fuel reserve for quick pick-up. Elimination of ignition arches permits hard driving. Individual control of retorts provides for emergency load conditions. Automatic air and fuel regulation insures high efficiency while carrying heavy overloads.

cut labor cost

The simplicity of the Jones "A-C", and the automatic regulation, minimizes operating labor. "Automatic-cleaning" reduces working of fires. The rugged simplicity cuts repairs and the labor necessary for making repairs. The simple balanced dump plate eliminates high-maintenance complications. There are no working parts in the fire. This also minimizes repairs.

And every Jones Installation proves it!

Many engineers argue that a stoker may be a "howling" success in one plant and an utter failure in another.

This is undoubtedly true. How, then, can you determine just what bearing tests results, made in another plant, have on your own plant? First consider a few typical reports from plants equipped with Jones "A-C" Stokers:

A big hotel at Saint Andrews-by-the-Sea cites a Co Recorder chart showing remarkable combustion efficiency A Canadian paper mill calls attention to big economy burning paper mill refuse ("hog fuel"). Another plant sends a flow meter chart showing 297% of boiler rating for four hours. Other plants report five months of continuous overloads up to 250% of rating.

But these records would not be so significant if it were not for one important fact; the plant that stresscs high efficiency can carry the heavy overloads boasted by the plant that reported them. The plant that is meeting heavy peaks can rival the record of the plant that reports high efficiency. Any of these plants can burn as low grade fuel as any other Jones equipped plant. Why? Simply because the reasons for good performance are the same in each case——because the **design** and **construction** of Jones Stokers is basically **correct.**

So Jones performance records show what can be realized from any Jones Stoker in **any** plant—which includes **your** plant.

Know the basic features behind the unmatched performance of Jones "A-C" Stokers. The new book: "Ten Points of Jones Superiority" goes into detail. Write for your copy.

In this plant nine 823 H. P. boilers are equipped with "A-C" Stokers of 8 retorts each. Originally 7 boilers were equipped; later stokers for two more boilers were ordered.

Canadians and sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized as the Under-Feed Stoker Co., of Canada, Ltd., and the reorganization makes available for Canadian Power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

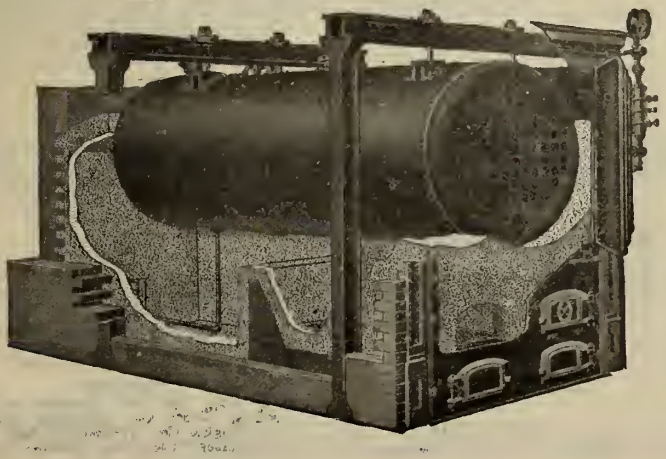
BUILD YOUR NEXT BOILER FURNACE LINING LIKE THIS

With Betson's Plastic Fire Brick it is easy for anyone, even without experience. No special forms or tools are necessary to lay up a one-piece, jointless furnace lining that is air and gas tight and free from the destructive effects of gases getting back of the fire brick lining, or expansion and contraction. No separate fire brick, tiles or blocks, and no clay mortar joints to give way.

Write for informing pamphlet.

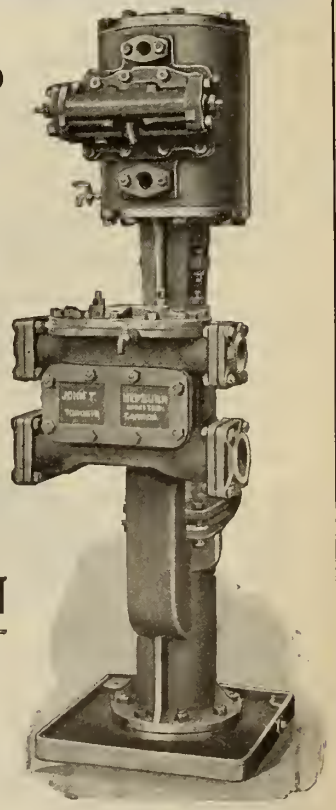
BETSON PLASTIC FIREBRICK CO., Inc.,
P. O. Box 386-6 — Rome, N. Y.

Canadian Distributor:
INTERNATIONAL CHEMICAL CO.
14-6 Lombard St., Toronto, Ontario, Canada



Your Ram Pump
Should Possess These Features

1. Should have ample capacity to handle high temperature water at high steam pressures.
2. Should require a minimum of packing and hence minimum chance of leakage.
3. Should occupy a minimum of space.
4. Should be automatic Draining.
5. Should run with full stroke even at slowest speed.
6. Should have no extraneous levers or tappets, to get out of order.
7. All parts should be accessible.



HEPBURN
Patent Pumps

give you all these features and many additional ones. Let us tell you all about them. We will be glad to have you write us, or, better still, call to see our Plant.

How are you treating your fire-brick?

—*their life depends upon it*

WHEN flame and heat get directly in between your fire-brick, the brick can't last as long as when only one surface of each brick is exposed.

When you use fire-clay or cements that melt, crumble or disintegrate, the bond between the brick gives way and falls out. You haven't treated your fire-brick as you should, and you don't get maximum service from them.

Johns-Manville Refractory Cement, when used as recommended, makes a strong bond between the brick that doesn't melt, crack or fall out. And Johns-Manville Refractory Cement applied also to the surface of the fire-brick makes a good brick better.

Write the nearest branch for information about Johns-Manville Refractory Cements numbers 26, 31 and 32.

For extremely high temperatures—above 3200°F—ask about Johns-Manville Super-Refractories.

CANADIAN
JOHNS-MANVILLE
CO., LIMITED

Vancouver, Hamilton,
Ottawa, Windsor

Read how vitally this cement affects the life of your fire-brick.

Saving invisible waste

The heat lost thru bare or improperly insulated pipes frequently escapes unnoticed, because this waste is not visible.

The remedy is Johns-Manville Asbesto-Sponge Felted, the most efficient commercial insulation known—and the most durable because it is a felted, rather than a molded material. It will withstand rough handling and hard abuse. It maintains its efficiency longer than any other commercial insulation, and in many cases outlasts the steam pipe it covers.

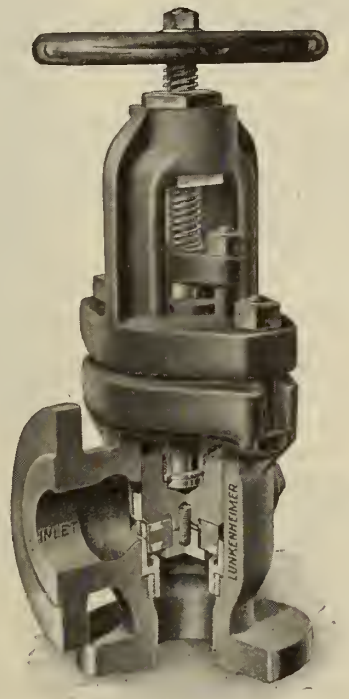
LUNKENHEIMER
"Duro" Blow-off Valves



"DURO" Blow-off Valves effectively meet the requirements of Boiler blow-off service.

The "DURO" *self-cleansing seat* insures tightness; reduces to a minimum the wear on the seating faces, prolongs their life, and prevents leakage which would impair the economical operation of the boiler plant.

The "DURO" disc is reversible, being provided with two seating faces, and the disc, together with all other parts are renewable. These advantages peculiar to "DURO" Blow-off Valves are the result of years of experience, which, combined with high quality materials and the LUNKENHEIMER method of manufacture, make them valves of unexcelled merit.

The LUNKENHEIMER Distributor in your locality can supply your valve needs. Acquaint him with the operating conditions of your plant. This knowledge will enable him to anticipate your requirements, preventing delay and possible shut-down when an emergency arises.

EQUIP WITH "DURO" BLOW-OFF VALVES.

ELESCO

ELESCO SUPERHEATER INSTALLATION IN STIRLING TYPE BOILER

Header and Units are arranged for easy accessibility outside the boiler setting. There are no joints inside the boiler.

Meeting The Demand For Greater Power

Public utilities are beginning to feel the demand for greater power and production. The condition will be more serious when industry resumes, unless provision is made to meet the demand which is sure to come.

Additional power may be gained by installing new boilers, or by increasing the efficiency and capacity of existing boilers through the installation of Elesco Superheaters.

With Elesco Superheaters, the additional capacity may be had at one-fifth the cost of new boilers.

Elesco Superheaters are easily applied, without change to boiler settings. Now is the time to install them. Our engineers, working with yours, will be glad to give you a detailed report showing exactly how much additional capacity you can get and how much fuel you can save by equipping your boilers with Elesco Superheaters.

THE SUPERHEATER CO., Limited

Transportation Bldg., Montreal **Works at Sherbrooke, Quebec**

De Laval velocity-stage turbine driving centrifugal pump; 3,000 gal. per min. against 231 ft. head, using steam at 80-lb. pressure.

A De Laval General Service Pump

THIS De Laval turbine-driven centrifugal pump is as reliable as a motor-driven pump. It gives satisfactory efficiency, due to the use of hand-controlled nozzle valves, and can be adapted to quite a range of steam pressure. The speed is controlled by a powerful and accurate governor. All working parts are accessible upon lifting the casing covers, and may be lifted out after removing the bearing caps. It is recommended where continuous operation is required under severe conditions.

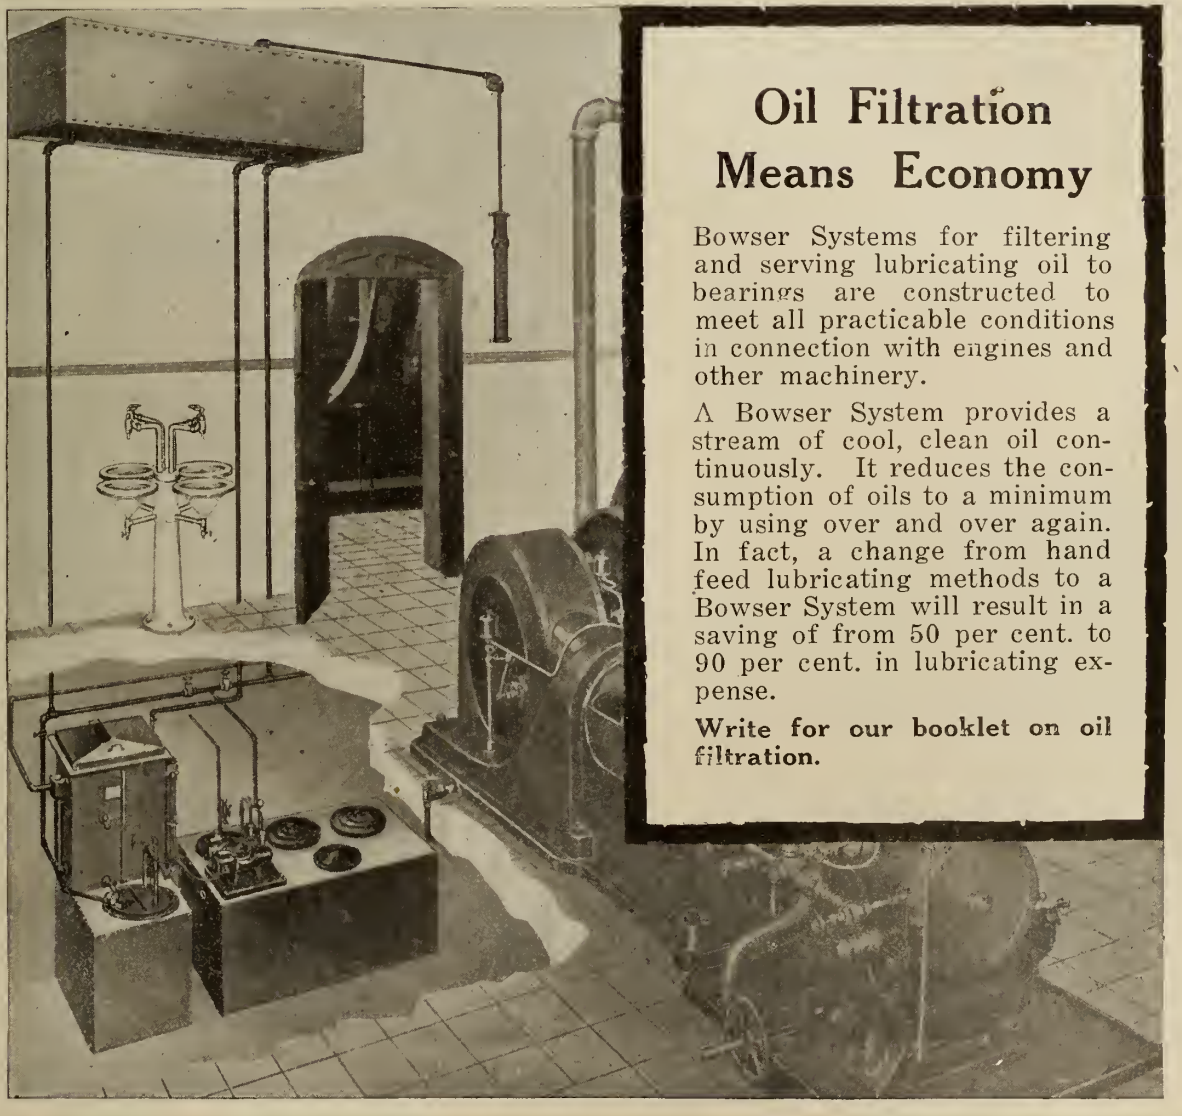
BOWSER

ESTABLISHED 1885



Oil Filtration Means Economy

Bowser Systems for filtering and serving lubricating oil to bearings are constructed to meet all practicable conditions in connection with engines and other machinery.

A Bowser System provides a stream of cool, clean oil continuously. It reduces the consumption of oils to a minimum by using over and over again. In fact, a change from hand feed lubricating methods to a Bowser System will result in a saving of from 50 per cent. to 90 per cent. in lubricating expense.

Write for our booklet on oil filtration.

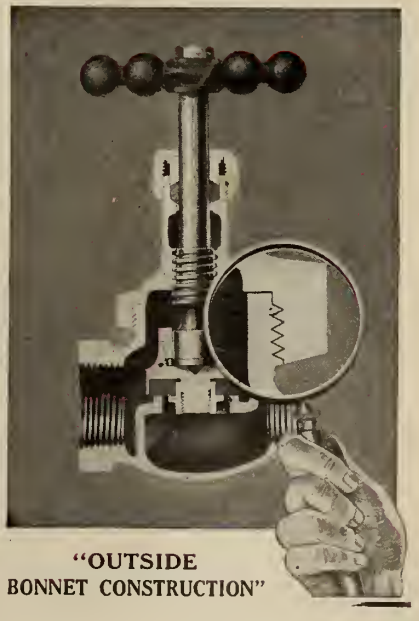
TRADE PENBERTHY MARK.

A SAFE GUIDE IN VALVE BUYING

"Be Sure This Name is On the Valve You Buy"

In the illustration to the right we have marked with the circle the one big improvement in our valves over other makes, viz: "THE OUTSIDE BONNET CONSTRUCTION." The bonnet *does not* screw *into* the body of the valve. It fastens to it by *Outside* threads on the body, which threads never come in contact with the corrosive action of the steam and water. They are *away* from it. The result is, the valve bonnet and body can always be taken apart without strain or injury. This construction also prevents spreading of bonnet end of body when screwing down the bonnet tight. It's SAFE, SURE and STRONG.

For your protection against substitutes always look for our name cast on the body of every genuine Penberthy Valve.



"OUTSIDE BONNET CONSTRUCTION"

We Make:

The Compodisk Line (with the Renewable Disc)
Gov't approved for 175 lbs. steam pressure

The Regrinding Line (with the Metal Disc)
Gov't approved for 200 lbs. steam pressure

Brass Gate Valves (with the solid Wedge Disc)
Gov't approved for 150 lbs. steam pressure

Strong Where Others are Weak

USED BY THE BEST ENGINEERS-

Jenkins Valves

KIPAWA PLANT OF THE RIORDON COMPANY, LIMITED.

Functioning Every Day In This Big Plant at Kipawa

JENKINS
CAST STEEL GATE VALVE
Extra Heavy
Outside Screw and Yoke
Flanged
For Super Heated
Steam Service

Realizing what an important part good valves play in the matter of efficient plant operation, the Riordon Company selected Jenkins Diamond Marked Valves for their big Kipawa plant.

Jenkins Cast Steel Extra Heavy Gate, Globe and Check Valves with Genuine Monel Metal Mountings, specially designed for superheated steam service, play an important part in the steam distribution lines of this modern plant.

All over the Dominion, in plants where production is big and distribution wide, Jenkins Valves are furnishing dependable trouble-free service all day and every day throughout the year.

Know genuine Jenkins Valves by the name and the Diamond Mark cast on the body. At supply houses everywhere.

Perfect Service Gasket Material

Guaranteed to make a Tight Joint wherever a Permanent Gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown.

DURABLA
TRADE MARK REGISTERED

Strength; Goodness; Quality - these features distinguish Durabla Gaskets.

DURABLA Sheets can be rolled and unrolled; it never dries out or opens up.

DURABLA Compressed Asbestos Fibre Gasket Material is a guaranteed product that can be used as a standard for all Gasket work. DURABLA Gaskets make tight joints on Steam, Water, Oil, Ammonia and Acids at all temperatures and pressures.

DURABLA is not affected by vibration or condensat on. It will not burn out, blow out or pulp at the points.

Let us send you a trial sample. Made in stock sizes 36 in. wide x 144 in. long, and 48 in. wide x 144 in. long, in thicknesses of 1-64, 1-32, 1-16, 3-32, 1-8.

Orders Filled Promptly.

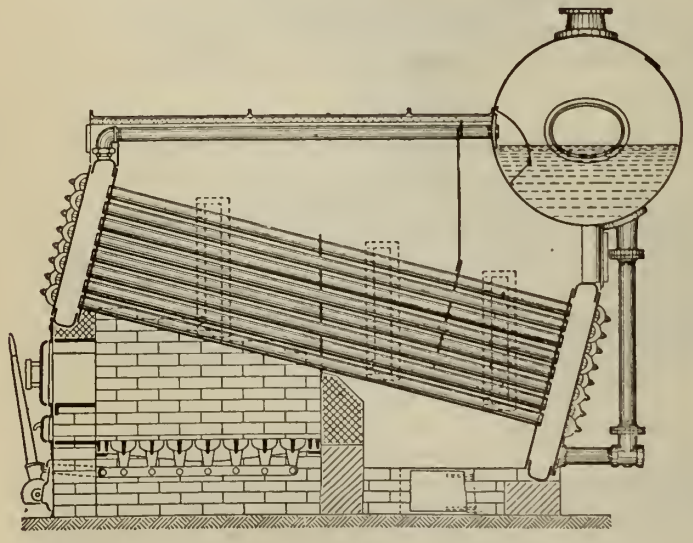
DURABLA

The Victory Heating Boiler



Is a water-tube boiler designed for heating, and is the safest boiler that can be used.

It has a steel case lined with asbestos and firebrick and requires no brick setting.

It may be shipped knocked down and taken into a building through ordinary doors.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

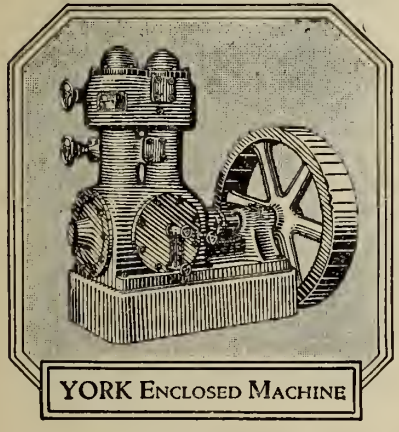
YORK



YORK ENCLOSED MACHINE

RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

YORK, PA., U. S. A.

There is a YORK Plant to fit Your Business

Building a one-piece furnace lining without special forms or tools—No separate brick and no clay mortar joints.

Install New Boiler Furnace Linings and Baffles

Now, is the ideal time to re-line your boiler furnace, or put in new sloping baffles. Then you will avoid annoying delays and loss of time later on.

Permanent One-piece Linings and Baffles of

BETSON'S
PLASTIC FIRE BRICK

are easily installed without special forms or tools, even with inexperienced help.

The high temperatures reached by modern boiler furnaces, cause rapid disintegration of clay mortar joints, followed by complete destruction of the fire brick linings, arches, etc.

A solid one-piece lining, including front and back arches, side walls and baffles, costs but little to install in any make or type of boiler, and saves fuel, annoying shut-downs, costly repairs, and increases the amount of usable power from the fuel you pay for.

Complete details of the uses, methods of installing, how to order, measurement blanks, etc., are contained in a booklet of information which we will gladly send you. Tell us the individual to whom it should be addressed.

Efficient — But Simple

THE De Laval velocity-stage turbine is made of few, simple and readily accessible parts. The casing is divided horizontally in the plane of the centre line of the shaft, and the casing cover is also divided vertically, so that it is possible to get at the internal parts without disconnecting piping. The wheels and shafts are made of high-grade alloy steels, and the buckets and reversing vanes of drop forgings. The governing mechanism is effective and accurate.

Maximum efficiency at various loads is provided for by hand-controlled nozzle valves. De Laval velocity-stage turbines are ideal for direct connection to centrifugal pumps, such as boiler feeders, elevator pumps, service pumps, high pressure blowers and compressors, etc., and for driving small A.C. and D.C. generators. By the use of the De Laval speed-reducing gear, they are also applied for driving large standard-speed generators, low pressure fans and blowers, belt and rope drive, etc.

This Bulletin Points a Way to Boiler-room Economy

The crying need of the world to-day is ECONOMY—and still MORE ECONOMY—coupled with greater efficiency in production.

There is a host of ways to arrive at the much desired result, of course.

One of them—a tremendous help in reducing boiler-room losses—is the Vulcan Soot Cleaner. It reduces stack temperature, increases steam capacity and production, and decreases fuel consumption.

Send for a Vulcan Bulletin and let it show you how and why Vulcan Soot Cleaners are a vital necessity in the modern boiler-room.

The Bulletin shown describes the Vulcan Soot Cleaner for Stirling boilers. Other Bulletins are: No. 541, for B. & W. boilers; No. 547, Wickes; No. 550, Connelly, Badenhausen and Erie City Vertical; No. 552, Edge Moor; No. 556, Keeler, Geary and Union; No. 534, Return Tubular.

Eliminates Air
From Feed Water Heaters

The Des Moines City Railway Company has a circulating system of the siphon type, in connection with their condenser.

In order to reduce the amount of power used by the circulating pumps and also to keep the tubes in upper part of condenser shell free from air, they installed a

Fisher Automatic Air Trap
(Type 30)

on the water box of the condenser. The pressure on water box varies from one to two pounds above atmospheric pressure to several inches below, and condenser pressure is maintained at from one to two inches absolute pressure. This arrangement keeps circulating systems free from air at all times and prevents flow of circulating water from system to steam side of condenser.

They also have a vacuum heating system supplied from main boiler plant, returns being pumped direct to feed water heaters. They installed one of these air traps on air chamber of vacuum pump, which eliminated the necessity for frequent venting by hand and prevented waste of exhaust steam.

The Fisher Automatic Air Trap is adapted to many other uses. Let us send you our Bulletin No. 1001 which fully describes this highly efficient device.

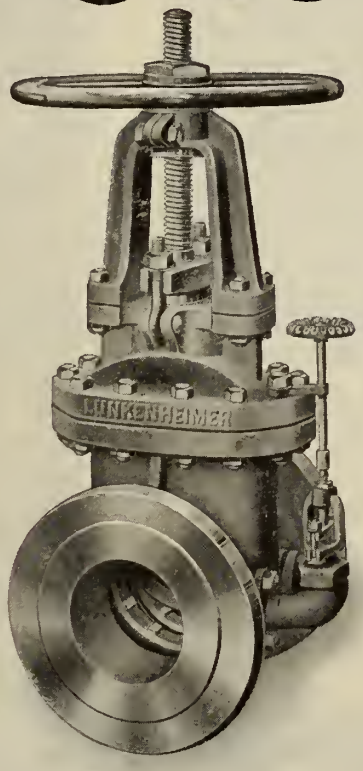
LUNKENHEIMER

"Victor" Gate Valves



Dependable performance is the service record of LUNKENHEIMER Iron Body Bronze Mounted "VICTOR" Gate Valves. The "VICTOR" solid wedge disc, double-faced and guided in its travel, is the most practical design of Gate Valve construction. It eliminates "dragging" across the seatring faces and the consequent wear prevalent in valves employing loose parts.

Highest quality materials, coupled with the LUNKENHEIMER method of manufacture; bearings bronze bushed to minimize wear; all parts, including the seatrings renewable, and the indestructible gasket between the bonnet and body flanges, all tend to enhance their value and insure longevity.

Made in both Inside Screw Stationary Stem and Outside Screw Rising Stem types, in four weights for pressures ranging from 100 to 250 pounds. Also in Quick-opening Sliding Stem type for pressures from 125 to 50 pounds, depending on the size.

"VICTOR" Gate Valves are also made in Bronze for pressures up to 250 pounds and in Cast Steel for pressures up to 350 pounds and temperatures to 800° F.

Specify LUNKENHEIMER "VICTOR" GATE VALVES and insist on their installation.

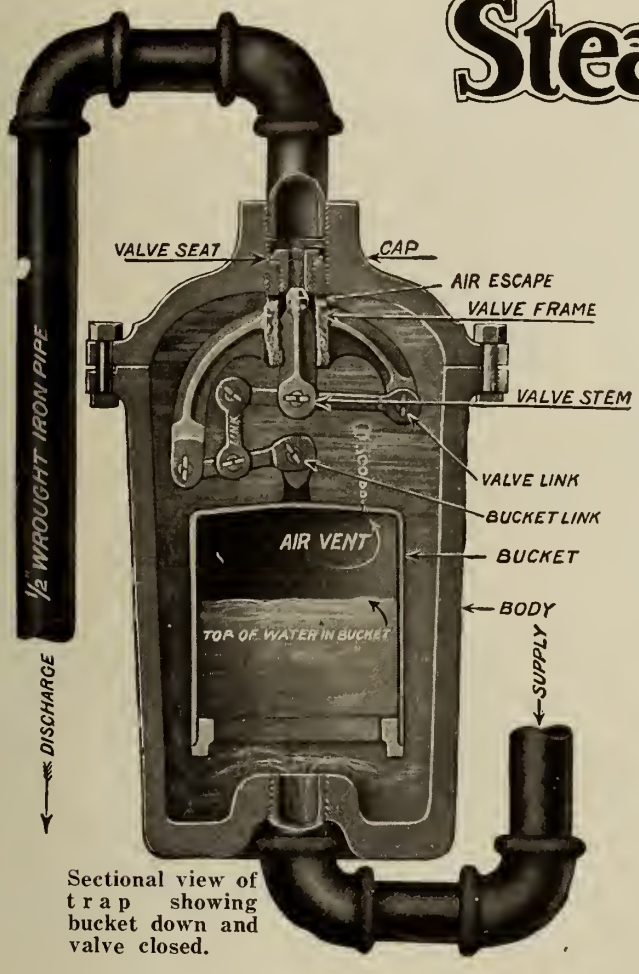
Armstrong Steam Trap



Sectional view of trap showing bucket down and valve closed.

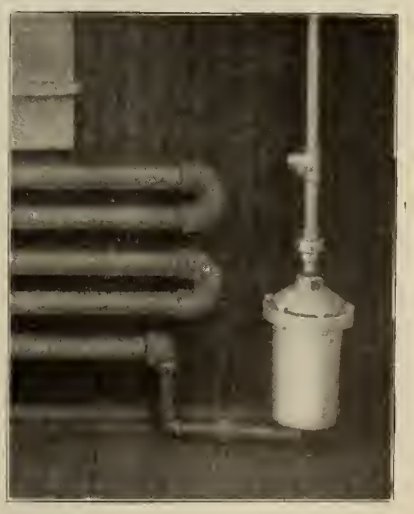
The Best Trap to Handle Condensation— Its Principle is Different

THE exclusive "Inverted Submerged Bucket" feature of the Armstrong Steam Trap mark it preeminently as the **best** trap to handle your condensation.

It absolutely will not pass steam. It will not become air-bound and is least affected by sediment, scale or oil. It requires a minimum of attention and upkeep; is compact, easily installed, and is of ample capacity for the work. Furthermore it is an economical investment, cost, capacity and upkeep considered.

THE Armstrong Trap is small in size and light in weight compared with the ordinary trap. It is easily connected and may be suspended on a pipe line; neither foundations nor pits are required. This and the fact that an Armstrong is self-cleaning and operates with little attention, is the reason for its widespread popularity with big power plants.

Write for details of our guarantee and 60-day offer



A No. 2 Armstrong Trap draining a low pressure coil in Fairbanks-Morse & Co.'s plant. Note the water seal at the trap. Holes in the floor are unnecessary as Armstrong Traps need not be set below the coil.

The real test of stoker service is the unexpected

In this plant nine 823 H. P. boilers are equipped with Jones "A-C" Stokers of 8 retorts each. The original order covered 7 boilers. Stokers for two more boilers were ordered later.

Write for "Ten Points of Jones Superiority"

How the Jones "A-C" meets the unexpected conditions that test a stoker's ability is told in this new book. The description of Jones "A-C" design and construction is complete but not long; thorough, but not highly technical. Where shall we send your copy?

Jones

Will Your Stokers Weather These "Ifs"?

TEST runs rate a stoker's efficiency—but there's nothing like the rough going of daily service to test a stoker's ability. After all, it's ability to cope with the unexpected that means most from the practical standpoint, for in power plants it seems the unexpected always happens!

Consider a few of the emergencies that are almost bound to arise in the average plant in the course of a year—the unannounced and unexpected "ifs." Will your stokers weather these "ifs"?

if —there comes a sudden demand for multiplied steam output—perhaps a boiler has been unexpectedly forced off the line—what then? Will you be at the mercy of ignition arches in meeting the peak load? Or will you depend on a stoker each retort of which is subject to the same rate of fuel feed? You can't expect best results if you do.

In a Jones equipped plant this emergency is easily met. The greater capacity of the retorts insures a large fuel reserve, so that even at highest over-rating the coal is completely volatilized *in the retort.* Eight ranges of speed of the Cole Automatic Valve (which actuates each steam ram) permit any rate of coal supply. And the rugged simplicity of the stoker itself affords stamina to withstand continuous forcing.

if —under unusual conditions, holes in the fire or uneven burning develop—have you a simple way of correcting such an error?

The operator of the Jones "A-C" has at his command an exclusive feature for meeting this emergency—individual control of retorts. Any portion of the fire can be accelerated or retarded at will. Individual control of retorts is practically a stoker essential, yet it is possible only in the Jones "A-C"—an inherent feature of Jones design!

if —foreign substance enters the coal hopper. Will it mean breakage and complete shutdown, or at least sheared pins and temporary shutdown when the stoker is most needed?

Any substance, such as wood or tramp iron, entering the Jones "A-C" hopper can cause no real damage. It merely stops the steam ram momentarily while the obstructing substance is quickly removed through the door in the hopper throat.

if —your fuel market changes over night, are you at the mercy of the mines?

Or can you call on these features (as every Jones-fired plant can): high, air-cooled side tuyeres to prevent clinker formation on side walls (when the coal is of stubborn clinkering tendency); automatic control of fuel and air (assuring correct ratio of fuel and air for efficient combustion); automatic-cleaning; individual control of retorts—to mention a few outstanding advantages.

If—but the whole story cannot be printed in limited space. You will find it in the book described on the opposite page.

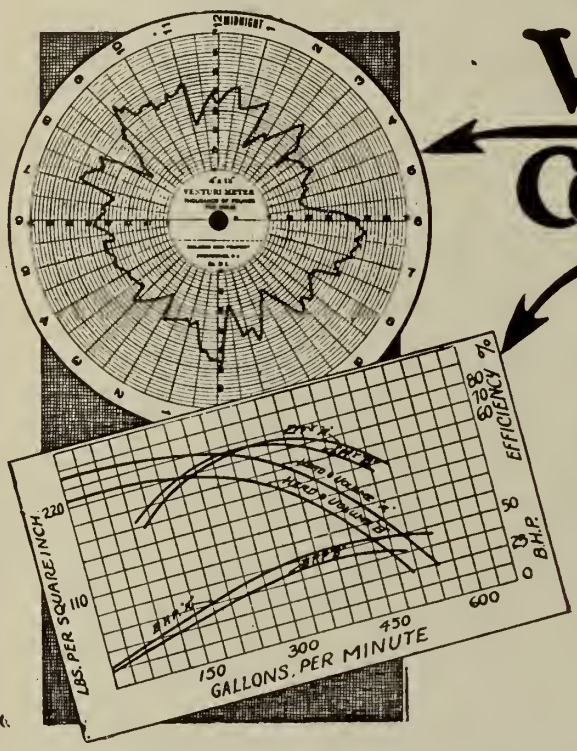
Variable Volume
Constant Efficiency



THE REES RoTURBo — A Centrifugal Pump for Any Service

IN the "Rees-RoTURBo" we have the very latest development in centrifugal pump design. The disadvantages of the ordinary pump have been entirely overcome and it meets perfectly the conditions of to-day for high efficiency.

The fluid velocities are low, reducing friction losses to a minimum, and there is no wear even from gritty water, and high permanent efficiency is maintained. This means that the "Rees-RoTURBo" is ideal for multi-stage operation and may be said to be a pump for any service.

Should there be any point on which you would like to be enlightened, our engineering department is always at your service and without any obligation on your part we heartily invite enquiries.

Published Semi-Monthly

A 200 h.p. Uniflow Steam Engine

This Engine Manufactured by Galloways Ltd., Manchester, Has a Novel High Speed Valve Gear and Compression Release Which Were Designed by Mr. Pilling, General Manager of the Firm

LAST year Power House published an article on the Uniflow engine together with some comment on a discussion then proceeding in the pages of the "Engineer," of London. Through the courtesy of the same publication, we are now enabled to publish a description of a 200 h.p. engine of this type recently built by Galloways Ltd., Manchester, Eng. The most novel features in this engine are a shockless high-speed valve gear and a compression release device designed by Mr. Henry Pilling, the general manager of the firm. In other respects the general features of the engine follow orthodox uniflow principles; that is to say, the steam is admitted at the ends of the cylinders and is exhausted through a ring of ports midway in the cylinder walls, the ports being uncovered by the piston when it reaches about 90 per cent. of the working stroke and covered again at about 10 per cent. of the return or compression stroke. The advantages claimed for this arrangement are, of course, well known to mechanical engineers. The steam ports and cylinder walls adjacent to them are not subjected to the cooling action of exhaust steam rushing past them, while the exhaust ports are not exposed to live steam. In this manner cyclical fluctuations of temperature in the cylinder walls are greatly reduced; the temperature from the inlet to the exhaust portions falls gradually and surface condensation is prevented.

In the uniflow engine, as the whole of the expansion of the steam occurs in one cylinder, the cut-off takes place exceptionally early, actually at about 7½ to 10 per cent. at full load. The steam valve has, therefore, to be opened and closed again while the crank travels through from 25 deg. to 35 deg., or in one-fortieth to one-thirtieth of a second when the engine is making 160 revolutions per minute. The new hydraulic valve gear which Mr. Pilling has invented performs the opening and closing operations quietly and efficiently, joints and pins and other moving parts which are liable to wear being conspicuous by their absence.

Another characteristic feature of the uniflow engine is the high compression in the cylinder, which is brought about by the early covering of the exhaust ports. The clearance volume is such as to limit the compression to a pre-determined maximum when the engine is operating on a normal vacuum. The clearance volume is usually from 2 to 3 per cent. of the piston's displacement. With the clearance space fixed, therefore, it is obvious that a poor vacuum will cause an increase of compression in the cylinder, which might become excessive and dangerous if suitable preventive mechanism is not provided. In the engine under notice an automatic compression release device of original design is provided.

Fig. 1 is a sectional elevation, Fig. 2 gives a section of the cylinder and of the hydraulic valve gear, Fig. 3 shows the arrangement of the automatic exhaust gear, and Fig. 4 shows a set of indicator diagrams which speak for themselves. The engine is one of three intended for driving centrifugal pumps employed for drainage purposes in South America. The rated full load is 200 brake horse-power, the diameter of the cylinder 20in., stroke 24in., steam pressure at the stop valve 160 lb. per square inch, and the superheat 120 deg. Fah. The vacuum is obtained by a jet condenser and air pump driven from the engine crank shaft. The bed frame is a single casting supporting the two main bearings and the bored crosshead guide. In this frame the metal is disposed well along the lines of stress, the side walls being high. The bed frame is rigidly bolted to the foundation and the connection between the cylinder and the frame is by a circular spigoted joint. Being of comparatively small size, the

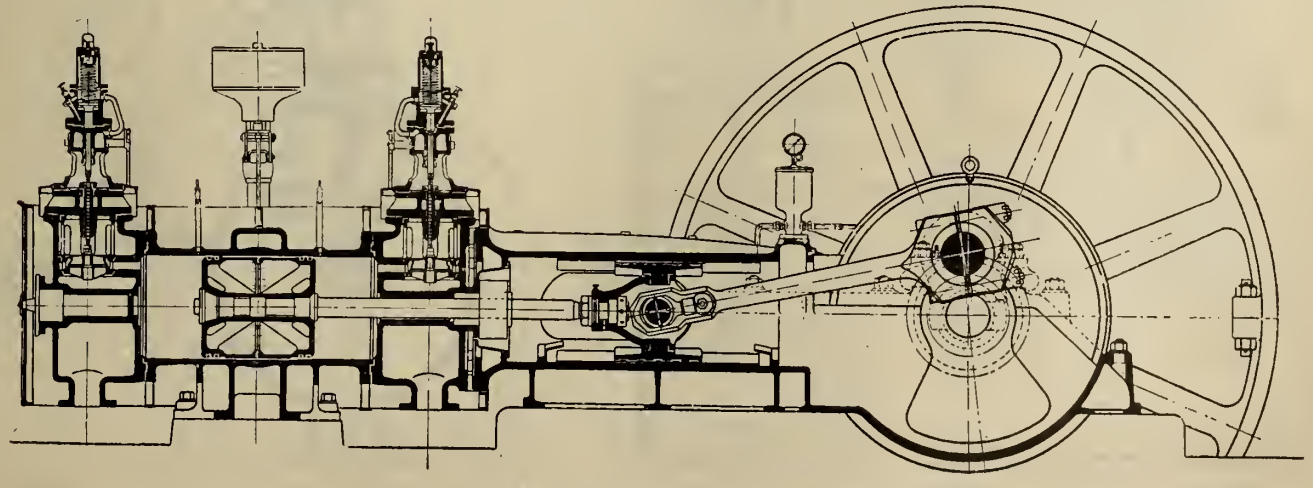

Fig. 1.—Sectional elevation of 200 H.P. Uniflow engine.

cylinder in this case is not of the patented built-up form of construction which has been adopted by Galloways for large cylinders. The cylinder casting the piston allowances are of course inner surface of the cylinder, as well as the piston rings can be inspected without moving the cylinder covers or piston. In boring the cylinders and turning the piston allowanres are of course made for the temperature differences which will occur in working, so that the clearance at all points of the stroke will be as uniform as possible. Each cylinder cover also acts as a valve chest and the steam ports are thus as short and direct as possible. The covers are steam jacketed, and in order to prevent the conduction of heat from the front cover to the bed frame the contact between these parts is restricted to pads or projections registering in the bed frame.

The piston—Fig. 1—is made in two parts, each with deep bosses fitting on the piston-rod. The two parts are spigoted near the outer cylindrical surface and held firmly together by conical faced nuts on the piston-rod. It will be seen from the sectional elevation that the steam valves are double seated. They are made of cast iron and of comparatively shallow depth, to give steam tightness under high temperatures. The new valve gear, Fig. 2, by which the steam valves are operated is a simple piece of mechanism. In this gear oil under pressure is applied below the plunger A, connected to the valve spindle B, and lifts the valve, which seats itself again by the action of a spring and dashpot C, when the fluid pressure is released. An eccentric on the lay shaft operates the ram D of an oil pump arranged in the valve bonnet. The pump ram is hollow and has a ring of slots or ports E, which at certain parts of the travel may be covered by a sleeve F surrounding the pump ram, the axial position of this sleeve being controlled by the governor. On the up-stroke of the pump oil is forced into the pressure chamber below the plunger, thus raising the plunger and the steam valve. At a point determined by the position of the governor the ports in the hollow pump ram overrun the sleeve and the oil escapes through the ports back into an oil reservoir. The steam valve is now free to close under the combined action of the spring and the dashpot piston, the seating of the valve being both rapidly and quietly performed.

We have had the opportunity of seeing the valve gear in operation with the engine running at 160 revolutions per minute. It was remarkably effective, giving a perfect control of the cut-off at any point from zero to about 60 per cent. of the stroke, and it operates with absolute silence. The prominent features of the valve gear are its compactness and the small amount of power required to operate it. The indicator diagrams serve to show how delicately the gear acts. They were taken by varying the position of the governor sleeve by hand while the pencil was kept continuously on the paper.

The other feature of special interest is the automatic compression release gear shown in Fig. 3. From the drawing it will be seen that two supplementary exhaust valves G H of the mushroom type are arranged on the side of the cylinder. These valves open inwards and are kept normally closed by the springs J K which act in conjunction with the pressure of the steam. On the engine lay shaft is a sleeve L carrying two cams M N of tapering form, which are capable of longitudinal movement on the shaft. The axial position of the cams is made to correspond automatically with the vacuum in the condenser by a spring controlled piston O, of a small cylinder P, mounted at the end of the lay shaft. One end of the cylinder is open to the atmosphere and the other to the condenser. The piston operates the cams by means of the rod R. Under normal conditions of vacuum the small end of each cam is just clear of the roller on the supplementary exhaust valve stem and the valve remains seated; but if the pressure in the condenser rises, the piston in the vacuum cylinder moves out and by means of the rod R the cams move axially, so that they allow the exhaust valve to open during a portion of the compression stroke, as shown in the drawing, Fig. 3. The amount and duration of the valve opening depend exactly on the axial position of the cams and thus increase as the back pressure rises. It should be noted that under normal vacuum the valves, valve guides, and rollers are absolutely out of action. The gear has thus few moving parts, and absorbs the minimum of power. As the engine operates its own air pump it has to start up without vacuum, and this gear gives full relief of compression until a vacuum is established, then permitting the compression to increase until the full compression at normal vacuum is reached. This means that the engine need only be barred round to the starting position after which starting is effected entirely by opening the steam stop valve. We had an opportunity of witnessing the operation of the compression release gear and can testify to its efficiency, both at starting and when the vacuum was purposely destroyed by admitting air through the "vacuum breaker" valve.

A short preliminary trial of the engine was carried out at Galloway's works before shipment. The engine was run at full load and speed, the power generated being measured by a

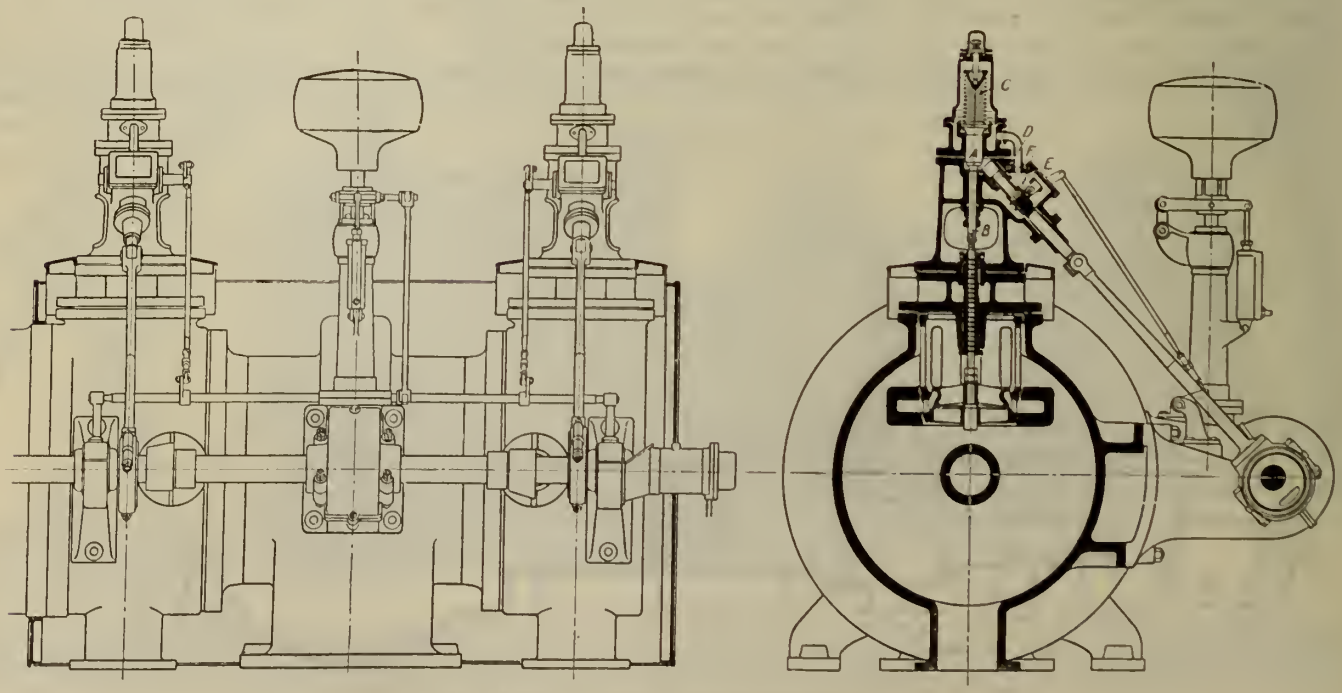

Fig. 2.—Side elevation and cross section.

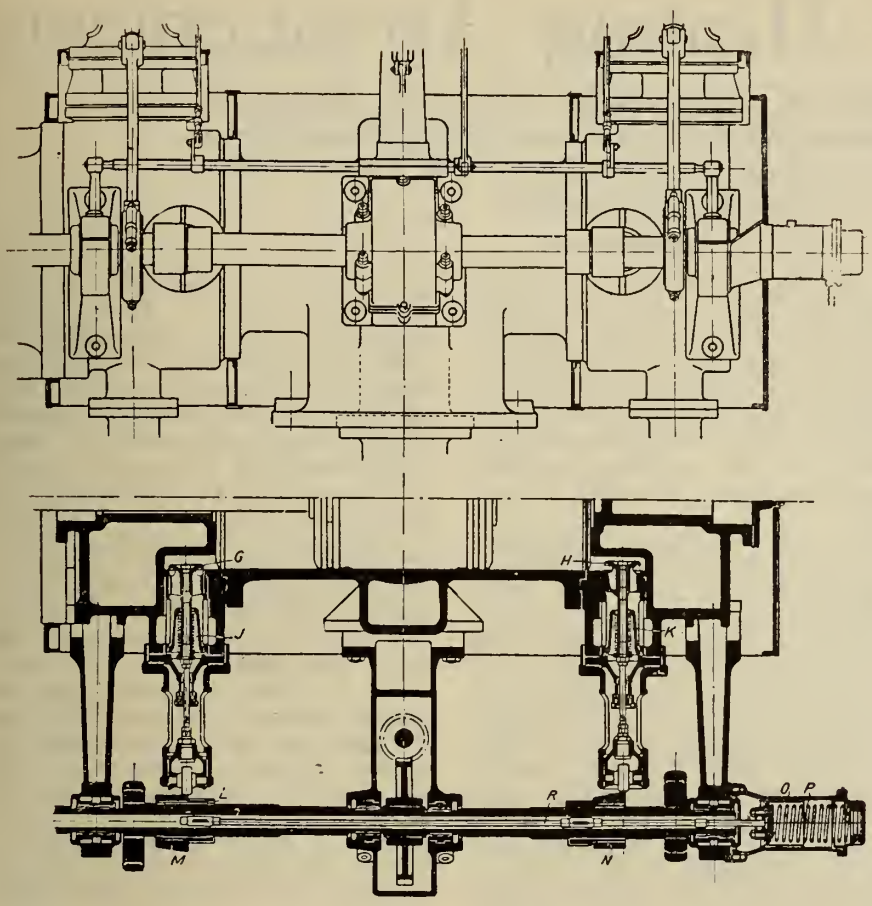

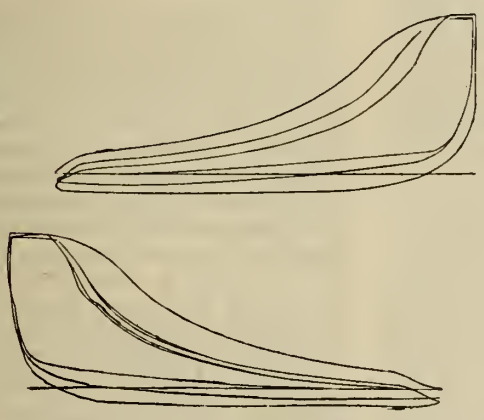

Fig. 3.—Arrangement of the automatic exhaust gear. Fig. 4.—Indicator cards.

Heenan and Froude dynamometer. As no surface condenser was fitted at the time the steam consumption was measured by observation of the boiler feed. The boiler being the same that was used for the heating system of the works with heating pipes blanked off, neither the specified boiler pressure nor superheat was available. The piping arrangements were also temperary, the stop valve being about 20ft. from the cylinder. The pressure and superheat at the stop valve were 125 lb. per square inch and 50 deg. Fah. respectively, and in spite of these adverse conditions the results of the tests, after making the necessary allowances for the change of pressure and superheat to the specified valves of 160 lb. per square inch and 120 degrees Fahrenheit, confirm the figures guaranteed, namely 12.6 lb. of steam per brake horse power hour which must be considered extremely satisfactory for an engine of such a comparatively small size.

PUTTING WASTE VAPOR TO WORK

The method employed to increase the capacity of a heating plant for a paper mill was described recently by W. H. Howell, Jr., before the technical association of the pulp and paper industry. The capacity in this particular case was increased by the proper utilization of waste vapor and Mr. Howell stated the usual practice has been to heat fresh air from outdoors by carrying it over steam coils, blowing it into the room and taking out the moisture from the driers either by having openings in the roof or with exhaust fans. This system has been quite highly developed and gives satisfaction provided it is properly installed.

At the mill referred to, this old system was in use, but as the production was increased 100 per cent. it was found to be inadequate. It was then arranged to ventilate the machine room with two fans. One exhaust fan is used for pulling moist air out of the machine hood to the economizer and a supply fan distributes the warm air and the fresh cold air crisscross each other in the economizer without actual contact except through corrugated plates. The object of the corrugated plates is to enable the closest possible contact for transmission of heat from hot moist air to the cold fresh air, at the same time separating the moist air from the dry air. Both fans are belt-connected to a single 20-horsepower constant-speed electric motor.

In average winter weather (34° Fahr.) the economizer is able to raise the outdoor air to 107° Fahr. for distribution in the machine room in quantity sufficient for all ventilating purposes and without the use of any steam whatsoever. This result is accomplished solely by utilizing the waste vapor going out of the machine hood and still leaving a large quantity of vapor available for other heating purposes.

It was found that 107° was too warm for the comfort of the operators, and a certain amount of moist air was consequently allowed to escape into the atmosphere without passing through the economizer, so as to bring the air temperature supplied to the room down to 98° or 100°.

Mr. Howell stated that, so far as he knows, this is the first practical use of the idea on a large scale for heating and ventilating a machine room without the use of steam from the boiler plant. By its means first-class ventilation conditions are assured in a place that formerly presented a very difficult and expensive operating condition. Of course the intention is also to use such waste heat in some cases to assist drying operation in the summer.

BULLETIN

The Bailey Meter Company have issued Bulletin No. 6 describing briefly a number of their different types of meters for various services. An illustration of a minature gas fired boiler, built to one eight scale of a 1024 h.p. cross drum water tube boiler, with glass drum heads and one side of the setting made of glass is on the front page. This is used in conjunction with a type D 25, Class 56, meter, which records Steam Blow, Air Flow, and Gas Temperature, and indicates Fire Box draft. Bulletin 42 contains complete description of the Bailey Boiler Meter.

Back Pressure Heating Arrangements

The Following Remarks Contained in the Chief Engineer's Report to the Manchester Steam Users' Association, Should Help to Make This Interesting Subject More Clear—The Thermal Side is Treated Very Lucidly

By C. E. STROMEYER

ALTHOUGH the principles on which heating by means of exhaust steam from engines is based are well understood, it seems advisable, on account of the somewhat complex nature of the subject, to restate these with the help of a few simple diagrams.

The heat equivalent of one horse power per hour (550 foot pounds per second) is 2,540 British thermal units. It can be represented by the heat contained in 2 pounds of high-pressure superheated steam, or by the heat of combustion of 0.2 pounds of ordinary coal of, say, 12,700 B.T.U.'s.

It is very desirable throughout the following considerations to disabuse our minds of the notion that ten, twenty, or more pounds of steam per hour are one horse power. Steam is merely the conveyor of power, as copper wire is the conveyor of electricty. This conveying power is limited. For instance, a copper wire would fuse if too much electricity were passed through it, and in practice a limited quantity, say, one and two thousand amperes per square inch, are found practicable. Similarly with regard to steam and power. One horse power is represented by the evaporation or condensation of about two pounds of water or steam per hour, but in practice more than ten and sometime up to fifty pounds of steam have to pass through an engine to produce one horse power. The heat contained in this large quantity of steam is wasted, all except that represented by 2-1 pounds of high pressure steam. It is either blown into the atmosphere or into the condenser. Back-pressure systems aim at utilising this enormous waste for heating purposes. A customary condensing engine of, say, 100 h.p. will have a steeam consumption of say 1.4 lbs. per I. H.P. per hour. The heat supply to the boiler will be equivalent to 1500 lbs. high pressure steam. The chimney losses and radiation are equal to 450 lbs., leaving 1050 lbs. to be supplied to the engine. The engine uses only 210 lbs. of this, 840 lbs. being rejected to the condenser. This 210 lbs. is equal to 100 H.P.

A non-condensing high-pressure engine would have a heat supply to the boiler equal to 10570 lbs. The radiation and chimney loss will be 3170 lbs. The steam supply available for the engine will be 7400 lb. and using the same amount of steam in the cylinder to produce 100 H.P. and exhausting against 60 lbs. absolute back pressure, 7190 lbs. steam are available for further use.

If instead of 60 pounds absolute back pressure, as assumed in the second case 30 pounds absolute or 15 pounds above atmosphere were to be adopted, the weight of exhaust steam per hundred h.p. would be about 5,300 pounds instead of 7,190, the steam supply to the engine 5,510 pounds, the chimney waste 2,360 pounds, and the heat supply to the boiler would be equivalent to 7,870 pounds steam, say, 730 pounds ordinary coal.

In the non-condensing engine there would be available for heating purposes at 45 pounds pressure, or 292° Fahr., about 7,190 pounds of steam per hour, capable of heating about 3,600 gallons of water per hour to boiling point. In the second case the available pressure would be 15 pounds, with a temperature of 250° Fahr., and its heating capabilities would be 2,650 gallons per hour. In both cases the 100 horse power would cost practically nothing, viz. 210 pounds of steam, or 20 pounds of ordinary coal. In other words, when all the steam can be utilized for heating or other purposes the power derived from it costs nothing. It is obviously, therefore, highly enconomical for those works which use much steam for heating, to produce power with it and use or sell it; and those works which produce much power might sell their waste steam for heating purposes.

Those cases in which the heating requirements are greater than can be obtained from the engine exhaust, although relatively few in number, are of great importance, and as is these works there is much scope for electric heating, it is desirable to consider whether some of the exhaust steam could not be converted into electricity. Assume that one of these works requires an effective back pressure of 15 pounds and 5,300 gallons of boiling water per hour. Two engines of 100 h.p. each could be run in these works, the one driving the machinery either direct or by means of electricity and the other producing electricty for heating purposes, equal to an additional 105 gallons of boiling water. Heating by electricty, especially when it costs practically nothing, has many advantages. High pressure steam vessels in the midst of factory hands could be dispensed with, and any desired temperature could be attained without having to contaminate the air with burnt gas. Therefore, in all those works where direct heating is done by low pressure boilers there is a probability that much heating might be done by electricty without extra cost.

The majority of works require less heat than that which is at present discharged by their driving engines assume a case where the available back pressure has to be 15 pounds, then if the heating requiremests are 4,500 pounds steam, or, say, 2,250 gallons of water, it would, from an economic point of view, make no difference whether these 4,500 pounds of steam were drawn direct from the boiler, costing the equivalent of 6,370 pounds of steam plus 1,500 pounds for producing 100 horse power (total 7,870 pounds), or whether the exhaust steam from the engine were used, which, as shows above, amounts to 7,870 pounds. In this case, of course, the difference between 5,300 and 4,500=800 pounds of steam would be blown to waste, and the thought naturally presents itself that this portion of the steam should not enter into the back pressure main at all, and, therefore, not through the non-condensing engine but should be passed through a highly efficient condensing engine. This is essentially the principle on which extraction engines are designed.

Before deciding whether a back-pressure system of heating is to be adopted it is essential to know the steaming and heating requirements of a factory. If they exceed say 20 to 25 gallons of boiling water per hour one horse power, then a back-pressure engine should be advantageous; if the requirements are less, then an extraction engine, or live steam heating combined with a very efficient engine is more economical, but the engine has to be very economical, In practice the fuel expenditure is more often above 2.8 pounds of coal per one h.p., than 1.4 pounds as here assumed, whereby the relations are materially modified. The limit between the use of live steam and back-pressure steam would, therefore, in practice, be reached when the heating requirements are about 15 to 20 gallons per hour per indicated horse power. Of course, wherever non-condensing engines are used, it is certainly advantageous to employ the exhaust steam for heating purposes.

The difficulty of deciding on the best plan to be adopted is due very generally to ignorance as to the relative steam consumption in engines and heating appliances, but the ever-increasing accuracy of steam meters should make it possible nowadays not only to measure steam consumptions for reorganisation purposes, but also subsequently to check the waste of individual steam consumption appliances.

Manufacturers who may wish to utilise their back pressure for heating purposes will have to consider the question of adapting their engine to this pur-

pose or whether it would be advisable to replace it by a back-pressure turbine. A rough but reasonably accurate rule is that a condensing engine making 60 revolutions per minute develops from 8 to 10 horse power per cubic foot, plus 25 per cent. for the high pressure cylinder in cases of compound engines. This estimate applies to engines in which the absolute back pressure is about one-third of the absolute boiler pressure. It has to be reduced by about 25 per cent. if the back pressure is one-half of the boiler pressure.

There is, therefore, no difficulty as regards size of engine in changing from the condensing principle to the back-pressure principle, but most low-pressure cylinders are very weak and would have to be replaced by stronger ones of the same or smaller dimensions. When such a change is under consideration the advantage of using a back-pressure turbine should not be overlooked. That advantage is that the exhaust steam is not contaminated with grease and can be blown direct into the water to be heated, without the intervention of heaters and coils of pipes.

The cylinders of a simple high-pressure condensing engine will always be both large enough and strong enough for conversion into a back-pressure engine.

In some works much power and steam are required during the day, and little power, but the same quantity of steam, at night. These cases could usually be met by lowering the pressure during the night and using steam direct from the boilers. The reverse conditions —power night and day and steam for heating during the day—could be met by bifurcating the exhaust, and fitting two large valves, the one opening to the condenser the other to the back-pressure system. With compound engines the arrangement is more complicated.

Many recommendations have been made to abstract steam for heating purposes from the engine at some convenient intermediate pressure. Theoretically, as already pointed out, a saving can be effected by this means, but unless the demand for steam for heating is steady this system introduces fluctuations into the engine speed which cannot well be met, except by the use of two governors. The nature of this difficulty will be apparent by once more glancing at the back-pressure engine. Assume that a back-pressure engine is being supplied with steam of 150 pounds absolute and exhausting against a pressure of 60 pounds absolute, then if the demand for power be increased, the governor would increase the steam supply by shifting the cut-off. But this increase would also increase the back-pressure and, under certain relations of pressures, the result would be a reduction of power. Then also if there should be a sudden heavy demand on the back-pressure steam, the power would naturally increase above requirements and the governor would reduce the steam supply and cause the back pressure to sink still further. This difficulty can be met, within limits, by throttling the exhaust, but in a paradoxical way, the exhaust throttle valve having to be closed more and more as the back-pressure sinks. The first effect would be to reduce the power, but then, of course, the inlet governor would admit an extra quantity of steam as required. In other words, the greater the demand for back-pressure steam, the horse power remaining constant, the more inefficient will the engine have to be made, and the simplest plan for doing this is to rise the back pressure. The several pressures can, of course, be regulated by the cut-off and exhaust, or, rather, compression arrangements.

Supplementary means of maintaining a reasonably contant back-pressure is to instal throughout the works in convenient situations large thick-walled vats or metal reservoirs for storing hot water. Here also two regulators would be necessary, one for shutting off the cold water supply whenever the temperature of the contents approached 212° Fahr., and one for increasing the steam supply with increasing back-pressure. If ordinary greasy engine exhaust be used the reservoir water will have to be heated by means of steam pipes and then provision must certainly be made for thoroughly scraping all steam grease out of the pipes. If the back-pressure turbines are used the steam can be blown direct into the reservoir waters.

In very many works reservoirs of boiling water would effect a great saving of time, would obviate inconveniences, and in chalky districts the heating of the water would precipitate most of the lime salts. With a 6 or 9-in. non-conducting covering for these tanks their loss of heat should not exceed about 0.05 pounds of steam condensed per sqr. foot per. hour. A cylinder vessel 6 feet diameter and 10 feet high, holding about 16 tons of water should therefore not lose more heat than is represented by the condensation of 12 pounds of steam per hour, corresponding to a reduction of temperature of this vessel when full, of about 3° Fahr. per hour. A 16 hours, overnight period would result in a reduction of less than 50° Fahr. and 180 pounds of steam blown into the reservoir or into its heating pipes would re-establish a temperature of 212° Fah.

ANNOUNCEMENT

The Canadian agency for the firm of Escher Wyss & Co. of Switzerland makers of turbines, both steam and water, has been awarded to the General Supply Co., of Canada Ltd., of Ottawa.

We have received from Cowlishaw Walker & Co. (1920) Ltd., of 14 Cockspur Street, London S.W.I. their catalogue on "Output" Bar Coal Cutters. This catalogue is very well illustrated, and is of interest to those engaged in the task of winning coal.

JAMES MORRISON BRASS MFG. CO.

In the advertisement of the James Morrison Brass Mfg. Co., Limited, appearing in our issue of August 20th, the illustration of the Pressure Gauge Tester was omitted owing to printer's error. On page 15 of this issue this advertisement is repeated showing the illustration.

DIAMOND SPECIALTY CO. NOTICE

In the advertisement for the Diamond Specialty Co. appearing in our issue of September 5th, in many of the copies issued the address "Windsor, Ont.," did not appear, being broken off early in the press run. The name and address in full is: Diamond Specialty Company, Windsor, Ontario.

BOILER TUBE CLEANERS

Editor, Power House.

Will you allow me to make a suggestion regarding a phase of the article first delivered before the engineering section of the National Safety Council at Philadelphia, and re-published in your publication in the issue of July 20?

The author states that, "Rotary Tube Cleaners, motor or turbine driven, are the only mechanical means for cleaning the interior of tubes of water tube boilers. With curved tubes, the cleaner, in its effort to follow a straight line thru the curved tubes, more or less rapidly wear away the metal of the tube at certain points near the bends and not infrequently the tubes are so thinned by the cleaner that they burst during operation."

There is a method which cleans water tube boilers more thoroughly than cleaners of the grinding type can possibly clean them, and has a decided advantage when cleaning the bends of curved tubes. I refer to the vibratory method. This has long been known to be the logical method for cleaning return tubular boilers, but a great many are not aware that it is equally effective in water tube boilers. Vibration absolutely separates scale from metal, and furthermore, in curved tubes, the oscillating pendulum of the cleaner reaches and cleans every inch of the bends of curved tubes, regardless of shortness of the curves, and without the possibility of grinding away any of the metal tube.

Yours truly,
Geo. Farrow

The Sarco Company Inc., New York City, are issuing a bulletin descriptive of their new type E radiator trap, for vacuum, vapor, and low pressure heating systems. The trap operates with a corrugated tube filled with volatile liquid, on the same principle as the traps made by this company for so long. The body of the trap is of heavy cast brass, and the whole construction is rugged and well suited for the purpose it is made for.

Overhauling and Adjusting in the Engine Room

In This Article We Have Gone Into the Question of Systematizing the Ordinary Works of the Engine Room, and Show Some Methods of Keeping Records and Standard Information

By "FITTER"

A NUMBER of different styles of pumps have been discussed, sufficient we think, to make the general principle on which they are designed familiar to those who are interested in these articles. A little has been said in regard to their maintenance and repair, and before we proceed to other engine room apparatus, some few hints will be given on systematising the work of overhauling. By the taking of a little preliminary trouble, much time and material can be saved, to the mutual advantage of the engineer and his employer.

We have spoken before of the lockers or cupboards found in some plants, which contain all kinds of packing, in odd lengths, unsuitable sizes and short ends no use for anything. These all represent money wasted, and also time wasted which might have been spent in recreation to much better purpose. A cupboard such as this represents culpable carelessness, perhaps not on the part of the man actually in charge at the moment, but on his predecessors. These long and short lengths of various brands of packings sometimes represent the art of some supply salesman, who has persuaded the engineer to try his goods, and has sold him a great deal more than was necessary for a trial, with the result that the majority of it is wasted. If you want to try a new packing, get just enough to pack one stuffing box once, and if it is properly paced that's all you need for a trial. If the salesman won't supply any less than enough for two or three fillings, stick to what you have. We believe that nowadays the engineering supply salesman in general is more conscientious than he once was, and will not try to take advantage of a man who is an easy buyer but there were a large number of salesmen who got themselves and their employers a bad reputation in the past, through these methods.

The Right Way

In the small plant there are not many rods and glands to pack, but still there are sufficient to make a good deal of waste possible if care is not exercised. If the man learns to be careful and systematic in the operation of his first small plant, he will not forget these characteristics when he achieves the largest plant and greater responsibility, and he will have cause to bless his early training.

Let us take a typical small plant containing a Corliss engine, a boiler feed pump, a general service pump, and an Underwriter type fire pump. There are a great number of plants of just about this type. Now let us see what we have in the way of packing in these units. Take the main engine first. There are the piston rod stuffing box, and four valve spindle stuffing boxes. Suppose that the boiler feed pump is of the outside packed duplex type. On this pump we shall have four glands on the plungers, two glands on the piston rods, and two glands on the valve spindles. The general service pump will be of the piston type inside packed. We will have then the piston packing, the two stuffing boxes on steam and water ends, and the valve spindle gland, and if the pump is a duplex we can multiply these by two. The underwriter fire pump will have two packed water pistons, two water and two steam rods to be packed, and two valve spindles to be packed. Without considering any small glands for the moment let us see what we have on these pumps and engine alone.

Allowing the general service pump to be a duplex, here we have in the small plant no less than 29 places that have to be packed. In these 29 places, there are 13 different sizes of packing required, and there will be two different types, one being for water, and one for steam.

Ring or Coil

Now it will be best to decide whether we wish to use packing cut to the size of the rod in ring form, or buy it in spiral coils, by the box. In either case we pay for the actual weight of packing we buy, but buying it in rings, we pay a little more, to cover the factory cost of making the rings. For rods under two inches diameter, there is no doubt that the ring form is the more economical. It is easier to handle as it can be slipped

Log sheet for small plant.

round the rod, and pressed into the stuffing box with a great deal of ease. Then again, where the width of the stuffing box is large in comparison to its diameter, it is a difficult matter to bend the packing round the rod if in coil form, and cut it to the right length without considerable waste. On small rods such as valve spindles, the ring form cannot be beaten. When we come to the large rods such as the piston rod of the main engine, it becomes a matter of choice but even here we give the preference to the ring form. Large size packing in the spiral form comes in boxes as a rule, and there is always a certain amount of waste. If packing can be obtained in lengths that will cut up evenly, without leaving half or three quarters of a turn to be thrown away, it is perhaps better to buy it in that form.

We may say that in this particular case, ring packing will be bought for the small rods, that is the steam rods, and coil packing for the main piston rod. Then comes the question of water ends and pistons. Here the engineer will have to use his judgement again. For the plungers of the outside packed feed pump he will require a packing that will stand hot water, will possess lubricating qualities, and at the same time have good physical strength to uphold the weight and friction of the plungers. It is not our intention to bring down the wrath of rival packing manufacturers on our heads by picking out one or other brand, but just to mention what characteristics are required to obtain satisfaction. There are any number of packings on the market which come up to this specification and it is for the individual engineer to find the one that gives him the best wear without injury to rods, and a minimum amount of loss by leakage. These things are more than first cost, and in considering packings any other material, do not be influenced by price alone. As a matter of fact there is little difference between standard packings in the matter of price.

For the packing of water pistons a packing that will not absorb much moisture, and possesses a good deal of flexibility, with strength is what is required. That means any good fibre packing. The actual wear on this packing due to the weight and friction of the piston is not as much as on the packing in the outside packed pump, owing to the greater area it is distributed over. We have now got three types of packing, to be bought in the various sizes required.

Now a man may order packings himself direct from the agent or salesman, but very likely he will have to make a requisition to the office, and the purchasing agent will do the buying. If our engineer doesn't know very definitely what he wants, this allows some latitude for the purchasing agent to try his hand, with generally evil results. Therefore, know just what you want and why you want it, and be able to state clearly the reasons.

It is necessary in order to know what size packing to order, and when to order it, to have a record of all different sizes of packing that are in use, and there are right and wrong ways of keeping a record of these sizes. Some men have them chalked on the wall, while others keep them in a pocket book which usually can be understood by the man who owns it and no one else. When he goes to another plant, the next man has to make all the measurements all over again. The best way is to make a blue print, or rather make a tracing from which any number of blue prints can be taken, and then order the packing from the blue print. The illustration shows the method of doing this, and we know of no more satisfactory way. That is all right so far as the ordering for sizes goes. There must be a method of stock keeping, and something in which to keep tabs of the way the material is standing up. In other words, a record must be kept of the amount of packing, valves, etc., used by each unit, and the length of time between each repacking or renewing of valves or any other repair that may be made. These should be shown on the weekly log sheet and also transferred to a book or looseleaf system in which each unit is shown separately. This may seem like a lot of work, but in reality the whole thing doesn't amount to five minutes work a week, and the record is well worth while. Suppose you have a pump which is giving a lot of trouble, and you want to have it thoroughly repaired, or better still, replaced by a more economical unit. If you have kept a record of time and material spent in repairing that unit, which record should also contain the actual time it is out of operation, you have got a very good argument to put up to the management. Of course in large plants, these things are compulsory, but there is no reason why they shouldn't be done in the small plant. When the engineer of any plant, however small, can go to his employer and show him in black and white where the money is being spent or saved, the employer is going to look on that man as something more than a laborer, and is going to be more willing to discuss necessary improvements and instruments in the power house.

When you have a record of just when a rod was packed, and how long it usually runs between packing, you don't have to wait till the gland starts blowing badly and perhaps have to shut down to pack it. Your record will show you when to take an opportunity to repack the pump, and if the outside rings are good when you take them out, you may use them again putting the new rings in the bottom of the box, and making a note of just how much new and how much old there is in the stuffing box. If you don't care about using any packing over again, let the rod run till it shows unmistaable signs of needing attention, and then repack it completely. Your work will be lightened, and the upkeep of the plant will be less, and rods

in better condition if packing is renewed under a definite system. If certain rods require renewing more often than others ascertain the cause, because rods in the same kind of service if in good condition, should run the same length of time. Glands which are not difficult to keep tight, are often through that reason neglected, and it is only when too late that damage is discovered. The valve spindles of Corliss engines, especially on the exhaust side, are very often scored and worn oval simply because they haven't leaked, and the packing has been allowed to get hard, and injure the spindle. Valve spindles on steam pumps are very often left to run with packing that has become hard and because they do not leak very much, are not bothered with. The result is badly worn spindles. The spindle is worn out for the sake of a bit of time and trouble in packing, and a good deal more time and expense is necessary in order to renew the spindle. Hard packing in the water end of a pump rod is a frequent source of scored rods, and these glands should be well looked after. A leak all round one of these glands is much better for the rod than a leak in one spot. A small stream of water continually spurting from one spot in a gland will soon make a deep score in a rod, and especially in a brass rod. A gland evenly packed, and not too tight, with packing renewed before it gets hard, is the best safeguard against scored rods. When a rod does get scored it should be turned up immediately, as it is only waste of packing and time to try and run a badly scored rod.

Keeping Tabs on Valves

The various valves needed on the different pumps should also be carefully tabulated for size, and the length of time that they last. The springs and studs should also be recorded so that they can be ordered when necessary without taking off the cover of the pump to get a sample. When going into a plant where this has not been done previously, opportunity should be taken whenever a pump is opened up to get a sketch of the valves and studs. If there is a drafting office in the plant, get the draughtsman to make a proper dimensioned drawing from which a tracing and eventually blue prints can be made. The tracing is then kept on file and blue prints made when necessary. If there is no drawing office, make a tracing yourself, from which you can get blue prints made with the expenditure of a few cents. No plant is too small to have these blue prints, and the little bit of trouble involved is amply repaid by the saving in time and accuracy obtained.

The accompanying illustrations show the kind of records that may be made and of course they can be adapted to the needs of individual plants.

SELECTING PROPER LUBRICANT

"In deciding upon the proper lubricant many factors enter in of which the average engineer has but very meagre knowledge. Oil for one purpose must have certain qualities and must undergo a certain test. This same test for an oil of different character may be absolutely useless as far as proving anything goes. It does, then, become especially desirous to arrive at some standard way of testing oil.

"The governing feature in choosing the proper lubricant," continues W. J. Bitterlich in a recent issue of Factory, "is its film-forming properties under different load conditions. In general, the lighter the oil that forms the proper film for the load pressure, the lower the friction will be.

"The simplest test of all is with the thermometer. The higher temperature of the oil in bearing shows the greater friction loss. This, of course, necessitates experimenting with at least 1,000 or more different oils in every bearing in the plant, which is rather out of the question for many concerns. However, in this particular plant, where the oil bill amounts to $10,000 or more a year, this method shows substantial saving in power consumption and maintenance.

"The question of light and heavy oils may be settled by noting the amount of waste through stuffing boxes and felt washers. Too light an oil will leak excessively. If an oil is exceedingly heavy, however, too much power will be required to start the machinery when the oil is cold."

These two simple tests will prove good guides for the layman in the selecting of proper oils.

EDUCATIONAL

The classes in Power Plant Engineering at the Central Technical School for the session 1921-1922 will be started on October 1. Registration is now open. This year an initial fee of $3 will be charged, and of this $2 will be returned to those students making the required number of attendances. The first year class will be under the instruction of Mr. M. B. Watson, Director of Engineering, Central Technical School, and the second year class under Mr. T. H. Fenner, Editor of Power House.

The classes will specialize on the necessary work for the Ontario certificates, paying special attention to fundamental principles, and engineers in the city are strongly advised to avail themselves of the opportunity these classes afford.

LOSS OF HEAT FROM BARE STEAM PIPES

FOR bare steam pipes this loss may be taken as 2.7 B. t. u. per hour per square foot of surface per degree Fahrenheit difference between the temperatures of the steam and the outside air. Thus, if the pressure of the steam is 120 pounds absolute, the corresponding temperature being 341°, and the temperature of the air 60°, then the loss per hour per foot length from a 4-in. steam pipe, the external surface of which is 1.178 square feet per foot of length, will be $1.178 \times (341-60) \times 2.7 = 894$ B. t. u. The corresponding condensation can be found by dividing this heat quantity by the latent heat of steam at the given pressure. In the example given above, the latent heat of steam at 120 pounds pressure, absolute, is 877.2 B. t. u. Therefore the condensation per hour per foot length of pipe is $894 \div 877.2 = 1.02$ pounds. — National Tube Co.

PREVENTING AMMMONIA LEAKAGE

The advantage of permanence, lower cost, and ammonia saving, gained by eliminating joints in ammonia pipe coils by Thermit welding as compared with installing ammonia flanged connections is being appreciated according to reports by the Linde Canadian Refrigeration Company, Montreal, Que., which handles refrigeration machinery for industrial plants and ships.

Since adopting this pipe welding process in 1918, the company has ordered material for welding in the neighborhood of fifteen miles of 1¼ inch extra heavy steel and wrought iron pipe for refrigeration units installed in a large number of industrial plants. The length of coil used varies from 500 to 5,000 feet. The whole coil is made up in sections of endless pipe. These sections are flanged and bolted together on the job. The sizes of the sections vary from 6 feet to 36 feet in length, and from 3 pipes high to 20 pipes high. There is one weld for every 20 feet of pipe used. No screwed fittings are used on any of these installations, but instead the pipe is bent to suit, and male and female flanges are connected together using a lead gasket. The coils are flanged before being shipped and tested to at least 150 pounds hydrostatic pressure test. In very few cases has it been found necessary to cut out a weld.

NEW PAPER MACHINES

The Laurentide Co., at Grand Mere, Que., have recently installed two new 166-in. news machines. This means that they will be able to produce marketable paper at the rate of at least 1,000 feet per minute. The machines have a daily capacity of 75 tons each, and were made in Canada. The Dominion Bridge Co., built these machines.

Steam pressures have advanced very rapidly, and in this direction Britain is ahead of America. Two hundred and fifty pounds is quite common, several boilers are working at 350 lb., and in one case at 475 lb. pressure. Evidence so far collected is that maintenance is not greater on boilers working at 350 lb. pressure than those operating at lower values. Safety, with first-class construction, is not a matter of pressure, and an explosion on a plant working at 500 lb. would be little more disastrous than on one operating at 100 lb. Taking into account the present factors of safety, states a well-known authority, conditions are safer in the former case.

WAS THIS A COLLAPSE?

The Editor,
POWER HOUSE
Dear Sir,—

I was much interested in the article entitled "What Pulled the Head In." As a brain exercise it will be alright to attempt a reasoned explanation of the failure without further knowledge and personal inspection, but I doubt if it will end in a satisfactory solution. The front tube plate has very little support against collapse inwardly. It is true that the stay tubes are screwed into the plate and that the long stays may have a nut and washer inside but the plain tubes are only expanded. The expander leaves a taper small and inwards and only initial friction to motion is left. This in an overheated plate might disappear. We cannot therefore consider all the tubes as setting together as one column with a large radius of gyration. If we take each stay tube and stay as a separate column, are they of much use in this way? I don't think so. They can hardly support themselves and unless in tension will have an initial sag in the horizontal position. The flanged edge would become a source of weakness while it was being bent outwards or downwards by the bu'ging shell plate as shown in the photograph, just as the centre of a round lid such as that of a spice tin would be driven upwards if you attempted to flatten out the edge.

Leaving out heavy sediment and only considering water shortage as the cause of overheating it is reasonable to suppose that the end plate near the brick work also became overheated. The proximity of the brickwork would also tend to keep this part of the end plate in an overheated state longer than the bulged shell plate. Now are we sure that at this stage of the game there was not a partial vacuum formed in this boiler due to the rapid cooling of one kind and another? We would then have an overheated end plate, poorly supported against external pressure with an initial strain and even deformation due to the flanged edge locally following the line of the bulge in the she'l plate and subjected to an external stress greater than internal. It may be that the local flattening of the flanged part did all the damage. Suppose we admit this hypothesis we can still I think claim that external influences caused the collapse using external in its broad sense. The heat was supplied from outside causing the shell plate to bulge downwards thus supplying the force necessary to distort the end plate.

Our correspondent has started the ball rolling, and experiences a wish to hear from others. Our columns are open to all who wish to give an opinion. There is one point on which Mr. McDonald is in error. There are no stay tubes in a horizontal boiler, all the tubes being expanded into the end plate.

THE BEHAVIOUR OF PUMP-VALVES

The results of exhaustive experiments made on six types of valves are summarised in this article, which is abstracted from "Forschungsarbeiten aus dem Gebiete des Ingenieurwesens," No. 233. The author obtained a number of diagrams of the movements of the suction and delivery valves of pumps and of the pressures below the suction valves, in the pump chambers, and above the delivery valves. Particular attention was paid to the intensities of the sounds associated with the opening and closing of the valves. For the suction valves noises occurred on closing, and were soft when the final velocities of the valves were about 3-in. per second, and loud when the velocity exceeded 5-in. per sec. These velocities and the intensities of the blows, increased with increase of spring loads on the valves. The blows of the delivery valves increased with increasing lifts and diminishing spring loads. Rather severe water-hammer blows were delivered against the delivery valves just before they opened. Apparently a vacuum is formed through the closing of the suction valves just before the end of each stroke. These blows on the delivery valves increase in violence with increasing spring loads on the suction valves. Several other details are discussed, including the efficiency of pumps.—L. Krauss ("Ver. deu, Ing.")

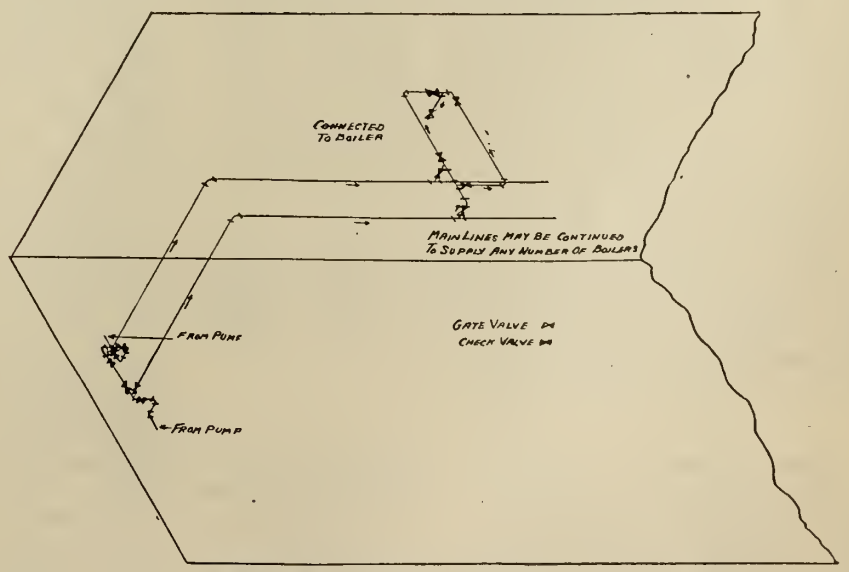
BOILER FEED ARRANGEMENT

By M. C. Allen

Where boilers are operated for twenty-four hours per day and seven days per week, it is necessary when cleaning a boiler to force the others sufficiently to carry the load. In a case like this the feed arrangement should be very carefully planned and laid out so that delays or shut downs shall not occur through inability to supply the boilers with water. These delays may easily arise through faulty valves on the feed line. After experiencing some trouble through causes of the above nature, feed line layout shown in the accompanying sketch was adopted, and the feed water line troubles disappeared.

The system was originally designed to take water from three pumps and so arranged that water could feed from any pump to any boiler and through any part of the line desired. The main lines were carried over the top of the boilers and two branches were connected to each boiler. This gives two check valves for each boiler and allows one to be repaired while the other is in use. Any part of the line may be repaired and the boilers fed through the other line. In the particular installation under consideration a Venturi meter was placed in one pipe line and by this means it was possible to measure the water going into any or all of the boilers and an evaporation test could be made on any boiler at any time desired by feeding that one boiler through the line containing the meter. The valves between the main lines and the various branches were equipped with chain blocks and opened or closed by means of endless chains which came down to within five feet of the boiler room floor. This installation was made on four Stirling boilers and one of the two branches going to the boilers extended about three feet over the side of the boiler to allow a feed water regulator to be installed. After about two years service the line has given no trouble and all repairs or adjustments have been easily made with the boiler under steam. The risers from the pumps were supported on the wall and the horizontal lines were suspended from the roof trusses. There was very little vibration in the line but an air chamber or other cushioning device would probably be found useful to the system.

Catalogue No. 50 just issued by the Julian d'Este Company, Boston, deals with Curtis Engineering Specialties, including pressure regulators, for steam and water, steam traps, damper regulators, relief valves, pump governors and special miscellaneous valves.



Arrangement for boiler feed lines.

Is The Law Enforced?

FROM time to time complaints have been reaching us relative to the enforcement or lack of enforcement of the Stationary Engineer's Act in Ontario. In some cases where the information seemed to be definite we have forwarded the complaint to the Board of Examiners, and have received their assurance that an investigation would be made. While many of the complaints have been of a shadowy nature, such as could hardly be acted upon without more definite information, there would seem to be some grounds for dissatisfaction, even if on the principle that there is no smoke without fire. Recently we have heard some very positive statements from men who claimed they could back their statements up with absolute evidence.

We have always taken the attitude, and it is our firm belief that the Board of Stationary Engineers is actuated by absolutely fair motives, and wish to give to every engineer a square deal. We have had no positive evidence to make us rescind that view, but at the same time cannot shut our ears to the undercurrent of dissatisfaction that prevails among a good many reasonable men in stationary engineering circles. It cannot be denied that if the law is not administered with absolute impartiality, and firmness, a huge injustice will be done to the great majority of stationary engineers. Certain standards have been set by the examining board for the different grades, and these standards should be exacted from every candidate who presents himself, without exceptions or favor. Where a plant is of a nature to demand a certain grade of certificate that grade should be insisted upon, no matter who may be inconvenienced in the process. The law is on the statute books, and we have seen how ruthlessly some laws can be administered in this province. While we believe that laws should be administered with a certain amount of humanity and reason, we do also believe in them being administered absolutely impartially. We believe, as we have often stated, that if any case exists where the law is being disobeyed, that it has only to be brought to the attention of the authorities to be remedied. At the same time we think that these authorities have the necessary machinery to become acquainted with these cases without the duty of informing devolving on private citizens.

If any reader of Power House has knowledge of such a case, and can bring properly authenticated evidence to back up his knowledge, we will gladly undertake the task of bringing it to the attention of the Government. It must be understood that rumors and hearsay are of no use for this purpose, facts being the only thing necessary.

The Stationary Engineer's Education

THERE seems to be a great deal of doubt among stationary engineers themselves as to what they need in the way of education, the younger men generally feeling that they want to get practical knowledge instead of theoretical knowledge. This view also seems to prevail among some of the older men, and even at this late date there seems to be an unaccountable aversion to the acquisition of theoretical knowledge. This is the more unaccountable because in almost any walk of life, men are interested in finding out the why of things. The average man looking at a submarine is not content to know that he can submerge, but wants to know something of the reason that makes her capable of submerging and emerging. The work of the engineer who has a knowledge of the principles governing the machinery he operates becomes of vast interest, instead of a mere drudgery. There is nothing more fascinating than acquiring knowledge and when the acquisition of knowledge is necessary to the success of a man in his chosen profession it should be a labor of love. The argument that what a man wants is practical education does not seem to us to be a reasonable one. A man who is employed in a power plant, no matter how humble his occupation, is receiving the very best of practical education, and if he is not benefitting by it, it is his own fault. The writer received his practical education by serving a five years apprenticeship in the first place, and has been continuing it pretty nearly all his subsequent life. Practical education can only be obtained by practice, and we can see no benefit in explaining to a man on a blackboard the proper method of holding a shovel or an oil can, or how to tighten a nut. However, if you show that some man the manner in which the laws of combustion come into play when he uses his shovel, how the laws of friction are affected when he lubricates a journal, or how the effort he puts on the end of his spanner is translated into torsional stress on the stud, then indeed you are opening up a new world to that man. Now before he is in a position to thoroughly grasp these things, he must have a certain fundamental outfit and the principal part of this is a knowledge of the ordinary rules of arithmetic, including fractions, decimal fractions, involution, evolution, mensuration, and enough elementary algebra to understand and use formulae. There is no need for any man to throw up his hands and say he cannot learn these things. It may be difficult, because it is not easy for a grown man to assimilate knowledge as a child does, but the difficulty can easily be surmounted by a little patience on the part of the teacher. The fact cannot be gotten over, that if a man wants to be a success at any branch of engineering, he has got to master these fundamental ideas, and all the practical knowldge in the world will not get him any where without them. No man should be ashamed of the fact that he lacks this knowledge through unavoidable difficulties in early life. That is a misfortune, but not a disgrace, but when a man has the opportunity to overcome the handicap of early years, and deliberately shuts his eyes to it, then he has cause to blame himself. The requirements of the Board of Examiners for a candidate for second or first class as published elsewhere in this issue state very clearly how much mathematical knowledge he needs, and we believe that the earlier a man starts acquiring it the better it will be for him. By the time he is ready to sit for second or first class he should have acquired a practical education of fairly large extent, if he has availed himself of his opportunities and kept his eyes open. Don't be among those who having eyes see not.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

PRINCIPLE OF DYNAMO

Question: — Please explain what causes a motor armature to revolve, when current is supplied to it.

Answer:—This is a somewhat large question to answer in a short space, involving as it does the principles of magnetism and induction. Briefly it may be explained thus. An armature in its simplest form is a coil of wire, placed in the aperture between the north and south poles of a magnet. That is, the coil is in the magnetic field formed by the lines of force passing between the poles of the magnet. If now a current is passed through the coil, a small magnetic field will be induced around the coil itself. Now this magnetic flux will be in part opposed to the lines of force due to the magnet, but in part it will be in the same direction. Where the two fluxes are opposed they neutralise each other, but where they are in the same direction they will help each other. Thus in the diagram the lines of force above the wire are opposed to each other, while those below are helping each other. The result is a tendency to move the line upwards through the magnetic field. This would continue until the conductor was forced out of the strong magnetic field into a neutral point where there was little or no flux and it would stop. However, in the case of an armature which is built up of a large number of coils, when one conductor is passing through the neutral portion of the field, or rather the point of no influx, another group of conductors is passing through the field all of them cutting certain lines of force, so that the action is continuous. Referring to the smaller illustrations. Suppose Fig. 2 is an elementary armature of a generator and suppose it to be moving in the direction indicated by the arrow. The left hand turn moving downwards and cutting the magnetic flux will have an electro-motive force induced in it causing current to flow towards the observer and out through the left hand brush. The right hand wire moving upwards at the same instant has an electro-motive induced in it in the opposite direction or away from the observer. Travelling in this direction the electro-motive-force will cause current to flow around the wire at the rear and down the left hand side of the loop to the left hand brush the same as before, the two conductors thus reinforcing each other and if the circuit exterior to the generator be closed causing a flow of current out the left hand brush through the exterior circuit and back through the right hand one. When the wires due to their rotation reach a point at right angles to that shown or when they are in a vertical position no voltage is generated and no current will flow. In this position the brushes are touching both sectors on the commutator if they be wide enough. Immediately after this position is reached the conductor which formerly was on the right hand side and was moving upwards, begins to move downwards on the left hand side and its end connected to the commutator is put into communication with the left hand brush. Since in moving downwards the electro-motive-force generated was towards the observer, as before a continuous flow of current is set up. The brushes by running on the commutator not only form a path for the current to flow to and from the armature but serve also to give a continuous or uni-directional current. If instead of a split commutator two rings had been installed one for each end of the coil, an alternating current would be delivered, for each side of the loop would have a current flowing in it first one way and then the other as it came under the influence of first one pole and then the other.

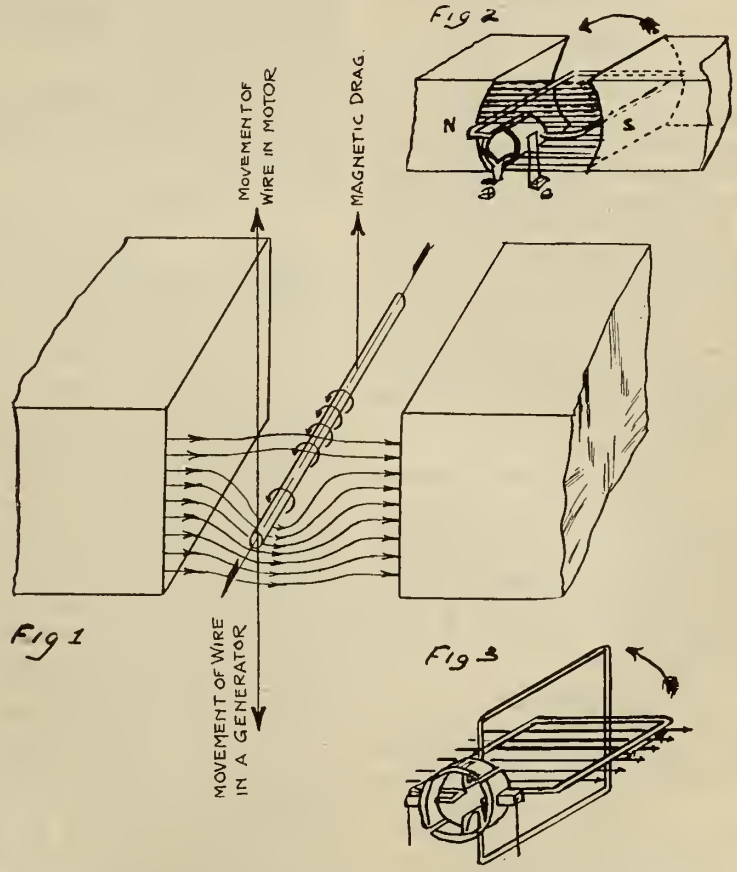

Fig. 1.—Effect of passing current through conductor in magnetic field. Fig. 2.—Single coil elementary dynamo. Fig. 3.—Double coil elementary dynamo.

If two coils of wire similar to the one described be mounted on an axis at right angles to each other with the four terminals of each coil connected to a four part commutator as shown in Fig. 3 then the electro-motive-force generated would be more nearly uniform and in practice commercial machines having a large number of coils, give an almost uniform flow of current, and in the case of motors give an uniform turning moment or torque.

HORSE POWER OF ENGINE

Question:—What is the horse power of an engine and show how to work it out with following particulars? Area of cylinder 341 inches, revolutions per

minute 200, stroke 2 feet, and constant steam on piston 60 lb. per square inch.

Answer:—The horse power is found from the following formula:

$$\frac{P \times L \times A \times N}{33000}$$

where P is mean effective pressure per square inch, L is length of stroke in feet A is area of piston, and N is number of strokes per minute. Substituting figures formula we have

$$\frac{60 \times 2 \times 341 \times 400}{33000} = 496$$

SAVING OF HEAT

QUESTION:—What would be the percentage gained by having a hot water heater with exhaust steam taking the water at 36 degrees Fahrenheit and heating it to 140 degrees F. Show how to find the percentage of gain?

Answer:—The method of finding the percentage of gain in heating feed water is to find the ratio of the heat saved to the total heat in the steam. Supposing the steam is at 150 lbs. pressure per square inch, and a temperature of 366 degrees. Then

$$\frac{T2 - T1}{Ts - T1 \times L} \times 100 = \%\ \text{saving}$$

T2 is the temperature of feed leaving the heater, T1 is the temperature of water entering the heater, and Ts is the temperature of steam in the boiler, L is the latent heat of boiler steam. Substituting figures.

$$\frac{140 - 36}{366 - 36 \times 856.4} \times 100 = 8.7\%$$

Roughly 1 per cent saving of fuel for every 11 degrees water is heated.

AMOUNT OF VACUUM CARRIED

Question:—What is the proper vacuum to carry in a common slide valve engine, cut off at half stroke, and explain why a certain amount is necessary?

Answer:—In ordinary reciprocating engines either simple or compound, though it is usually only in compound engines that condensers are used, the vacuum carried under ordinary circumstances, will be about 25 inches. It is not any advantage to carry any higher than this, and is not practicable. The volume of steam increases rapidly above this amount of vaccum, and it would be necessary to make the low pressure cylinder and its passages very large in order to handle the extra volume, and thus the first cost would be greater than the amount of saving to be gained. If the condenser is of the surface type, and the condensate is used for feed water, a vacuum of 25 inches keeps the water at a suitable temperature, about 125 degrees. Another objection to carrying a high vacuum is the large amount of circulating water needed, which means more work for the circulating pump. In turbine practice it is different, as the gains due to a high vacuum are very large, and the passages ample for the handling of large volumes of steam.

EFFICIENCY OF ENGINE

In the Aug. 20 issue Power House under the above heading, is an answer I do not agree with. In the answer you state that the mechanical efficiency of the engine is probably about 90 per cent. Using the data given and deleting the errors of time, and not stating whether the H.P. given in the question was indicated or otherwise the question becomes:—A steam engine of 120 H.P drives a D.C. generator the capacity of which is 250 amps at 240 Volts. The efficiency of the generator is 88 per cent, what is the efficiency of the engine? My answer is

"The out put of the engine is equal to the brake horse power which is equal to the electrical horse power multiplied by the efficiency or ,

$$\frac{60000 \times .88}{746} = 81.8\ \text{B.H.P.}$$

Output divided by input equals the efficiency of engine. Thus

$$\frac{\times \quad 81.8}{120} = 68\%\ \text{engine efficiency}$$

This engine certainly needs an indicator card taken for valve adjustment etc. Hoping you will show where I am wrong if such is the case. G.A.B.

Our correspondent is in error in so far as he has taken the over all efficiency of engine and generator as the engine efficiency. The efficiency of engine is something entirely distinct from the efficiency of the generator. For instance we might have an engine for the sake of argument which was frictionless, and delivered to the generator shaft the full energy imparted to it by the steam on the piston. In other words we would have an engine of 100 per cent efficiency The generator which this engine is driving might have only 50 per cent efficiency. The efficiency of the whole unit would then be only 50%. Suppose now that our 120 H.P. engine has an efficiency of 90 per cent, (mechanical efficiency). As the generator it is driving is only built to give out 80.40 H.P. the engine would not have to develop anything like 120 H.P. In order to deliver 80.44 H.P. to the generator the engine would have to develop

$$\frac{80.44 \times 100}{90} = 89.37\ \text{H.P.}$$

Now the generator being only 88 per cent efficient, would only deliver at the switchboard $80.44 \times .88 = 70.8$.

Now let us see starting from the engine what we have for over all efficiency

Power put into engine 89.37 H.P.

Power at generator shaft $89.37 \times .9 = 80.4$

Delivered at switchboard $80.4 \times .88 = 70.8$.

Thus we see that the over all efficiency is the efficiency of the engine multiplied by the efficiency of the generator or

$$89.37 \times .9 \times .88. = 70.8$$

To make it absolutely clear if we have an engine of 100 H.P. and a mechanical efficiency of .9 driving a generator with an efficiency of .8 then we get at the switchboard

$$100 \times .9 \times .8 = 72$$

and the over all efficiency is 100×72 or 72 per cent. Thus we see that the engine efficiency has nothing to do with the generator efficiency considered by itself, or vice versa. In the over all efficiency both count.

WORKING OUT CARD

A correspondent sends in a calculation of the indicated horse power of his engine, with a request to correct his calculations where wrong. The particulars he gives are as follows. The engine is a plain slide valve type, cylinder 20 inches diameter and 24 inches stroke, speed 138 revolutions per minute the boiler pressure 95 lbs. per square inch, non-condensing. The result he gets is 498 horse power, and this as he knows is far too high. The error in his calculation consists in having used the boiler pressure instead of the mean effective pressure in making his calculations. The point of cut off is not given, but allowing it to be at half stroke, the mean effective pressure would be approximately 75 lbs. per square inch. The indicated horse power then would be

$$\frac{20 \times 20 \times .7854 \times 75 \times 2 \times 138 \times 2}{33000} = 393.5\ \text{h.p.}$$

If the cut off takes place at 3-8ths stroke instead of half the mean effective pressure then would be approximately, 67 lbs. per sq. in.

$$\frac{20 \times 20 \times .7854 \times 67 \times 2 \times 138 \times 2}{33000} = 347$$

The mean effective pressure is always to be taken when calculating indicated horse power, and is the mean forward pressure minus the mean back pressure on the piston during the stroke.

SAFETY VALVE RING

Question:—Where are the expansion rings in a safety valve and what is their purpose?

Answer:—The ring our correspondent refers to is no doubt the adjustable ring which regulates the opening and closing, or the opening of the safety valve. In order to counteract the effect of the spring compressing, the safety valve is formed with a lip on its edge, which gives it a larger area when open than when closed. On the seat of the valve a ring is screwed, which is capable of being moved up and down. Between the surface of this ring, and the lip of the valve, a chamber is formed known as the huddling chamber. This allows an accumulation of pressure which tends to open the valve further than it would otherwise, and owing to this extra compression the valve closes smartly when the pressure drops. By moving the valve ring up or down, which can be done while the valve is operating, the period of blowing can be made longer or shorter. This ring is found in the type of valve known as pop valves, and is not used in all safe-

Variable Speed Motors in Finishing Plants

The Saving In Fuel Resulting From Their Substitution for Independent Steam Drives, As Shown In The Analysis of the Power Problems of a Typical Finishing Plant

By Warren B. Lewis

THE perfecting of the adjustable-speed, direct-current motor has wrought a revolution in the engineering economics of the cotton-cloth-finishing business far greater than would at first appear to be attributable to any advantage which might be derived from the substitution of electric for mechanical drive. Twenty years ago the stationary, constant-speed electric motor found its application principally in small shops or in departments of larger shops where convenience was the predominating factor. A few years later any proposal to substitute electric drive for mechanical drive met with a demand for proof of greater efficiency in transmission, and several years elapsed before prospective purchasers would admit that the use of electric drives would produce economies outside of the field of simple engineering economics.

The adjustable-speed, direct-current motor opened up a field in which mere mechanical efficiency wos not of prime importance, and established a record for productivity that no other variable-speed device could attain. Since that time the adjustable-speed motor has been considered primarily as a variable-speed device which, by reason of its simplicity, perfection of speed control, etc., has outrun all of its competitors. In this paper it is proposed to show that the usually accredited advantages of the adjustable-speed, direct-current motor are not paramount in its selection for driving certain classes of machinery used in the cotton-cloth-finishing business but that it has made possible a reduction in production costs that are most striking.

Nature of Power Problems in Finishing Plants

In the manufacture of cotton cloth the power problems are of the simplest character. In the finishing business, however, they are most complex. Finishing plants use large quantities of power, heat and water, and so great are these as factors of cost that the very location of a finishing plant is determined by proximity to ponds or streams which will furnish millions of gallons a day of clean water, and adequate facilities for the transportation of fuel, greater in weight than the total weight of the product shipped out.

If one takes occasion to visit the many finishing plants in New England (exclusive of those which have in the last few years rebuilt their power plants in accordance with the most modern ideas—and these are very few in number) he will find a great number of small engines, either belted, geared or otherwise connected to machines which operate throughout a considerable range of speed; and one or more large engines exhausting to the atmosphere or running condensing, driving through the usual line and countershafts machines which operate at constant speed. He will find numerous drying machines using steam at pressures of from 5 to 10 lb., individually driven by the before-mentioned small engines, the exhaust steam from which passes into the machines and furnishes the heat for drying. Small engines driving machines which, in themselves, do not require heat, will probably be exhausting into a main which will be connected also with drying cylinders, furnishing the steam which those cylinders require in excess of that furnished by the engine which drives them. He will notice numerous blower systems furnishing hot air for drying purposes; and in many cases the heating coils of these blower systems will be supplied with live steam. He will notice numerous dye tubs, jigs and vats which are periodically filled and emptied; and which, more often than not, are supplied with cold water which has to be heated to the boiling point with live steam.

If he comments at all upon the use of so many small engines, he is sure to be told that the arrangement is a most economical one, inasmuch as all of the exhaust steam from these engines is used in drying processes, and that nothing is to be gained by substituting some drive which uses less steam per horsepower. Having the engineering mind, however, he will speculate on the heat being discharged from the larger engine, either to the atmosphere or to a condenser, and doubt whether the arrangement is as economical as its owner thinks it is. He will at once realize that the actual brake horsepower required for the entire plant does not balance with the heat being discharged from all of the engines, and that there is very evident room for improvement; and he will arrive at the final conclusion that the small engines are justifiable solely as a means of obtaining varying speeds and not as motive power for producing power as a by-product.

In practically every case a survey of the plant will show that the heat exhausted from the main engines is entirely wasted, except for such as may be used in feedwater heaters. Complete analyses of many of these older plants show that from 3 to 5 lb. of coal are used per pound of cloth finished, which indicates at once the importance of the transportation problem and the extent to which the cost of fuel enters into the total cost of finishing.

As far as electric drives are concerned, the constant-speed machines in a finishing plant may be disposed of briefly, as the problem is very simple and varies only in degree from that which applies to any manufacturing process where the power required to drive the machines should cost a minimum. The same arguments apply, such as lower transmission losses, ability to reduce losses to zero when machines are not in operation, ease of control, cleanliness, etc.

If a perfect balance can be maintained between power requirements and the demands for heat, then there is little more to hope for in that particular direction; or, if in the production of power all of the heat units passing away from the engine can be utilized, then also the desired goal has been reached. Again if all the power required can be produced and the heat discharged from the engine be sufficient for process purposes, then the condition is still better because it is always possible to introduce live steam with the least possible loss between the boiler and the point of use. The adjustable-speed motor has not only made this condition possible, but has actually realized it in plants which have become completely electrified.

Variable Speed Devices

The adjustable-speed motor is an ideal speed-changing mechanism. The degree of variation which may be obtained is greater than in any mechanical device, the ease with which the variation may be obtained is ideally simple, and the efficiency is high. Consider it not as a motor, replacing some other form of motive power, but as a speed-changing device introduced between a relatively efficient prime mover and the machine to be driven. Originally designed primarily for machine-tool operation, it was designated as a constant-horsepower motor, inasmuch as it was generally operated at high torque when running at low speed and at low torque when operating at the higher speeds. As a matter of fact, at the lower speeds its rating was somewhat decreased owing to the poorer cooling effect with low armature speeds, and the greater heating of the fields with full voltage applied to them. A four-to-one motor, rated at 10 h.p. between the speeds of 400 and 1600 r.p.m. would perhaps be better rated at 8 h.p. from 400 to 600 r.p.m., and at 10 h.p. from 600 to 1600 r.p.m. at the same temperature rise.

---

1 Consulting Engineer, Mem. Am. Soc. M.E.; President Providence Engineering Society.

Paper presented at the Spring Meeting of the Textile Division of The American Society of Mechanical Engineers, Providence, R. I., April 12, 1921. Slightly abridged.

As applied to finishing machinery, however, the adjustable-speed motor is more nearly a constant-torque motor. With few exceptions, it is coupled to a machine which requires a fairly definite torque therefore varies with the speed; and if the torque was exactly constant, the horsepower would then vary directly with the speed. This means that the motor operates at its rated horsepower at the highest speed, and at a low horsepower at low speeds. This has both advantages and disadvantages. At the low speed the torque being no greater than at high speed, the reduced armature heating offsets to a certain degree the heating in the fields due to the full field current. On the other hand, at high speeds the armature takes maximum current when the field is weak, which magnifies commutating troubles. The commutating and compensated field motor has practically eliminated this trouble, however, so that these motors will develop full horsepower at the maximum speed continuously and give perfect service.

It has been found that in 90 per cent. of the cases a two-to-one motor will give all of the speed variation that is necessary for general use; while below the normal speed, lower speeds may be obtained for threading up, cleaning, etc., by the use of armature resistance, which by reason of the low horsepower used for so small a proportion of the time, does not affect materially the overall economy of the plant. This makes possible the use of a smaller and more efficient motor for the usual working range.

Note that the losses in an adjustable-speed motor operating under constant-torque conditions decrease nearly proportionately with the horsepower, and then consider this adjustable-speed motor as a device placed between the machine to be driven and the main power unit which will develop a horsepower on about one-third of the steam required by the small engine. Combine the load of all the adjustable-speed motors on to one generating unit, and the result will be a fairly uniform load and practically a uniform steam economy in the prime mover. Compare this with the varying load of the individual small engines in which the heat efficiency is constantly varying, and it requires very little imagination to see where we are being led.

Analysis of a Typical Finishing Plant.

Applying now the general principles set forth in the foregoing to a concrete case, the author will attempt to analyze a finishing plant having a capacity of about three thousand pieces of finished goods per day, two-thirds of which are printed and the other third finished as plain white goods and dyed goods. This is an assumed plant for several reasons; but the principal one is that it is fairly typical from the engineering standpoint.

For the purposes of this paper the equipment of such a plant may be divided into two groups, namely, machines which operate generally at constant speed, and those which operate at varying speeds. The latter being the most important to consider, may be enumerated as follows:

	Max.Hp. of Unit	Max.Hp. of Equip't.
Three singers	6	18
Two mercerizing .. equipments	25	50
Three sets white cans	10	30
Two sets of dyehouse cans	10	20
Six printing machines with their drying cans	30	180
Five complete tentering equipments	12	60
One continuous steamer	20	20
Two aging boxes....	7.5	15
One set starch cans..	15	15
Two open soapers with their drying cans..	30	60
		468

Each of these machines will be driven by variable-speed motive power, i.e., 27 individual steam engines or 27 electric motors, and their total maximum requirements will be, as given in the preceding table, 468 h.p. when operating at their maximum speeds.

Under no circumstances will all of these machines be running at maximum speeds simultaneously, and therefore requiring maximum power. Extensive experience with this class of machinery has proved that the load factor, as it might be termed, is about 50 per cent., and that while any one or even a number of machines may be operating at maximum speeds simultaneously, others will either be operating not at all or at low speeds.

The constant-speed machines in this same plant will require 600 i.hp. if the machines are driven from lineshafts, of which about 50 per cent. will be friction losses. If driven with individual motors, the load will be about 250 kw. This great difference will not be due entirely to the difference between mechanical and electrical losses of transmission, but in great part to the fact that the constant-speed machines will be operated more or less intermittently.

A condition is assumed here which was almost universal up to the advent of the adjustable-speed motor, namely, that the twenty-seven variable-speed machines are driven with twenty-seven small steam engines and the constant-speed machines driven through lineshafting from a simple non-condensing engine. The boiler plant consists of a number of horizontal return tubular boilers, and the average output is 70,000 lb. of steam per hour, about one-third of which is delivered as live steam to processes where high-pressure steam is used.

Condensation in Steam Piping.

There are many hundreds of feet of live and exhaust-steam pipes around this plant, necessitated by the fact that the small engines and process machinery are widely distributed and steam must be delivered to them and exhaust steam taken away from the former. Numerous charts taken from boiler-feed meters will show that the condensation in the steam-piping system will be 10,000 lb. of steam per hour for every hour that steam is on the system, which may and frequently does mean twenty-four hours a day. No material reduction can be made in this loss, except through the removal of all of the piping that is not actually essential to the driving of the machines.

The substitution of the adjustable-speed motor makes it not only possible to eliminate this part of the piping system, but to reduce the sizes of pipes carrying live steam to processes. It is seldom that live steam at a pressure of over 50 lb. is required in the processes; and therefore, with the elimination of the engines, the drop in pressure between the boilers and the processes can be made 50 per cent. or more. Or, still better, the boilers may be divided into two batteries, one group being operated at 150 lb. or more and delivering steam to the main unit and boiler-feed pump, while the other group may be operated at pressures of from 0 lb. down. As a considerable variation of pressure in steam for process purposes is not detrimental, advantage can be taken of the heat stored in the furnaces and in the water within the boilers, so that during periods of heavy drafts the fires will not have to be pushed to maintain steam pressure, while at the slacker periods heat will be stored up.

This has been done in several plants with the result that the evaporation per pound of coal for the group of boilers furnishing live steam for processes has been possible through the introduction of the adjustable-speed motor in place of the small engine.

The heat distribution under the conditions stated may be shown by diagram as in Fig. 1, in which the area of the circle corresponds to a boiler output of 70,000 lb. of steam per hour at 100 lb. gage pressure, feedwater being taken from any source of supply at an average temperature of 100 deg. fahr. and heated to an average temperature of 170 deg. fahr. The question may immediately arise as to why a temperature of 210 or 212 deg. fahr. is not assumed; and the answer is that in practically none of these older finishing plants is the feedwater even heated to a temperature of 170 deg. fahr. This is probably due to the fact that a heater with sufficient surface to raise the temperature of the entire boiler feed from 160 to 210 deg. fahr. would be very large; and with the usual exercise of false economy, heaters of about one-half of the needed capacity are used.

Referring to Fig. 1, the area of the segment A represents the amount of steam which is condensed in the piping system. This figure is taken from actual boiler-feed charts in four plants of approximately the productive capacity of the one that we are considering. The area B is the amount of steam taken by the main engine and is based on 25 lb.

of steam per i.hp.-hr. The area C is the steam delivered to the small engines. The area D is the steam used as live steam in the processes. Segment B is divided to show the amount of heat which is recovered in the feedwater and the heat which is lost. Segment C shows that of 23,000 lb. of steam delivered to the small engines, 20 per cent is entirely lost in condensation, while the remainder may be used for drying purposes.

Steam Requirements for Drying.

The drying operations in this plant will require that each yard of goods be dried three times and will require 1½ lb. of steam per pound of cloth dried. The three thousand pieces will average in weight 10 lb. per piece, and the hourly rate of steam used for drying will be 13,500 lb. From the main engine 10,000 lb. of steam per hour are available, and from the small engine 18,400 lb., a total of 28,400 lb., or more than twice that required. While as a matter of fact it is the exception (rather than the rule) to find a condensing engine doing the constant-speed work, it is apparent that the most economical type of engine would have been the logical thing to have used.

The diagram as presented represents the best condition in that the driers are operating simultaneously with the engines. As a matter of fact, more often than not some of the driers will not be in operation, having completed their day's work before the the end of the working day, or not being in use at all in some of the departments, with the result that the steam exhausted from the small engines will not be reduced in so great a proportion as will the uses of low-pressure steam, and a still greater proportion will be wasted. This is particularly aggravated when the printing department is busy and the dyehouse is not, inasmuch as printing machines always exhaust steam greatly in excess of the requirements in that department.

Segment D of Fig. 1 presents possibilities for some use of low-pressure steam, which, however, were seldom taken advantage of in the older plants, and not always in those which have been rejuvenated. In those processes where it is necessary to heat water up to the boiling point, water may be preheated to a temperature of 160 or 170 deg. fahr. and stored in tanks, from which it may be drawn for use in the dyehouse or in the boiling process. That this has not been done more generally is probably due to the fact that the cost of hot water heating and storage systems is high, and there are difficulties in conveying hot water which are not easily surmounted. It is far better, therefore, to be able to use all of the exhaust steam for direct heating.

This leads up to the general statement that the whole problem of producing power in a finishing plant has been attacked from the wrong end. Analyzed properly, one should first determine the amount of low-pressure steam which can be used economically, and then so design the power plant as to derive all of the power required in the process of producing the low-pressure steam. If it is possible to produce all of the power from the minimum demand of exhaust steam, then the most economical balance will have been attained, because live steam may be introduced through a pressure-reducing valve with practically no loss.

Now for the analysis of this same plant rebuilt in accordance with the statement which has just been made, viz., that the power is to be produced from the steam which can subsequently be passed on to processes with the least loss.

If the plant is to be electrified throughout, the constant-speed motor load will be 250 kw. and the adjustable speed motor load 210 kw. No attempt will be made to discuss the relative merits of a.c. or d.c. generation, this being determined by individual conditions; but for this particular plant it is assumed that a.c. motors are used for the constant-speed work, a motor-generator set to give 230-volt d.c. current for the adjustable-speed work, and a 500-kva. generator which may be either turbine or engine-driven.

The drying operations in this plant require 13,500 lb. of steam per hour at about 5 lb. pressure. The steamer can use 1500 lb. of exhaust steam per hour if it is clean. The two soapers will use 100 gal. of water per minute, which in the old plant has been heated to a temperature of about 170 deg. fahr. by introducing live-steam pipes into the soaper boxes, requiring 5000 lb. of steam per hour. This work can be done with clean exhaust steam, or it can be done in part by collecting all of the condensation from drying cylinders and pumping it into the soaper boxes, instead of back to the boiler-feed heater. This is merely a matter of comparative expense and ease of control.

To heat the feedwater to 210 deg. fahr., 3500 lb. of steam per hour will be required, this figure being derived as follows: The live steam for processes has been reduced from the former requirement of 22,000 lb. to 15,500 lb., requiring that water be taken from an original source and which may be assumed to have an average temperature of 60 deg. fahr. The remainder of the steam (which will be shown later to be 26,000 lb.) will be made from feedwater which has been collected from the various driers at a temperature of 160 deg. fahr., and this being clean water, it can be returned to the boilers.

The total low-pressure steam uses, then, are 23,500 lb. per hour, exclusive of the steam required to heat the buildings, which, taken over a twelve-months' period, may be ignored as far as having any effect upon the design of the power plant.

To operate this plant 460 kw. of electric energy and 23,500 lb. of exhaust steam per hour will be required. A simple, non-condensing, Corliss, releasing-gear engine, direct-connected to a 500-kva. generator will, between the limits of one-half and full load, develop a kilowatt with 42 lb. of steam at 150 lb. initial pressure and 5 lb. back pressure. A 500-kva. steam turbine will operate at the same steam economy.

The turbine has the advantage of giving oil-free exhaust steam. With some precautions the simple non-condensing engine can be used, the chief problem being to remove the oil from the exhaust steam, through the use of properly designed separators. If the plant is already equipped with a good economical reciprocating engine, it would be perfectly good engineering to keep it in service.

To supply 460 kw. at 42 lb. of steam per kw. will require 19,320 lb of steam, and 90 per cent. of this can be delivered to apparatus that can use low-pressure steam at 5 lb. pressure. This will provide slightly less than 17,500 lb. of steam, whereas 23,500 lb. are required. This is a condition which should be very much sought for. If a set of drying cans using a large amount of exhaust steam is stopped for a time, whereas the power required to drive them represents, with the electric drive, comparatively little steam, then there will still be a deficiency

Steam Condensed in Piping System 10000 lbs.
Steam Taken by Main Engine 15000 lbs.
Live Steam Used in Processes 22000 lbs
A
B
C
Steam to Small Engines 23000 lbs.

Diagram showing distribution of steam in Finishing plant.

of exhaust steam in the whole system, and it is always possible to introduce live steam.

The Coal Saving Effected.

In this plant the steam-driven units are confined to one prime mover, and the author would even use a power-driven boiler-feed pump, holding perhaps a steam pump as a reserve unit.

The steam used in this plant, excluding that required for heating buildings, which is a very small amount, totals 43,500 lb.; 23,500 lb. will produce all of the power and low-pressure steam required, 5000 lb. represents condensation, and 15,000 lb. the live steam used direct other than that introduced into the exhaust-steam system. This is a reduction of 26,500 lb. of steam per hour required to operate the plant, and it is easily seen that with an average evaporation of 9 lb. of water per pound of coal over a period of 2700 working hours, this will reduce the coal consumption 4000 tons a year; and this is not the whole of it, by any means.

Finishing plants do not start up at a specified time in the morning and shut

down at a specified time in the afternoon, as do many manufacturing plants. It is the rule rather than the exception that some machines will run overtime, requiring that full steam pressure be maintained on the entire piping system for the benefit perhaps of two or three small engines. It is also the rule rather than the exception that a full steam pressure is maintained on the high-pressure piping-system twenty-four hours a day, with the possible exception of Sundays, entailing excessive condensation losses of more than one-third of the steam which can be accounted for as entering into actual production. With the entire elimination of a large part of the live-pressure steam pipes and a reduction in the sizes of those remaining, not only will the condensation losses be decreased, but it will be possible to shut off the live-steam system entirely when steam at that pressure is not required for high-temperature and boiling operations. Boiling operations carried on at night can be served from a comparatively small live-steam main run directly from the boiler house.

In a certain plant where no printing or dyeing is done, and where the losses through condensation are therefore less than would be found in a plant carrying on all branches of the business, the average boiler load, from 7 o'clock in the morning until 4 o'clock in the afternoon, production being comparatively low, was about 22,000 lb. of steam per hour. For the rest of the twenty-four hours it averaged somewhat more than 8000 lb. per hour. Holiday and Sunday charts in this same plant show about the same amount of water fed to the boilers per hour for the full twenty-four hours. In this case only about one-third of the steam can be accounted for as being directly chargeable to processes.

On another occasion when the plant was somewhat busier, the boiler load was fairly constant at about 30,000 lb. of steam per hour from 7 o'clock in the morning until half past 5 o'clock in the afternoon. From 10 o'clock at night until 6 o'clock in the morning the average rate of feed was 8000 lb. per hour as before.

The maximum boiler load in this particular plant is about 35,000 lb. of steam per hour, so that it is at once apparent that the constant loss of 8000 lb. over twenty-four hour is a very large proportion of the total steam. The remedy for this is to eliminate every foot of pipe which is not absolutely essential and keep steam out of that part of the piping system where it is not needed after the day's work is over.

Influence of Losses on Production Costs

The influence of these constant losses upon the cost of production can be well illustrated by putting production in yards per week against pounds of coal per yard of cloth finished. Such curves make it at once apparent that as the production increases the amount of coal used per yard decreases at a rapid rate, and probably reaches a minimum when the plant is being pushed to its very limit of capacity. The coal in this case represents nearly the entire mechanical costs, exclusive of repairs, viz., power, heat, light, cost of pumping water, drying and boiling operations, and, in fact, everything which ultimately has to be accounted for in the coal pile. While the adjustable-speed motor can hardly be credited with all of the saving which it has been possible to make in finishing plants, its introduction has made the other things simple of accomplishment. Maximum production on any machine must be the offset to rising labor costs. Finishing machines, operated at varying speeds, are subject to many interruptions, and are started and stopped, or slowed down and speeded up, many times a day. With small engines speeds are rather indeterminate. If a set of driers is slowed down and then speeded up again, there is very little assurance that the speed will be brought back to the maximum permissible at the time, because the eye of the operator is the only speedometer available. With the adjustable-speed motor and its predetermined speed push-button controller, the running speed is always returned to one definite speed after a slowdown, and a fair degree of assurance is substituted for guessword.

In some of the processes there are two, and sometimes three, individual machines which have to run in synchronism, the cloth passing through one after the other continuously. With the old mechanical drive the small engine constituted the motive power and the several machines were driven through a series of shafts, bevel gears, pulleys, cone pulleys or Reeves drives, so that the speed could be adjusted to fine limits between the several elements, and then all travel at the same speed.

With the adjustable-speed motor an individual motor can be attached to each element, all operated from one controller, and the speed will be varied uniformly and all elements started and stopped together. This is now the generally accepted method of driving such ranges. If it is desired to operate one element of the range for some particular purpose (as is by no means unusual), then the other motors can be disconnected and the individual machine driven with it own motor.

If the author appears to have been enthusiastic in his presentation of this topic, it is because he has seen the steam consumption of finishing plants reduced to one-half those which previously obtained, and the savings in the cost of fuel pay a very handsome return upon the cost of not only substituting the electric drive but for making all of the other changes in mechanical equipment which could be properly grouped with it.

SAFETY VALVE RINGS

(Continued from Page 32)

ty valves. The amount of extra load due to compression of the spring is in exact ratio to the amount of compression. Thus if a valve is set to blow at 100 lb. per square inch with a spring 6 inches long, and it opens one quarter of an inch the load will be

6 ; 6.25 ; 100 :x 104.16

STEAM PUMP AND FLUE GASES

In the design of a boiler feed pump the ratio of the steam and water cylinders are so arranged that the push on the steam piston is great enough to feed the water into the boiler in a steady stream. The pressure per square inch being the same in the steam and water cylinders. To use steam expansively you would require to increase their ratio so that steam pressure and piston area always dominated water pressure and plunger area. Doing this would not alter (neglecting small losses) the total steam used.

1st case. Steam used at boiler pressure to end of stroke area sq. in. × stroke in. at pressure = Steam used per stroke

2nd. case. Steam cylinder increased to twice the area of 1st case and steam cut off at half stroke.

2 area × stroke at ½ pressure or 2 area × ½ stroke at pressure = same as 1st total.

The speed of your pump would no longer be constant and your pump would cost more. It would also require greater room to house.

As regards second part of this question I do not think there is sufficient information given to discuss same. In a general way if an air leakage increases temperature it would show that there is not sufficient air getting in at the legitimate openings to complete combustion.

TAIL END RODS

The junction of a tail end rod is that of keeping the piston from working on the underside of the cylinder.

To do this successfully for any length of time there has to be added some form of slipper guide and these guides must be kept in perfect alignment with cylinder and crosshead guides.

I have examined a good many old cylinders and have found nothing to encourage the thought that much was gotten in return for the cost of installing the extra guides, rod and gland. There is probably a film of oil and moisture in the bottom of the cylinder sufficient to keep down wear.

The extra gland is a source of waste and the extra floor space often a consideration.

W. B. MACDONALD

We have received from the Dayton Dowd Co., Quincy, Ill., a catalogue describing their centrifugal fire pumps. These pumps are arranged for motor, turbine, or gasoline engine drive. The catalogue is illustrated and shows several views of the pumps themelves and also the plants in which they have been illustrated. Some curves of pump characteristics are also included, and outline diagrams showing space required for installation. The compact arrangement will appeal to factory owners and others to whom space is a consideration.

Combustion and Refrigeration

This Short Paper Given Before the National Association of Refrigerating Engineers, Contains Some Good General Advice on the Subject of Combustion Efficiency

[F given a little latitude we may define combustion as the process of reducing heat. The cycle of events i a refrigerating plant would be interesting, if for no other reason, because in order to get rid of the thing hat we do not want we must first manufacture some more of the very same hing.

There is no special message upon ombustion that can be given to an ssociation of refrigerating engineers. ou want combustion efficiency in your lants for the same reasons that everyody else wants it, viz.: You burn the me kind of fuel that everybody else rns, which may be the fuel best adpted to your furnaces, your boilers, id your load, or it may be whatever el you can get. There are no special signs of boilers and furnaces for refrigerating plants. There are no special lvantages or disadvantages of operaon to be considerated when your plants e compared with those in other lines, less it be the advantage that consists a fairly uniform load and the disadntage that consists of small capacity. he big plant can produce power more eaply than the little one because cost production always depends, to some tent, upon quantity of production.

Combustion is combustion. It is the me chemical action no matter under hat circumstances it may take place. is the rapid chemical union of oxygen ith the combustible, whatever the latr may happen to be. Light and heat e its manifestations.

In order to avoid confusion at the tset in the use of terms let me first fine the distinction that should be ade between the terms complete comstion and efficient combustion.

Combustion is complete when all of e combustible has been totally conmed or converted in the chemical retion—when there is no combustible in e ash and none in the flue gases. ut while complete combustion is an ement of the most efficient combustn it is not a guarantor of combustion ficiency. Combustions may be comete to the last atom of the combuste and there may be very little of the ing that we call combustion efficiency. c combustion may be incomplete and e combustion efficiency may be very od. Many people think that a smokess stack is an evidence of combustion ficiency, whereas it is very often an idence of the contrary.

We burn fuel because it is the most nvenient way we have of putting heat ergy into the active, usable form. ow while we may get all of the heat ergy out of the fuel and into the tive form we may at the same time do something to render a portion of the heat energy non-usable or non-available, just as non-available as it was when it was in the original fuel in the original geological seam, and more so, because the non-available heat of the fuel in the mine may be rendered available by mining and burning, but the heat that is rendered non-available between the furnace and the heating surfaces of the boiler is lost for all purposes and for all time.

Combustion Efficiency

Here we have a boiler. We want to make steam at say 150 pounds boiler pressure the temperature of the contents of the boiler would be right at 366 deg. F. Now suppose that we have complete combustion in the furnace but that we admit a great excess of air, partly through the fuel and partly through the walls of the setting, and that this excess of cold air is sufficient to lower the temperature of the gases by the time they reach the boiler surfaces of 366 degrees. All of the heat resulting from the combustion would be in the gases, but there would be no flow of heat from the gases to the water in the boiler in excess of that from the water to the gases because there would be no temperature difference into induce the flow. This would be an extreme case, of course, but it is in extreme cases that we find the most clairifying illustrations.

What we call combustion efficiency, and it is a purely arbitrary term, depends therefore upon the completeness of combustion and upon what happens to the heat unit on its journey from the fuel to the boiler heating surfaces. If the heat energy is partly nullified by an unnecessary excess of cooling air the combustion efficiency will be lower than if the unnecessary excess is excluded. Excess air is the greatest of all causes of fuel waste and, in some respects, it is the easiest to eradicate of all of the causes of fuel loss.

Excess air is the air that is taken into the furnace or into the boiler passes in excess of the requirements of combustion. Both complete combustion and efficient combustion require some excess of air because it is impossible in practice to provide such an intimate mixture of air and combustible that there will be no excess of either, but in good practice it is not necessary for us to use more than 40 per cent. excess with a good coal fuel.

Much of the troublesome air excess can be eliminated if we are careful to make sure that the boiler setting is free of leaks. When you get back to your plants make a personal examination of the settings. Take a candle and go all over them, trying the candle flame at everything that looks like a crack. If the flame draws in, plug the crack with cotton waste that has been dipped in a thin mixture of fire clay and water, using a sharpened piece of wood for a calking tool. Examine with particular care all places where brickwork and metal joins, as for example doorframes, furnace fronts, arches at the rear of the boiler, etc. Try the candle where the blow-off pipe passes through the brickwork at the rear of the boiler. Usually there is a sleeve about the blow-off pipe to permit movement induced by expansion and contraction. The space between the sleeve and the brick may be filled with cement or any material, but that between the sleeve and the pipe should be packed with some yielding material, such as asbestos rope. After you have finished calking, cover the brickwork with any one of the several plastics on the market. If you would all do these things I would feel safe in guaranteeing an average fuel saving of 10 per cent.

A great excess of air may, and usually does, enter the furnace through the grate. The next time you enter your boiler room open the furnace doors and look at the fires. They should be dazzling white, but if they appear to be in that condition do not assume that no undesirable excess air is passing through them. There may be large holes in the rear of the grate or on the side of the furnace opposite to the observation door. Use a pair of dark glasses when you are looking at the fire. But the chances are that you will not see a dazzling white fire; it may be anything from that down to a bed of smoldering coals. The chances are that you will notice many cracks and air holes in the fuel bed, with, perhaps, bare places here and there. If it is a stoker with inclined grates the fuel is likely to break apart and slide upon the grates, exposing the naked grates. If it is a chain-grate stoker the fuel may burn faster on one part of the grate than on another. An automatic stoker is no guaranty that the furnace will not be guilty of excess air. Some of the most inefficient plants I have ever seen were stoker plants and some of the most efficient were hand-fired plants. While the days of hand-firing are almost over it is not due to the supreme efficiency of automatic stokers. It is due to the larger capacity that can be secured with them, to the saving of labor that they effect and to the general tendency to work toward mechanical devices. The constant deterioration in the quality of

our fuels has something to do with it and the stoker of the future will be the one that will be able to digest anything, which by any sort of courtesy can be called coal.

While on the subject of stokers it is apropos to say that they are not, strictly speaking, devices for small plants. There is a small plant in my own city, hand-fired at present and employing but one fireman. A stoker is being installed. How can that stoker save any labor. It is a mechanical contrivance and subject to breakdowns in addition to ordinary repairs and depreciation. When it breaks down as it may, some day, the plant will be shut down until it is repaired. I have the word of a leading manufacturer of mechanical stokers that it does not pay to install them unless it can be shown that the labor saving will pay for the equipment within three years. The small plant, and the majority of ice refrigeration plants are small ones should give due consideration to all the factors that enter into the equation before purchasing a stoker.

In getting the thing that we call combustion efficiency I suppose that apparatus counts for about 10 per cent. and operation for about 90 per cent. Hence those of us who are thinking about combustion efficiency all day, dreaming about it all night, are giving more study to the human factor than we are to the mechanical equipment. Think of it a moment:

It is estimated that more than one hundred million tons of coal are wasted every year in the United States because we do not give attention to the practices of the boiler room. Multiply one hundred million by the price you are paying per ton of fuel and you will come to the conclusion that the gigantic rat-hole, known as the Emergency Fleet Corporation, has nothing on the boiler rooms of the stationary plants of our country.

It will be impossible owing to the limitations put upon this paper to go into any of the details that must be observed in getting combustion efficiency. I must confine myself to generalities, and I would have to do that more or less in any event, because each plant presents its own details and in solving the detail problems we must rely upon general principles.

The first requisite of combustion efficiency is a steam plant that has been the subject of some thought before it was installed. The plant must fit the work that it is suited to do. The furnaces and boilers must be suited to each other and to the fuel which must be used. The time will come when steam plants will be limited to short-haul fuel in order to relieve tranportation from its unnecessary burdens. The consumer will not be permitted to haul coal from Pennsylvania to Illinois, for example. He will have to burn Illinois coal. Everybody will be forced to burn the fuel that can be laid down at his plant with the minimum of haul. If you are planning a new boiler plant take that into consideration.

Importance of Proper Draft

The fireman must be educated to good practices and we have said a lot when we speak of educating firemen. What do I mean when I speak of educating them? I do not mean that we should undertake to make combustion engineers of firemen. I mean that we should teach them the things that they must know and that we should insist upon their observance that they should observe. This is not difficult, even with the most illiterate firemen.

Draft is a very vital thing in a steam plant and most plants have more of it than they should use, and strange as is may seem most engineers think they have insufficient draft. The draft must be held down to the requirements of efficient combustion, otherwise an excess of air will be pulled through the fire, the gases will pass across the heating surfaces at too high a velocity and the uptake temperature will be too high.

We cannot set the damper in a fixed position and say we now shall have the right draft, because the conditions that produce draft are subject to constant changes. Draft is affected by the wind, by the barometric pressure, and by the temperature of the gases in the chimney. Other secondary circumstances affect it. Your fireman cannot get the best combustion efficiency unless he knows what draft to use and has a gauge to show him at all times what draft he is actually using. A furnace without a draft guage is like a ship without a compass.

With a fair grade of coal the uptake gases should contain from 12 to 15 per cent. CO_2 by volume, and no Co. When such conditions obtain the air excess is within permissible bounds and the combustion efficiency will be satisfactory. A CO_2 recorder, showing the fireman at all times the efficiency that he is getting, and showing you at the end of the day all of the variations in efficiency during the day, is, in my opinion, one of the requisities of the modern plant, especially the plant that is not under the constant supervision of an expert combustion engineer. The chart from such a recorder enables you to compare the efficiency of each fireman with that of every other one and makes it possible for you to keep in the closest sort of touch with what is going on in your boiler room.

Every team plant should keep its daily records, and these should be sufficiently comprehensive to tell the whole story of the boiler room, The records should cover daily coal consumption and daily average CO_2, together with anything else that may have a bearing upon efficiency, such as daily records of the ash weights and if possible, of the daily evaporation. There is danger sometimes, of carrying the record-making too far. Record keeping should not be burdensome. The records should show the essential things and omit the non-essential.

The average steam plant in the United States wastes 25 per cent. of its fuel. Refrigeration plants are not above the average. You can take one-quarter of the money that you are now spending for fuel and throw it into the dividend account, where it will benefit your stockholders rather than the coal dealer. I submit that it is your duty to do so.

HEATING THE STOREROOM

A peculiar case of improvement in heating is told by a writer in the Dodge Idea. He states that the workmen of a certain firm were complaining about the storeroom not being warm enough. Investigation showed ample radiating surface and that the heating system was working as well as could be expected of it. However, the men kept complaining about it being cold in the passage way between the shelves, which extended up to the ceiling. In the open places it was comfortable.

It was decided that the fault lay in the solid partitions. As a remedy it was suggested that they remove the solid partitions and substitute expanded sheet metal which would allow a free circulation of air. After the change was made there were no more complaints about a cold store room.

In an article by Mr. Daniel Wilson appearing in the Electrician, on "Steam Raising, Yesterday, To-day and To-morrow," it is stated that thirty years ago the maximum steam capacity of boilers was about 7,500 lb. per hour; to-day 130,000 lb.. of steam per hour is attained. America has led the way in large boilers. Engineers in this country prefer distribution in several units. Moderate sizes of 20,000 lb. to 30,000 lb. per hour have been usual, but recently 50,000 lb. to 80,000 lb. units have become common, and boilers for 100,000 lb. per hour (actual) are under construction for the Manchester Corporation. The size of boiler has little effect on unit thermal efficiency. Thus, Detroit Station has an overall thermal efficiency of 16.5 per cent. with 130,000 lb. per hour boilers; in this country 80 per cent. is reached with boilers of moderate size evaporating 30,000 lb. per hour.

The Yarnall Waring Co. of Philadelphia have issued a bulletin describing their Yarway Double Tightening Valves which are suitable for use on acid lines, soot blowing systems, locomotive service and pneumatic systems, in addition to their use as blow off valves The pamphlet is entitled "Tight in Tough Places."

Stationary Engineers' Examinations

We have received so many enquiries from engineers who wish to know the requirements of the Stationary Engineer's Board that we are again printing this information as issued from the Board's offices.

Hoisting Engineer

Mathematics

A knowledge of arithmetic sufficient to solve any simple problem involving multiplication and division:

Boilers

A general knowledge of all types of boilers, dealing particularly with vertical and locomotive types; a knowledge of how and where boilers are stayed; how and where tubes are fastened in place; where manholes and handholes are placed and how plates are held in place; a thorough knowledge of the care and upkeep of safety valves, water columns, water glasses, steam gauges, blow-off valves, etc., together with a knowledge of the cleaning of boilers:

Injectors

A thorough working knowledge of the construction, care and upkeep of injectors, together with a knowledge of how they are connected up and the piping and valves that should be used in connection with them; a knowledge of the conditions under which injectors will operate:

Pumps

A general knowledge of the different types of pumps, both centrifugal and reciprocating:

Engines

A thorough knowledge of the plain slide valve engine; a knowledge of how to set the valves, replace piston rings, together with a knowledge of how to do general repair work on all parts of the engine; a knowledge of how to set eccentrics on reversing engines:

Lifting Gear

A knowledge of the construction and operation of drums, clutches, brakes, pulleys, etc., a knowledge of the sizes of cables, chains, and ropes required to lift certain loads and the power gained by double and triple blocks:

Derricks

A knowledge of the construction of the different kinds of derricks, gin poles, guys, etc., together with a practical knowledge of levers, incline planes, also to possess sufficient knowledge to answer in a practical way what strains would be placed on a boom when at different angles when lifting certain loads:

Combustion

A knowledge of the best methods of burning fuel:

Third Class Engineer

Coal

A general knowledge of the composition of coal, togther with a knowledge of the handling of same:

Combustion

A practical knowledge of combustion; a practical knowledge of hand firing, and a mechanical knowledge of underfeed and over feed stokers:

Boilers

A general knowledge of the construction of all types of boilers; a knowledge of the parts stayed and why such parts are stayed; a thorough knowledge of the care and upkeep of stays, tubes, handhole and manhole joints, fusible plugs, and methods of cleaning and keeping clean all parts of a boiler; a thorough knowledge of the construction and action of safety valves, water columns, blow-off valves, and all accessories connected with boilers:

Boiler Setting

A knowledge of the method of keeping brickwork in good repair:

Piping

A knowledge of the method of keeping pipe-work in good repair:

Steam Engine

A knowledge of the method of setting valves of steam pumps and slide valve engines; a knowledge of the method of proper lubrication and general upkeep of engines:

Steam Turbine

A general knowledge of the lubricating system, governors and throttle valves of steam turbines:

Condensors

A general knowledge of different types of condensors, and where, how, and why they are used; a knowledge of the general care and upkeep of condensor auxiliaries:

Auxiliaries

A general knowledge of the different methods and apparatus used for heating feed water; a general knowledge of why feed water is heated:

Electrical Equipment

A knowledge of the method of operating an ordinary upkeep of generators, motors, etc., together with an elementary knowledge of electricity:

Oils

A general knowledge of the qualities of oils together with the method of treating same:

Heating and Ventilation

A general knowledge of the different methods of heating and ventilating buildings:

Hydrostatics

A thorough knowledge of the construction, operation and care of injectors, boiler feed pumps, and other apparatus used in supplying water to boilers; a general knowledge of pumps used for purposes other than feeding boilers:

Miscellaneous

A knowledge sufficient to give an intelligent answer to any question relating to the uses, care, and operation of throttle valves, non-return valves, steam separators, steam traps, expansion joints, reducing valves, sight feed lubricators, pump lubrication, or any other apparatus commonly used in an ordinary steam plant:

Refrigeration

A general knowledge of the machinery used in ice making:

Water Softening

A general knowledge of the impurities found in water, their effcts on boilers, and method of counteracting them:

Mathematics

A sufficient knowledge of arithmetic to enable him to work problems involving multiplication and division.

First and Second Class Engineer

Coal

A knowledge of the composition, storage, and care of fuel; different grades and heating qualities in same, (togeth-

er with a theoretical knowledge of how the heating qualities of coal are measured):

Ash and Coal Handling Apparatus

A knowledge of the different methods and apparatus used in handling coal and ashes:

Combustion

A theoretical as well as practical knowledge of combustion, together with a working knowledge of CO_2 machines, draught gauges and all other instruments used in testing furnaces underfeed and overfeed stokers, including air ducts, etc.

Boilers

A knowledge of the construction of all types of boilers; a knowledge of how to figure the strength of boiler heads, shells, stays, etc., and to compute the efficienty of boiler joints compared with solid plate; a knowledge of the method of conducting hydrostatic and hammer test of boiler; also, to be able to define terms such as "Bursting Pressure," "Working Pressure," "Factor of Safety," "Tensile Strength," etc.; a knowledge of the method of conducting efficiency test of boilers; a thorough knowledge of all safety and other devices used in connection with boilers:

Boiler Settings

A knowledge of the construction of Dutch ovens, arches, bafflings, and all brickwork in general, including flues, chimneys, etc.:

Piping

A knowledge of the size of piping to be used; a knowledge of the theory and practice of expansion joints, steam separators, steam traps, non-return valves, reducing valves, flow-meters, calorimeters, thermometers, etc.:

Steam Engines

A knowledge of all types of valves and how to set them, (together with a theoretical knowledge of the different types of governors, including safety stop devices; a knowledge of how to figure the horsepower (and steam consumption from an indicator card,) and correct any defect in the setting of the valves; a knowledge of compound and triple expansion engines; a thorough working knowledge of the steam tables, and action of centrifugal force; (a knowledge of the Zeuner or Belgram valve diagram:)

Steam Turbine

A knowledge of the principle upon which turbines are able to convert heat energy into mechanical energy and to be able to describe the bearings, oiling system, governors and auxiliaries used with turbines:

Condensors

A knowledge of the construction of the different types of condensors, together with a knowledge of their auxiliaries and the (theoretical) advantages gained by the use of condensors on different types of engines and turbines:

Auxiliaries

A knowledge of the construction of different types of feed water heaters and economizers, and a (theoretical) knowledge of the precentage gain to boilers in having feed water heated:

Refrigeration

A knowledge of all types of machines used in the compression of air and ammonia, and all auxiliaries connected therewith; also, be familiar with the use of tables of vaporization of gas and be able to explain the theory of refrigeration:

Electrical Equipment

A general knowledge of the care and operation of generators, motors, transformers, switchboards, and house and factory wiring, together with an elementary knowledge of electricity, including meter reading:

Oils

A knowledge of the ingredients and qualities of oils, together with a knowledge of apparatus used in the treating of same:

Heating and Ventilation

A knowledge of the different methods and apparatus used in heating and ventilating buildings:

Water Softening

A knowledge of the different impurities found in water, together with their effect on boilers, and a knowledge of chemicals, apparatus, and methods used for softening water:

Hydrostatics

A knowledge of injectors, pumps, lifts, and all other mechanism used for handling liquids, or propelled by same:

Mathematics

A thorough knowledge of fractions, decimals and square root, and solution of any algebraic equation with one unknown; a knowledge of the method of finding the area of a circle (of segment of a circle,) and the volume of a cylinder, and be acquainted with the relation of the sides of right angle triangles to one another; (a general knowledge of the method of the theory of the parallogram of forces;) a knowledge of the method of figuring problems relating to a chain of gears, rope blocks, incline planes, levers, etc.:

Blue Prints

A knowledge of the reading of blue prints, and the ability to make a working sketch of any point of any apparatus.

The American Engineering Company have issued two new booklets dealing with the Taylor stoker. The first one is entitled "To-day's Problems and the Taylor Stoker" and deals in detail with the construction and operation of the stoker, with plenty of illustrations. The second one is entitled "The Central Station and the Taylor Stoker" and deals as its title implies with the installation of these stokers in large central plants. Another interesting little pamphlet is called "I See a Power Station" and contains a very well written account of a sudden storm and its effect on the load in a central station. These three booklets are an interesting addition to the literature on mechanical stokers.

Toronto—Tenders for the construction of the new east-end branch Technical High School, totalling $771,593, were approved at yesterday's meeting of the advisory industrial committee of the board of education. This figure marks a reduction of twenty-five thousand dollars on the total of the tenders rejected earlier in the Summer. A bulk tender of $607,192 was awarded to Witchell and Sons for twelve trades including masonry, stone, steel, carpentry, roofing, plastering, etc. Plumbing, heating, heat regulation and refrigeration were lumped, being allotted to W. G. Edge Company for $117,000. The next lowest figure for the whole building made up of tenders on individual trades, totalled $780,165. The new school will have a front center section of three storeys, with a wing one storey high to the rear. It will be of fireproof construction throughout and will accommodate approximately 1,000 day pupils and 2,500 night pupils.

Employees of General Motors in Oshawa now number about 1,350. There is not much likelihood that this will be increased in the immediate future, but hopes are entertained that the working force will be enlarged within a few months.

CARELESSNESS

"I am not much of a mathematician," says Carelessness, "but I can add to your troubles, I can subtract from your earnings, can multiply your aches and pains, I can take interest from your work and discount your chances for safety. Besides this, I can divide your thoughts between business and pleasure and be a potent factor in your failures. Even if I am with you only a small fraction of the time, I can lessen your chances for success. I am a figure to be reckoned with. Cancel me from your habits and it will add to your total happiness."—Paron.

Speed, Safety and Durability

These are the characteristics of YALE SPUR GEARED CHAIN BLOCKS that make them popular in machine shops.

Big fellows for placing machinery in position and little fellows swung from jibs for feeding the machines, are all made on the same high standard. With a continuous hand chain guide, the hand chain won't gag or foul from side pull or high speed.

YALE blocks will give you service.

Brownhoist Steel Plate Trolleys either plain or geared should be used with a YALE chain block.

Small sizes with bronze bearings, two ton and over with roller bearings and with four wheels set at the correct angle. An easy running, safe, durable trolley and fit to be used with YALE chain blocks.

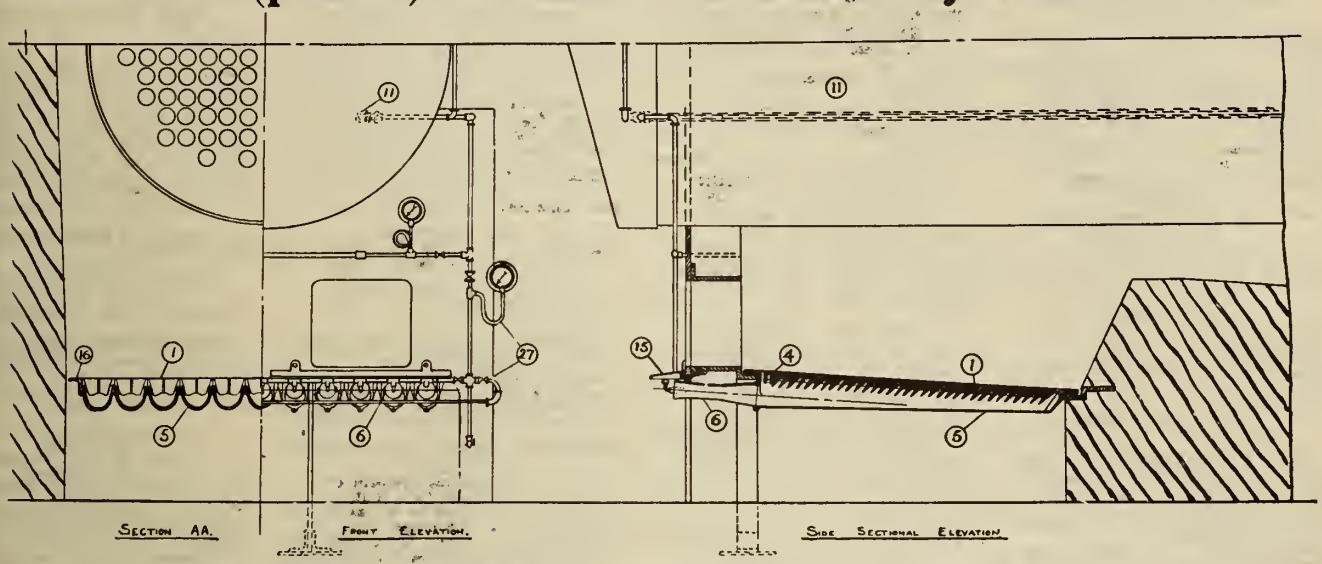
Turbine (patent) Furnace for Externally Fired Boiler



1. Removable fire bars. 5. Air trough. 11. Superheater. 16. Side extension.
4. Locking bar. 6. Air injector. 15. Ash guard. 27. Steam fittings.

Also supplied for internally fired boilers. Write for particulars of the performance of the Turbine (patent) Furnace—using coal slack or coke dust. If you have cheap low grade fuel available let us furnish you with full information at once. Over 1,100 of these furnaces are giving satisfactory service in Britain now.

Manufactured by:

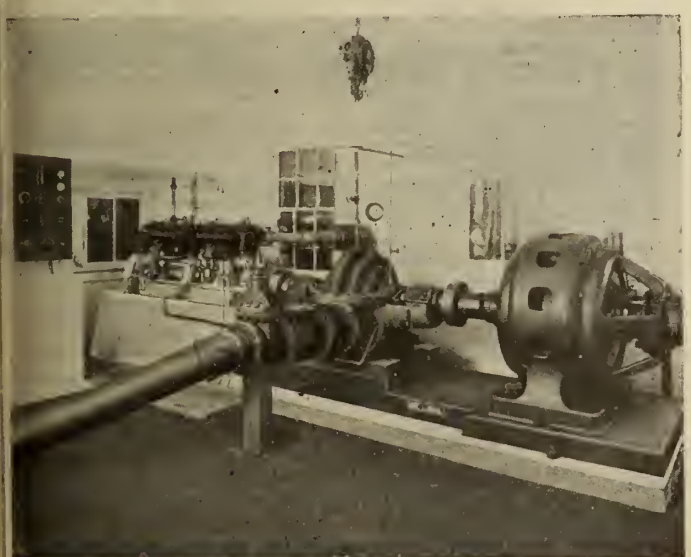
The Turbine Furnace Co. Ltd. London, England

Sole Canadian agent:

PERCY A. GOEPEL, 525 Pender W. VANCOUVER

Consumes no Fuel **Sterling** THE ENGINE of REFINEMENT *For the finest boats that float* While standing by

Is your town paying a terrific cost for maintaining 40 lbs. of steam in a reserve plant for light and fire protection? Why?



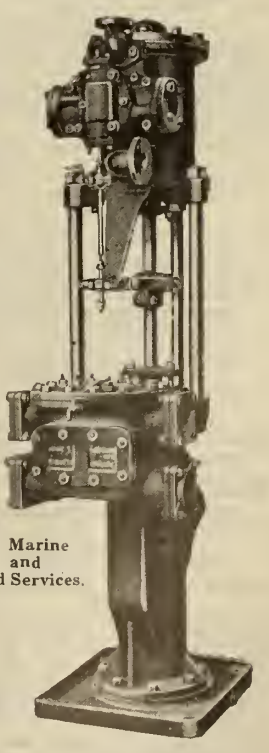
Model FC-8 cylinder 185 H.P. **STERLING** direct connected to DeLaval 2 stage 8" centrifugal pump at Gorst Creek Pumping Station, Bremerton, Washington, as reserve Power. Capacity 1,800 G. P. M., 285 ft. head, speed 1,200 R. P. M.

Sterling Engine Company Dept. C4 Buffalo, N. Y.

Gas and Gasoline Engines. 12 to 300 H.P. speeds up to 1,750 R.P.M.

"SPECIAL" PUMP

WATCH WORK!



And you'll be bound to admit that this Hepburn "Special" Vertical Ram Feed Pump is the most efficient pump you've ever seen. It is a high-pressure, outside-packed type, operating with Outside Lever Valve Motion. The Pump Ram works in a brass sleeve and has only one gland to be packed. It maintains full strokes at variable speeds and there are many other admirable features.

Of course you would like to see this pump in operation—and we want you to. Upon receipt of your inquiry we will forward literature and advise where you may watch this pump under actual working conditions. Better write now.

We also make Vertical Engines, Compressors, Cut Gears and Iron Castings, Overhead Cranes.

For Marine and Land Services.

SITUATIONS WANTED—MALE

IGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration electricity is open for position. Box 17821 er House, Toronto. P. 4. H.

ANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kero- engine. Preferably for small electric light t, able to do own repairs, climb poles and do wiring and take full charge. Apply Box 1. Power House. p.2.h.

STRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any pro- e, stationary or marine. Terms and partic- s on application. Box 13921, Power House. Ph2

PERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work res position. Apply Box 14921 Power House, P2H

FOR SALE

EAM ENGINES, BOILERS, HEATERS. tanks, stacks, pumps and condensers, transion and elevating machinery, safes, vaults and t doors; catalogue and specifications sent on uest. Apply, mentioning "Power House," to lie & McCulloch Co., Ltd., Galt, Ont. (pfh)

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

WANTED

Energetic young man, technical graduate preferred, to represent us now and ultimately take charge of Canadian factory, probably in Montreal or vicinity, making Coppus Turbo Blowers, Boiler Feed Pumps, Steam Turbines, and other power plant specialties. No need to apply if you are looking for an easy job,—we want someone who is willing to work hard with the expectation of a bright future. In writing, state age, experience, and give references if possible and other qualifications.

COPPUS ENGINEERING & EQUIPMENT CO.
Worcester, Mass., U.S.A.
p.1.h.

Chimney Repair Work

Does your chimney need repairing? Experienced chimney foreman and expert repair man is open for engagements. Put your problems up to me. Rates reasonable.
Box 203, Power House.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West. Toronto.

FOR SALE—ONE 16-INCH, ONE 24-INCH Sheldon exhaust fans, practically new. Apply, Box 205. Power House.

SAWMILL MACHINERY MANUFACTURED by sawmill machinery specialists. Apply, mentioning Power House. The E. Long Manufacturing Co., Limited, Orillia.

MONCRIEFF'S

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is **economical.** British Made.

"UNIFIC" WATER GAUGE

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

GLASSES

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Canadian Representative: **W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA**

STOP

Cleaning Fires By Hand

CoKal Hand Stokers save fuel, save labor and eliminate that hot, dirty, disagreeable job of cleaning fires. Also increase evaporation and efficiency.

Send for Illustrative Bulletin.

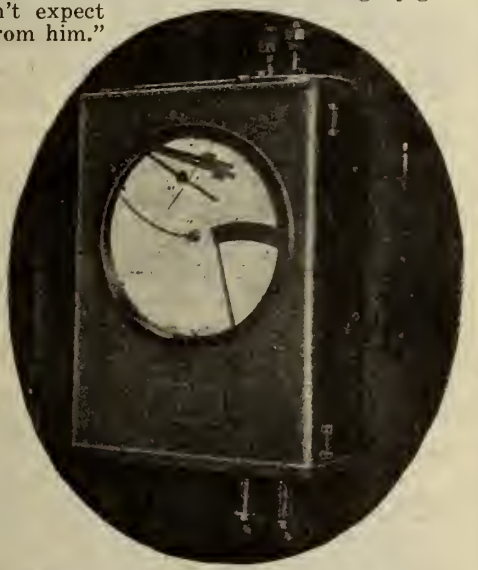
Something Wrong?

"Yes—but what? One of our units isn't producing up to par but I can't find out which it is. Jones is a mighty good man but we can't expect the impossible from him."



We Could Find Out in a Second with

BAILEY BOILER METERS

Because Bailey Boiler Meters accurately record on easily read charts the performance of the individual boilers. Every hour, every minute of the day Bailey Charts indicate faithfully when cleaning or inspection is necessary.

Furnace operation is also carefully recorded. The charts show the Steam Flow in red, the Air Flow in blue and the Flue Gas Temperature in green. Absolutely reliable, the Bailey way is the Economy way.

Let us tell you the story. It's complete in the Bailey Bulletins.

Bailey Meter Company

2001 E. 46th St., Cleveland, Ohio.

Ever Have Material Spoiled By a Slip-Up on Temperature

It's a common and often costly occurrence when temperature is gauged and regulated by hit-or-miss guesswork—and it occasionally occurs with the complicated automatic controls that easily get out of order.

But it simply can't happen with a Sarco Temperature Regulator on the job.

Set the Sarco at any desired temperature from 32 deg. F. to 300 deg. F., and exactly that temperature will be maintained from beginning to end of the process—the slightest variation above or below will instantly and invariably be corrected. No watching, no attention of any kind.

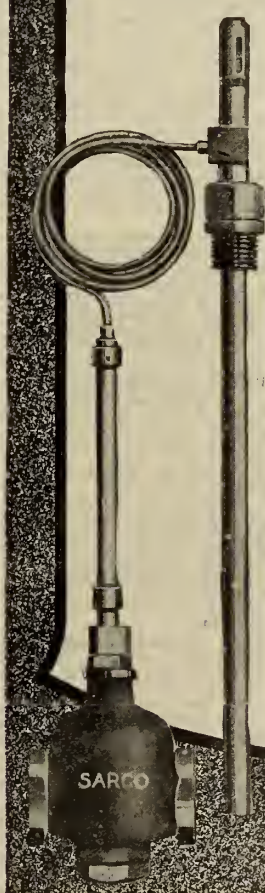
SARCO

Temperature Control

is a revolutionary improvement in automatic heat control—revolutionary in its simplicity, revolutionary in its absolute certainty and dependability.

Entirely self-contained and self-operating—operates through a system of **liquid** expansion and contraction that is as sure as the law of gravitation. No electricity, no compressed air or water, no outside attachments or outside aid of any kind.

Sarco costs less than any other heat control on the market—because so simple. Also much easier to install.



And this same simplicity is what makes Sarco so dependable in operation—nothing that can deteriorate or lose efficiency.

Sarco Temperature Regulators operate on either gas, steam or hot water heat. They can be supplied to meet the requirements of practically any manufacturing process — including the most delicate. Also for control of room temperature in hotels, apartment houses, etc.

Sold on 30 days' free trial—if not satisfactory, simply return it and it costs you nothing whatever.

For further information write for Booklet No. J-52, which includes full particulars about our free trial offer.

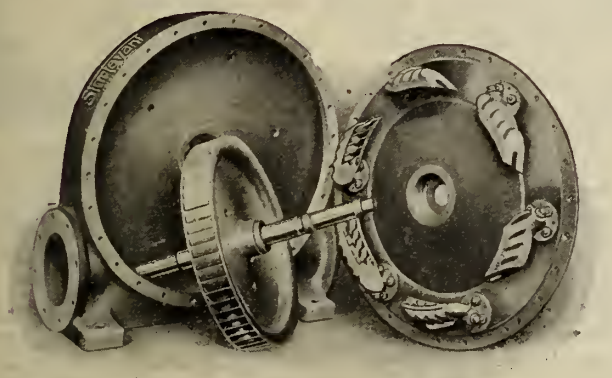
For Low Cost in Operation



Sturtevant Turbine dissembled, showing solid milled turbine wheel, reversing chambers and casing

Sturtevant

"Trade Mark"

Steam Turbines

are well adapted for driving

auxiliary equipment

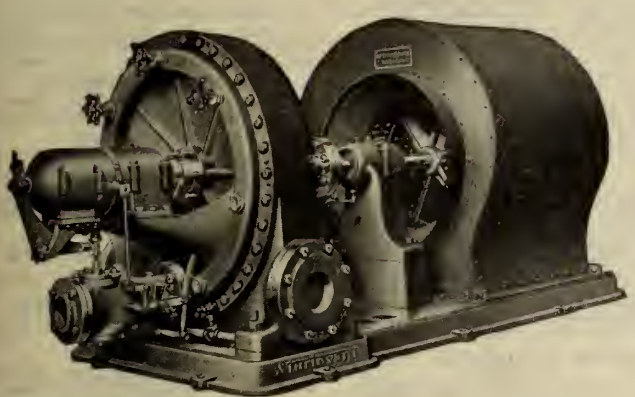
Their excellent record in reliable operation under difficult conditions with a high steam economy maintained under variable load.

The care taken in providing an unsurpassed dynamic balance insures smooth operation and minimum wear in service.

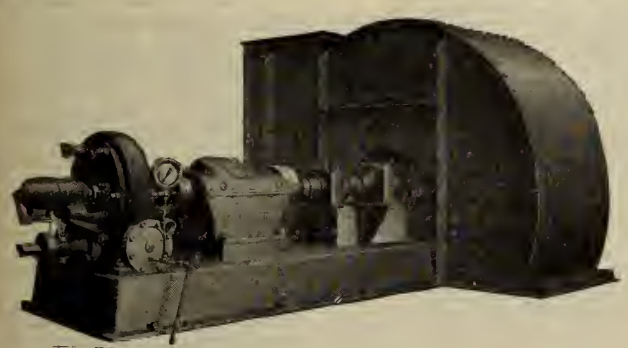
In safety and close speed regulation, the improved governing mechanism has proved itself distinctly superior for this class of small turbines.

Accessibility to all interior parts facilitates routine inspection.

Plant managers and operating engineers should write for Turbine Catalog "V."



Sturtevant Direct-Connected Turbine Fan



Sturtevant Induced Draft Fan driven by Sturtevant Turbine and Reduction Gear

Sturtevant

PUTS AIR TO WORK

Mechanical Draft Equipment

The successful operation of the modern boiler plant depends primarily upon the certainty by which the fires receive the proper air supply at the lowest possible cost.

Sturtevant Forced Draft Fans cover a complete line from the small undergrate blower to the most powerful types for large underfeed and chain grate stokers.

All represent the development of high grade engineering design and unsurpassed construction that insure the maximum in dependability. They can be furnished in units, either steam turbine, steam engine or electric motor driven, built and assembled in the Sturtevant plant and backed by the Sturtevant guarantee.

Sturtevant Induced Draft Fans are designed with a view for maintained economy and low upkeep cost in handling large volumes of hot gases. For chain grate and overfeed stokers and hand firing their installation will result in increased capacity and high flexibility in boiler operation.

Consult the Sturtevant engineers in regard to every draft and ventilating equipment problem in your plant.

Write for catalogs covering this line.

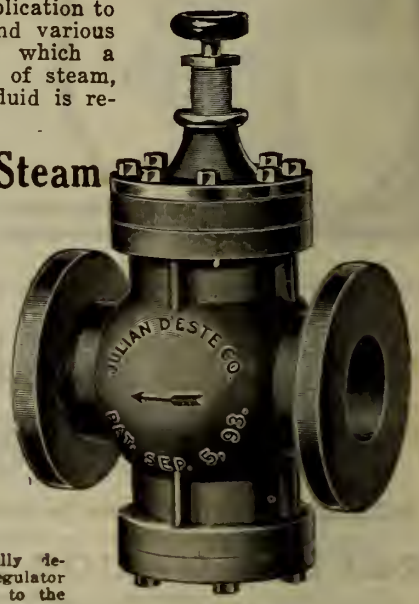
Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the



Improved Steam Pressure Regulator

has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

Mr. President or Managing Executive.

BECAUSE Superheated steam offers such remarkable returns in economy on such a small investment and because it can be applied to existing or new plants with such ease, it commends itself to the executive who is striving for low plant operating costs.

At a time when curtailed expenditures are necessary, every dollar invested in power plant equipment must yield the highest returns. By converting existing saturated steam plants to operate on superheated steam, a simple conversion, a higher return per dollar invested in the original plant accrues while the superheater installation itself returns its installation cost.

In reducing fuel consumption, Elesco superheaters reduce manufacturing costs by increasing boiler capacity. Elesco superheaters save the expense of new boilers when manufacturing requirements demand increased power plant capacity.

Let us get into this with your engineers and work with them so that we may give you a dollars and cents report of the savings Elesco Superheaters will make in your plant.

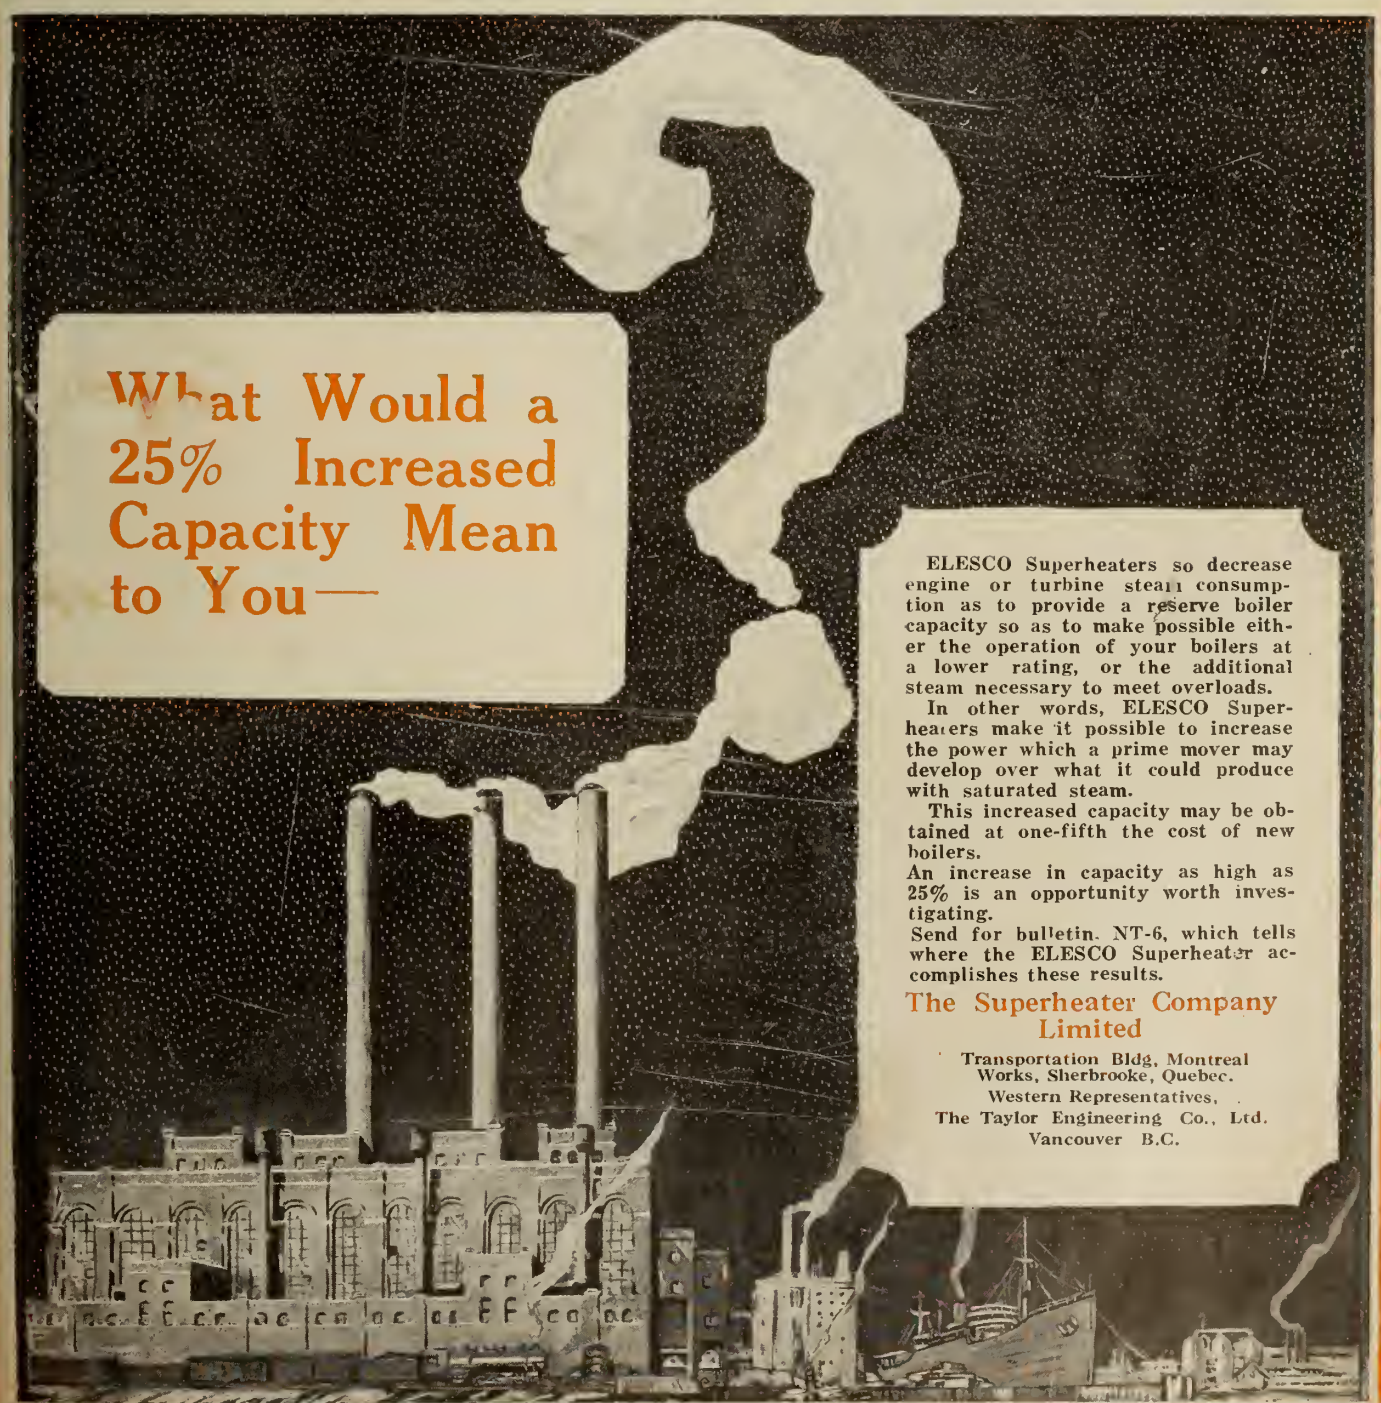
MONTREAL: Southam Building LONDON, ENG.: 88 Fleet Street, E.C. WINNIPEG: 901 Confederation Life Building

Vol. XIV.—No. 19. Publication Office, Toronto—Oct. 5, 1921 Published Semi-Monthly Canada, $2; U.S. $2.50 a year

ELESCO SUPERHEATERS



ELESCO Superheaters so decrease engine or turbine steam consumption as to provide a reserve boiler capacity so as to make possible either the operation of your boilers at a lower rating, or the additional steam necessary to meet overloads.

In other words, ELESCO Superheaters make it possible to increase the power which a prime mover may develop over what it could produce with saturated steam.

This increased capacity may be obtained at one-fifth the cost of new boilers.

An increase in capacity as high as 25% is an opportunity worth investigating.

Send for bulletin. NT-6, which tells where the ELESCO Superheater accomplishes these results.

BOWSER
ESTABLISHED 1885
PISTON-TYPE MEASURING PUMPS

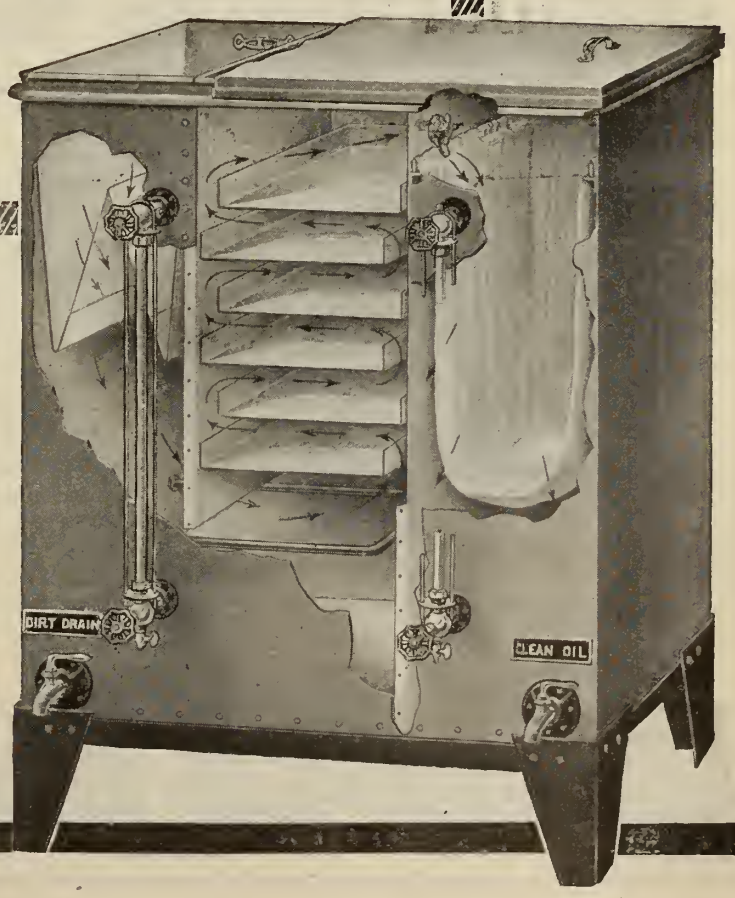
THE LIFE BLOOD OF THE FACTORY

Dirty, gritty lubricating oil will junk your machinery long before its time. **Friction is production's worst enemy,** and the wear and tear caused by dirt and grit in oil slowly but surely wears out expensive bearings and other machinery parts.

Clean oil prolongs the life of machinery. Bowser Lubricating and Filtering Systems assure clean filtered oil on all bearings and restore the oil to its original lubricating quality. Try the Bowser Perfected Process of Seepage Filtration.

Installation takes a minimum of floor space.

There is a Bowser System for every oil filtration requirement. Also complete oil storage and handling equipment.



Write for Illustrated Booklet C-21

Bowser Equipment is MADE IN CANADA.

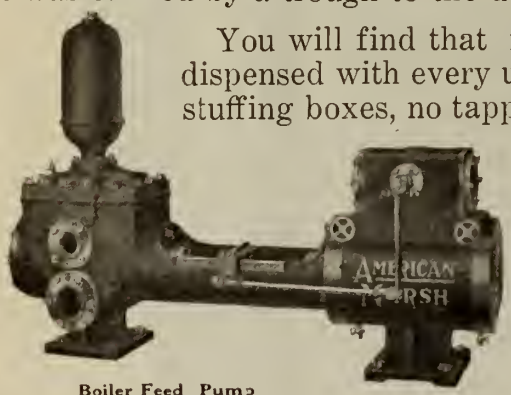
PUMPS

The Noria was used in a number of ancient countries—China, Palestine, Syria and Spain.

The Noria—a type of ancient waterwheel—dispensed with the usual oxen. It was driven by the running stream—acting on floats or paddles. A "trip" emptied the contents of the buckets into an elevated tank, from which point it was carried by a trough to the ditches below.



Boiler Feed Pump

You will find that modern American-Marsh Pumps have dispensed with every unnecessary part. There are no internal stuffing boxes, no tappets, and no slide valves.

Write for bulletins.

Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.

Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

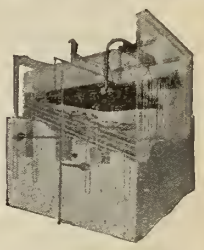
DIAMOND
VALV-IN-HEAD
SOOT BLOWERS

At every point the Diamond Valv-in-Head soot blower effects important savings. For example: Its use assures 100% cleaning efficiency, thus putting many additional dollars a year, as the result of decreased fuel consumption and better boiler efficiency, in the owner's pocket.

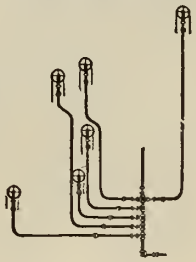
With this system the cost of operation and maintenance is from 1-3 to ½ that of independent valve systems, making it very profitable to replace the ordinary revolving soot blower heads with the new Valv-in-Head.

Consider the matter of pipe, valves and fittings on new installations. A saving is effected of practically 2-3 in the actual length of pipe required. The elimination of expensive individual control valves in favor of the Valv-in-Head is an important cost consideration. This decreases the initial cost of these items by ½ to 2-3 and reduces radiation losses from the soot blower lines proportionately.



Valv-in-Head System—25 feet of pipe, no independent valves.

On a typical six unit installation, with the independent valve system 83 feet of pipe and six 2″ individual control valves are required. With the Valv-in-Head only 25 feet of 2″ pipe and no individual valves are required. With this six unit installation the saving in cost of pipe, valves and fittings effected by the Valv-in-Head system is approximately 64 per cent. The comparisons are: ....



Independent Valve System—83 feet of pipe, six 2″ valves.

Using "Bronze body valves, nickel seats and discs."

Independent valve system	$249.44
Valv-in-Head System	90.83
Saving by latter	$158.61

Every boiler needs a mechanical soot blower and you will save money by buying the best. Diamond Valv-in-Head blowers are adapted to all types of water tube boilers. On request our Service Engineer will go over your existing soot blower installation and advise whether it can profitably be replaced with the Diamond Valv-in-Head system.

Ask for your copy of Bulletin 287 describing the new blower.

SOOT BLOWERS - SAVE 4 to 8% FUEL

New Truths and Old Fallacies

Lubricating Quality--*Continued*

Some years after the United States Government tested Magnolia Metal, the French Government also became interested and made an elaborate test of it, resulting in its endorsement for use by the French Navy.

In this test with "black lubricating oil," 710 lbs. load per square inch, 6.56 feet per second, the frictional co-efficient was 0.0012.

In 1912 Professor Robert H. Smith, before referred to, tested Magnolia Metal with water lubrication and in his report says: "This test proves that bearing A (Magnolia) can be easily run continuously at over 130 lbs. per square inch load at from 400 to 450 R. P. M. with water lubrication."

While it was never expected or claimed that Magnolia-lined bearings could be run independent of lubrication, the tests by the Government and Professor Smith and occurrences in actual service lead to the conclusion that it can be done successfully in many cases.

Mr. Martin L. Baldwin, founder and machinist, St. Clair, Michigan, recently reports having been called, during the night, to re-metal the bearings of engine of the City Electric Light plant. He used Magnolia, and in his hurry to start up the engine he forgot to provide oil hole and grooves. To use his own words, he said: "In the morning my mistake occurred to me, so I hustled to the plant and to my astonishment found engine running as smooth as glass and not heating. We ran engine a number of days before taking apart again."

Another case reported to us occurred in the establishment of Mr. George A. Diemer, Newburgh, N. Y., where Magnolia bearings on a head shaft for motor drive have not received a drop of lubrication in over twelve years, and very likely are still running. That Magnolia will save in lubrication is a matter of course and is mentioned too often to excite notice and naturally the deposition of small particles of worn metal in the oil recovered will be comparatively slight.

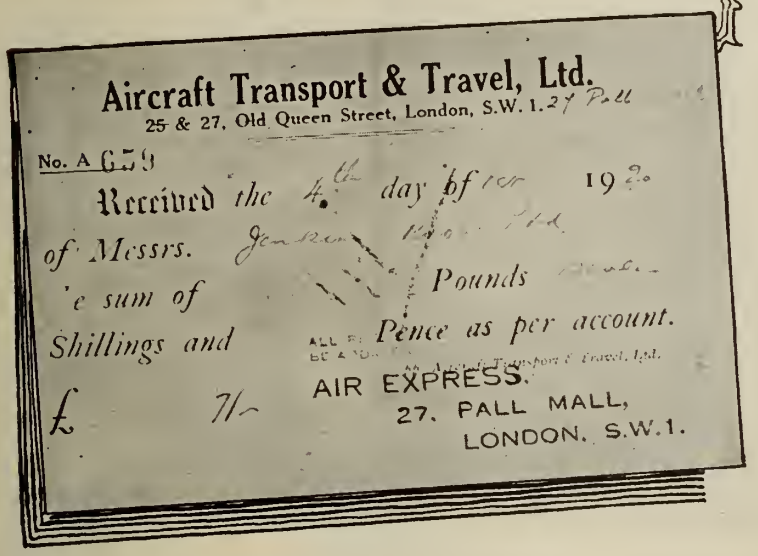
"SHIP BY AIR" —*We did*



Aircraft Transport & Travel, Ltd.
25 & 27, Old Queen Street, London, S.W. 1.
No. A 659
Received the 4th day of Oct 1920
of Messrs. Jenkins Bros Ltd
the sum of Pounds
Shillings and Pence as per account.
£ 11-
AIR EXPRESS.
27, PALL MALL,
LONDON, S.W.1.

Messrs. Peck & Co., of Amsterdam, Holland, wanted Jenkins Valves—and needed them in a hurry. Their order said "Ship by Air." Our London office dispatched the valves by aeroplane over the North Sea to Amsterdam, where they were received by Messrs. Peck & Co. the same day.

Among experienced engineers and those who know valves and valve requirements there is no substitute for Jenkins Valves—they are valves of established dependability that may be placed in service and forgotten as far as trouble is concerned.

Jenkins Valves benefit by over half a century of valve manufacturing experience. That their design and construction is correct has been proved by performance for many years. More metal, and the best metal, is put into Jenkins Valves—it is properly distributed—there is no weakness at any point. Each valve in every type is safe and dependable in the unusual as well as usual service.

Jenkins Valves are obtainable through supply houses everywhere—the genuine have the name and Jenkins "Diamond" cast on the body—without this identification a valve is not a Jenkins. Avoid imitations.

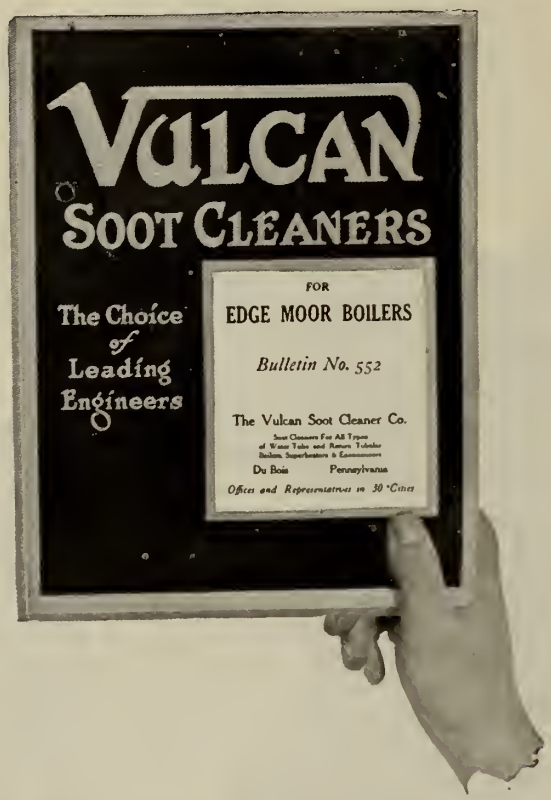
Keeping Your Winter Coal Costs Down



Clean heating surfaces are a guarantee that each unit of heat will accomplish its expected purpose of turning a given quantity of water into steam.

Dirty heating surfaces are equally a guarantee that many units of heat will fail to register.

Dirty heating surfaces, therefore, reduce the producing value of every dollar's worth of coal burned. In many cases this reaches as much as 10% to 25% of the total coal consumption.

Vulcan Soot Cleaners keep the heating surfaces clean and free from soot, thereby giving ALL the heat its proper chance to turn the water into steam. They are at least 50% more effective and more thorough than ordinary every-day hand lance cleaning, are easier to handle, perform their task quicker and with less labor, and entirely eliminate the dirty, disagreeable work of hand cleaning.

Vulcan Soot Cleaners are, in this day of conservation and the strictest economy, a really substantial dividend-paying investment.

The Bulletin illustrated is No. 552, describing the Vulcan Cleaner for Edge Moor Boilers. Other Bulletins are: No. 534, for Return Tubular Boilers; No. 547, for Wickes Boilers; No. 548, for Stirling Boilers; No. 550, for Connelly, Badenhausen and Erie City Vertical Boilers; No. 556, for Keeler, Geary and Union Boilers; No. 541, for B. & W Boilers. (No. 541 also applies to Goldie & McCulloch Boilers.)

We shall be glad to send you the Bulletin applicable to your boilers.

Saving a Cent a Pound -- or Twenty

by buying babbitt, which lasts only half as long as Ajax Bull Bearing Alloy, is not economy. It's sheer waste.

The babbitt itself is a minor item in the expense of rebabbitting. It's the time and production you lose while the machine is shut down. Labor costs don't stop, overhead keeps on piling up. Nothing goes down but the net profits.

AJAX BULL BEARING ALLOY

wears longer than any babbitt metal because it's made of virgin metals by the Ajax Alloying Process.

Has been used extensively by makers of Heavy Mill Machinery, and several Canadian Mills have adopted it exclusively.

Firing that is Different

WITH the RILEY STOKER the coal is fed—the fire cleaned—the ash discharged, ***continuously and automatically.***

All done without waste or effort, efficiently and economically.

It is not only the things the RILEY STOKER does but the way it does them. For instance, when steam is wanted quickly, and time is precious, you can get this steam instantly and economically by increasing the motion of the grates.

With the first turn of the cranks the grates start moving—the whole fuel bed is thrown into action. There is no watching nor waiting—poking nor slicing—the stoker responds instantly and in two or three minutes the boiler will be operating at 200 or 250% of rating.

It is this kind of flexibility that saves not only for the central station but for the industrial plant.

RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

P⊗H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the out side diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

What is Your Idea of a Good Investment?

TEN per cent. is a good return; it pays out in ten years. But, by saving 80% of the refrigeration lost from uninsulated brine and ammonia lines, Nonpareil Cork Covering pays back its cost in *one* year or less. The return is 100%. For long lines or short ones, large pipes or small, it figures out that way. Local conditions may vary it slightly, but on the average that is the result.

In your own plant, for instance, you can either *lose* the value of the wasted refrigeration, or you can *invest* it in Nonpareil Cork Covering. In the one case, there is no return; in the other, the saving effected pays back the entire investment, not only the first year but every year thereafter for the life of the covering.

And remember—"Lasts Longer than the Pipe" is not a catch phrase, but an actual fact, truthfully descriptive of the remarkable durability of Nonpareil Cork Covering.

8-inch ammonia suction line insulated with Standard Brine Thickness Nonpareil Cork Covering and weatherproofed for outdoor service. Shreveport Ice & Brewing Company, Shreveport, La.

Nowhere else is there available so much accurate information on the insulation of cold lines as you will find in the 64-page book "Nonpareil Cork Covering." If you have bare or inadequately insulated lines, by all means send for this book. There is no charge.

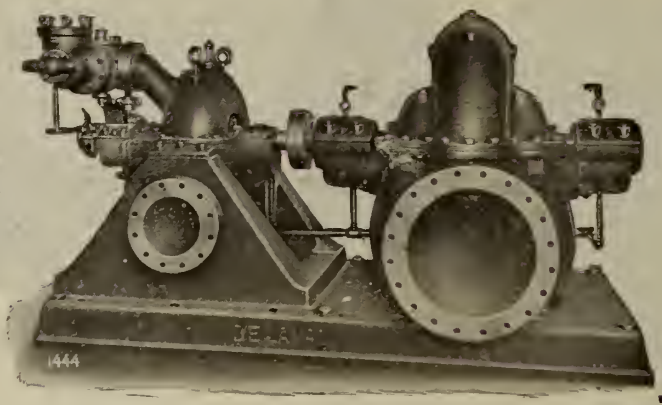
STAMINA



De Laval velocity stage turbine driving blower; 18,000 cu. ft. per min. against 40 in. water column, 3,600 r.p.m.

THIS DE LAVAL CENTRIFUGAL BLOWER driven by a directly connected steam turbine can be depended upon. It is simple and substantial. The blower casing castings are extremely heavy and the impeller and shaft are made of alloy steel. Large bearings and a pressure-oiling system insure reliable lubrication. The turbine is similarly simple and rugged. All working parts of either machine are accessible upon lifting the casing covers. The turbine is controlled by a simple and effective governor and valve gear. Hand-operated nozzles are provided to secure maximum efficiency at different loads.

De Laval blowers are built for all capacities and for all pressures up to 125 lb. per sq. in. De Laval turbines are used for driving all kinds of machinery at all speeds. State nature of your service and suitable literature will be sent.

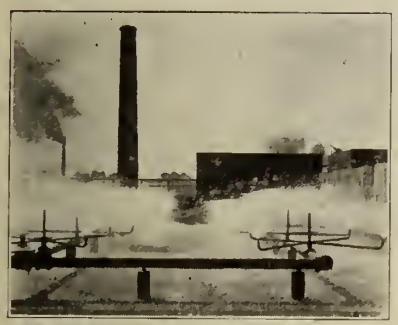
"SPRA-RITE"



Iowa Railway & Light Co., Marshalltown.

Most Advanced System for Cooling Condenser Water

COOLING systems representative of the best practice a decade ago are virtually obsolete now. "The SPRA-RITE" System fills the bill today, meeting as it does all the requirements in the shape of capacity, flexibility and cooling efficiency.

SPRA-RITE TWO-VANE NOZZLE

The function of the SPRA-RITE is to discharge a fine spray of equal density throughout its entire cross section.

SPRA-RITE Cooling Systems have proved their efficiency. Tests made on the coal pile by means of the increased vacuum obtained prove that many systems have made a 50 to 100 per cent. return on the original investment in a year's time. Frequently a reduction in insurance rates is also obtained by reason of ample water supply close at hand for use by fire pumps.

We will be glad to furnish complete information respecting SPRA-RITE

THE ARTHUR S. LEITCH CO.

LIMITED

1001-2 KENT BUILDING, TORONTO, ONT.

Mason Standard Reducing Valve Bronze Body

Where Uniformity of Steam Pressure *Must* Prevail Use

MASON STANDARD REDUCING VALVE

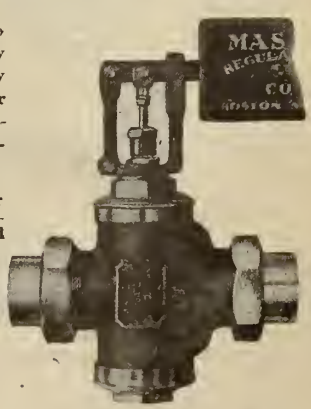
A SPECIAL socket key permits them to be set to constantly maintain any required pressure within a wide range. Once set, no further attention is necessary.

The all-bronze patterns made in sizes from ½ in. to 2 in., inclusive, will reduce any working pressure, if not more than 300 lb., down to 5 lb. in a single reduction. The iron body bronze mounted types are made in sizes from 2½ in. to 10 in. inclusive for initial working pressures up to 180 lb.

Mason Reducing Valves automatically reduce boiler pressure for steam heating systems of all types (vacuum systems included), central heating plants, engines, paper machines, dye kettles—all situations where it is desirable to use lower pressure than that on the boiler.

MASON Reliable Self Closing Balanced Valves

They can be thoroughly relied upon in any situation requiring a valve to be operated with a minimum amount of power. They are self-closing by means of the weight, and the length of the lever causes them to slowly open. Used to control pumps, engines, etc., by the means of tank floats or cords to distant points, and also in connection with various devices for controlling the flow to water wheels, receivers, open heaters and other similar devices.



Mason Balanced Valve

The MASON line includes Pressure Regulators for Steam, Air Gas, or Water. Also Hydraulic Damper Regulators for automatically controlling boiler draft. Technical description and engineering advice gladly submitted.

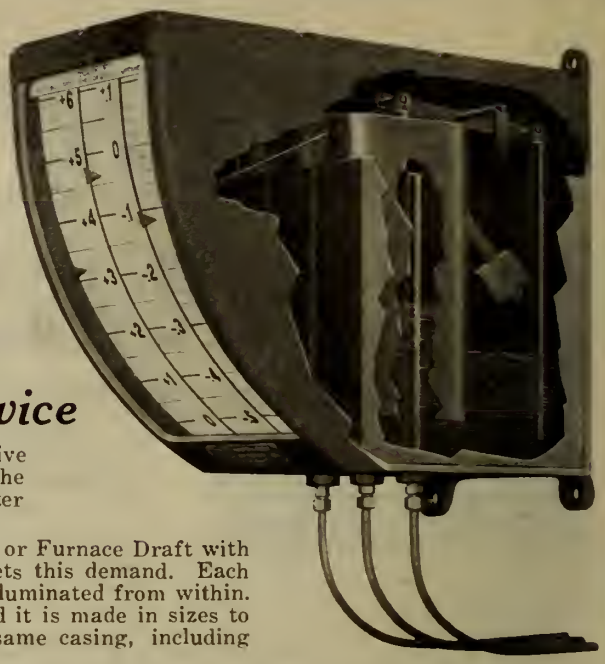
BAILEY

Multi-Pointer GAGES



Distinctly New and Valuable Device

These Gages were developed to supply a demand for a sensitive and accurate draft gage. The design is practically the same as the Fire Box Draft Indicator which has been in use on our Boiler Meter for several years.

With forced draft it is highly necessary to maintain the Fire Box or Furnace Draft with an accuracy of 0.01 inches of water. The Multi-Point Gage meets this demand. Each pointer has a 10-inch motion along the arc of a scale which is illuminated from within. The gage can be read with accuracy at a distance of 20 feet, and it is made in sizes to accommodate any required number of separate pointers in the same casing, including 2, 3, 4, 6, 8, 10 and 12 pointers.

There are two distinct types of casing used, one for wall mounting, known as Type P2, P3, etc., depending on the number of pointers, and the other design for meter board mounting, known as Type P2F, P3F, etc. The gage is so convenient and easily read that it will be developed to show high pressures, temperatures, stoker speeds and other factors, thus indicating on one instrument all secondary operating conditions.

This distinctly new gage is fully described in Bulletin No. 160—shall we send you a copy?

BAILEY METER COMPANY

Canadian Association *of* Stationary Engineers

Incorporated May, 1887
Incorporated at Ottawa June, 1917

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?

If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.

The undersigned will be very pleased to give any further information required.

F. HARPER, President Grand Lodge.
89 Bay Street, Kingston.

L. J. ELLIS, Sec.-Treasurer Grand Lodge.
142 East Avenue, N. Hamilton.

Why Asbesto-Sponge will stand abuse

Note the laminated construction of Johns-Manville Asbesto-Sponge. These pliant layers give Asbesto-Sponge the ability to retain its high insulating efficiency year after year in spite of conditions that might destroy other insulations.

Send for this Sample

Examine a sample of Johns-Manville Asbesto-Sponge Felted Insulation. See for yourself what it is.

Send for our leaflet giving facts about insulation that you should know.

AN insulation might be the most efficient in existence, but if it were not durable, if it would not stand handling, shipping, accident, even abuse, it would be of no practical use.

For it is the physical strength of an insulation that enables it to continue to render service for a long period.

Insulation that crumbles to powder at a touch; that falls to pieces under vibration or dampness is too expensive for any plant to use, no matter how cheap it may be.

But it is possible to make efficient insulation of great physical strength—that will stand up under all service conditions, and render the maximum of heat saving.

Johns-Manville have been making such an insulation for many years. This is Asbesto-Sponge Felted—composed of many thin layers of asbestos and sponge, felted together.

These pliant laminations utilize the dead-air principle to the utmost degree, making Asbesto-Sponge easily the most efficient insulation. And, in addition, these same laminations give Asbesto-Sponge wonderful elasticity, resilience, and strength to resist handling and mishandling; use and abuse.

Even superheated steam and dampness can do very little harm to Asbesto-Sponge.

You will find that in your own plant Asbesto-Sponge Felted is the kind of insulation that stays on the job long after the ordinary covering has to be replaced.

WAIT STEAM TURBINES

The Acme of Perfection

MANY recent improvements in detail by skilled investigators have resulted in the G. & McC. Co. "Wait" Steam Turbine reaching a high point in efficiency—it is in fact recognized by leading engineers as the acme of perfection in steam turbines. Some of its leading features include in addition to high efficiency—simplicity, ruggedness and economy of operation.

Points of this **G. & McC. Co.** *Machine that should be remembered are:*

—The Turbine is entirely automatic.
—No oil or grease cups.
—Stuffing boxes and glands seldom require attention.
—Emergency governor and valve are entirely separate from main governor and valve.
—Interior may be easily inspected.
—Self-lubricating; dust proof; dirt-proof.
—Speed can be changed while running.
—LOW RUNNING EXPENSE AND COST.

A Review of Power Plant Evolution

Limit of Development Along Old Lines Practically Reached—Ferranti's Proposed Turbine Cycle—The Emmet Mercury Boiler—Results Effected by Employment of Mechanical Stokers—Economiser Problems—Feedwater Heating

By *C. F. HIRSHFIELD, DETROIT

FEW people who are not directly interested realize the tremendous extent to which both modern industrial life and modern family life are dependent on electric energy, or electric power as it is more commonly called. The revolutionary changes in industrial methods which followed the introduction of the water wheel and steam engine have been treated extensively in literature, and almost everyone who reads and thinks knows that the entire social structure of today rests, ultimately, on these prime movers. The part played by electric power, however, has not been so widely advertised and is not so well appreciated.

It is practically impossible to obtain accurate and complete data of the electric power output of the country but it may be stated that the per capita consumption of central-station power has increased from 23 kw-hr. in 1900 to 435 kw-hr. in 1920. These figures represent the growth over a fairly short period and are indicative of the rate at which electrical power has come into use in the country as a whole. As a matter of fact, however, they do not tell the whole story, because much of the electric power used by street railways is not included and because the total population of the country has been used as the divisor. Since the greatest use of power is in the large and small industrial centres, division by the total population of the country gives too small a figure.

To indicate the significance of this feature Fig. 1 is presented. This figure refers to the city of Detroit, which has had a most remarkable growth, and it is therefore not properly representative of all industrial centres, indicating a somewhat extreme case.

Obviously the production of power by central stations is one of the important items in modern life, and the increasing extent of its use has reacted upon the industry of power generation in a most remarkable way. In the case of fuel-burning stations, to which these observations are confined, the development of most economical apparatus, the improvement of load factor, and the refinement of operating methods have all been such that there has been almost continuous decrease in the cost of production per unit of output. It should be understood that this decrease results not only from the more economical use of fuel but also from better use of capital and labor. It is of course common knowledge that the selling price of electrical energy has recently risen in practically all parts of the country. This has been due to abnormal prices of all materials, supplies, and labor, as well as to the attitude of labor toward work. These things are probably all temporary, and it is expected that their effects will disappear in due time.

Three things have had a predominating influence in bringing about these results, namely—

a. Improved load factor
b. Increasing size and efficiency of steam turbo-generators, and
c. The introduction of efficient mechanical stokers.

It is difficult to give average values for the purpose of showing load-factor improvement because conditions vary greatly from place to place and time to time. However, it will help somewhat to point out that as a central electric supply changes from a pure lighting to a combined lighting and power supply, the load factor changes from something of the order of 10 per cent or less to a value between 50 and 70 per cent. Obviously capital charges per unit of output in the first case are extremely heavy when compared with capital charges in the second case.

The size and efficiency of steam turbo-generators are, of course, readily expressed in numerical form. Fig. 2 is given to illustrate the marvelous developments which have occurred within two decades.

The introduction of efficient mechanical stokers has had two quite different effects. The boiler-room thermal efficiency has been increased to a remarkable degree and the size of units has grown tremendously. In 1900 most central stations were equipped with boilers containing not over 5,000 sq. ft. of heating surface. This size has been increased gradually until now units containing between 12,000 and 24,000 sq. ft. are in common use. Paralleling the increase in thermal efficiency and in size, there has been an increase in the efficiency of use of boiler-room labor. It is now possible for one fireman to take complete charge of 5,000 rated boiler horsepower.

Limit of Development Along Old Lines Practically Reached

At the present time we seem to have reached very close to the limit of ultimate development along the lines which have been followed during the past two decades. This statement, however, is not meant to imply that there is no further room for improvement in central stations as they now exist. Obviously, no central station not built within the past year or two can contain all the latest developments. Almost all central station companies operate one or more old plants which could be improved by reconstruction. In many cases this reconstruction can be economically justified and is being carried on or is contemplated. Nor does it mean that we are unable to build more efficient plants than those just completed.

The real significance of the statement is this: Since about 1900 we have pursued a fairly consistent sort of development along fairly definite lines. During the entire period further possible improvements were always visible and one could predict with a reasonable degree of certainty that each suceeding year would produce certain definite modifications and advances. Now we seem to have reached a point where marked increase of economy in the use of money, labor or fuel can be made only by radical changes of some sort.

*Chief, Research Department, The Detroit Edison Company. Mem. Am. Soc. M.E.

Presented at a meeting of the Cleveland Section of The American Society of Mechanical Engineers, March 1, 1921. Slightly abridged.

Rather curiously we arrived at this point in the evolution of the art at just the time when there was the greatest need of conservation in the use of capital, fuel and labor. The driving force furnished by the excessively high prices for money, fuel and labor which have characterized the last two or three years would have been sufficient to cause improvements of tremendous magnitude had we known just what direction to take. Unfortunately we found ourselves at a sort of parting of the ways, and the best brains in the industry in this country and in Europe have been, and are, trying to map the road to be followed in the immediate future.

Out of the work already done have come several definite indications, but the author cannot feel that any of them promise enough to justify us in concluding that they mark the way. Rather are they to be considered merely as the finishing touches to the existing type. It is his belief that we are just polishing off the steam-turbo-generator type, and that while we may be forced to continue doing so for quite a few years, we are essentially marking time while waiting for a new, epoch-making design, invention or development.

There is nothing now in sight which promises any change so revolutionary as the introduction of the steam turbine or the stoker, but this must not be interpreted to mean that the author does not believe something of this sort is coming. He feels perfectly certain that development will be even more rapid in the future than it has in the past and that, as a result, the allowance for obsolescence should be made higher in the future rather than lower. With the foregoing paragraphs to serve as an introduction we may now enumerate and possibly evaluate the changes now occurring and those which are apt to occur in the near future.

All engineers who are familiar with the theory of steam engines and other heat engines know that theory indicates increasing thermal efficiency as upper and lower temperatures of the working substance are moved farther apart. In the case of the steam turbine this is equivalent to saying that the thermal efficiency will improve as the temperature of the steam reaching the unit is raised and as the back pressure, and therefore, the temperature of steam leaving the unit, is decreased.

We already have many stations operating with maximum steam temperature of 600 deg. Fahr. or higher and we are rapidly approaching a temperature of 700 deg. A value between 700 and 800 is generally considered to be the highest that should be used with the metals and alloys and the types of construction now available. In the opinion of the author 700 deg. Fahr. is about as high as we can safely go at present.

At the other end of the temperature scale, we are now operating our best plants with an average back pressure throughout the year of about one inch of mercury, and there does not seem to be any possibility of greatly improving this performance.

Economic Possibilities in Use of Higher Steam Pressure

With the temperature limits thus definitely set and already practically attained, engineers have begun to consider seriously the possibilities of using higher steam pressures without exceeding the upper temperature limit. It is commonly known that the temperature of saturated steam increases with pressure, but the form of the curve connecting pressure and temperature is not generally appreciated. Such a curve is given in Fig. 3. It is obvious that temperature increases very rapidly with respect to pressure at low pressures, but that this relation is reversed at high pressures. At present a few central

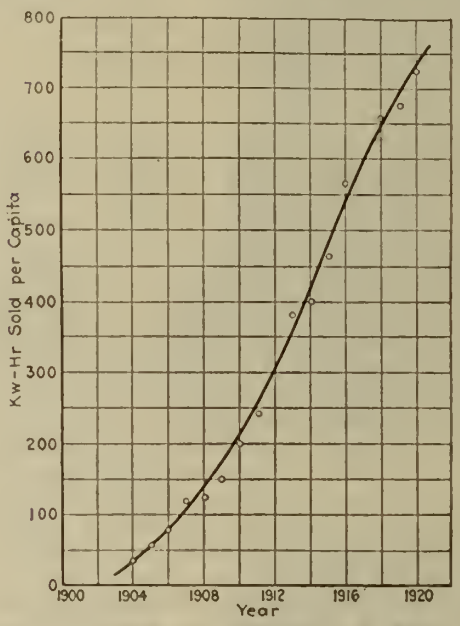

Fig. 1.—Increase in Consumption of Electric Power in Detroit Between 1903 and 1920.

stations are using, or are being constructed to use, a pressure of from 300 to 350 lb. per sq. in. The curve of Fig. 3 shows that saturated steam at such pressures has a temperature well below 450 deg. Fahr. If we assume it will be possible to utilize pressure as high as, say, 500 lb. per sq. in. in the near future, we will reach a saturation temperature only a little higher than 450 deg. Fahr. To attain steam with a saturation temperature of 600 deg. we should have to utilize a pressure of almost 1,600 lb.

It is quite obvious that if we are to operate with the highest permissible temperature we must use superheated steam, even if we increase the maximum pressure to the highest imaginable limit. The curves of Fig. 4 are presented to indicate the theoretical possibilities of higher pressures.

It will be observed that the theoretical efficiency of the cycle increases with increasing pressure for both saturated and superheated steam. It will also be observed that at the temperatures to which we seem to be restricted the gain resulting from increasing the pressure from 200 lb. per sq. in. to 300 lb. is greater than for the next 100-lb. increase, and so on up to the highest pressures shown. Moreover, the maximum efficiency shown is not so much higher than the indicated for pressures and temperatures now in use that radical increase of pressure and temperature holds great promise.

A modern plant with steam pressure between 200 and 225 lb. and with a steam temperature of about 600 to 650 deg. Fahr. can produce power at a cost of about 19,000 B. t. u. in fuel per net kilowatt-hour. If the same ratio between actual results and theoretical efficiency of cycle holds for higher pressures and temperatures, we should be able to produce a kilowatt-hour for about 17,500 B. t. u. with steam at 400 lb. and 700 deg. Fahr. Taking probable extreme limits and assuming 600 lb. and 800 deg. Fahr., the cost of a kilowatt-hour would be about 16,000 B. t. u.

Such figures are certainly worth striving for, but unfortunately they do not tell the whole story, First, the cost of equipment will certainly increase with pressure and, to a certain extent, with temperature. Increased thermal efficiency will therefore certainly be partly offset by increased capital charges. Second, the ratio of actual to theoretical turbine efficiency should decrease with increasing pressure, so that the thermal gain to be derived from high pressures must be discounted to a certain extent. Third, the increased boiler pressure means increased flue-gas temperatures and this must result in offsetting part of the calculated improvement. If this increased loss is prevented by the installation of a device like an economizer of air preheater, we have increased capital and operating charges to consider.

It is the author's opinion that it will be quite a while before we resort to pressures higher than 400 lb. and that fuel will have to cost much more than is probable for the immediate future, while capital must, if anything, cost less to justify exceeding such a value. Against this is to be set the fact that we are now using or preparing to use 250 lb. in this country and that in England they have already exceeded 400 lb.

Ferranti's Proposed Turbine Cycle—The Emmet Mercury Boiler

Many years ago S. Z. Ferranti suggested an interesting modification of the turbine cycle. He proposed to add heat during the early part of the expansion so as to maintain the steam at a constant temperature during that part of the cycle. Practical difficulties led to a modification which has to most people obscured the original suggestion. In the modified form the steam is permitted to expand in the same way as it is now customary, but is completely withdrawn from the turbine at different points, reheated, and returned to continue the expansion. In theory this cycle promises an improvement of about 10 per cent over the cycle now in use. If actually used in an operating plant it is probable that not over 5 to 6 per cent improve-

ment could be shown. Against this would be chargeable increased capital costs and increased operating complications.

It is rumored that this cycle in a simplified form is to be used in a new English plant now under construction: It has actually been used in experimental apparatus, and according to reports the results were satisfactory.

Another interesting suggestion emanates from W. L. R. Emmet. Many binary cycles have been proposed and thermal savings can be calculated for most of them, but the one suggested by Emmet seems to be the most promising. He proposes the use of mercury as one working substance and water as the other. The mercury is vaporized in a fuel fired boiler something like a steam boiler, is expanded in a small turbine and condensed in a device which may be called a condenser-boiler. This device

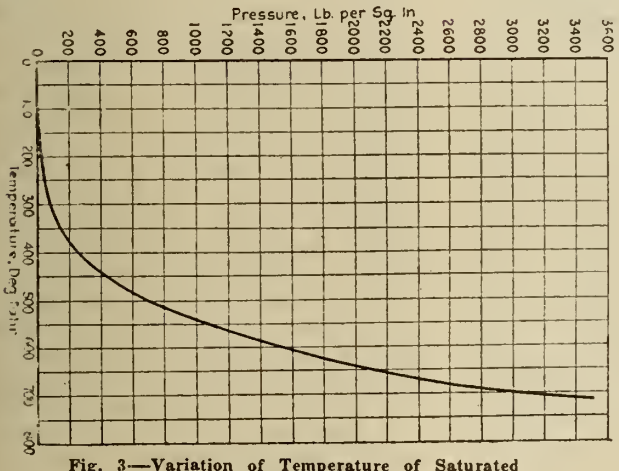

Fig. 3—Variation of Temperature of Saturated Steam With Pressure.

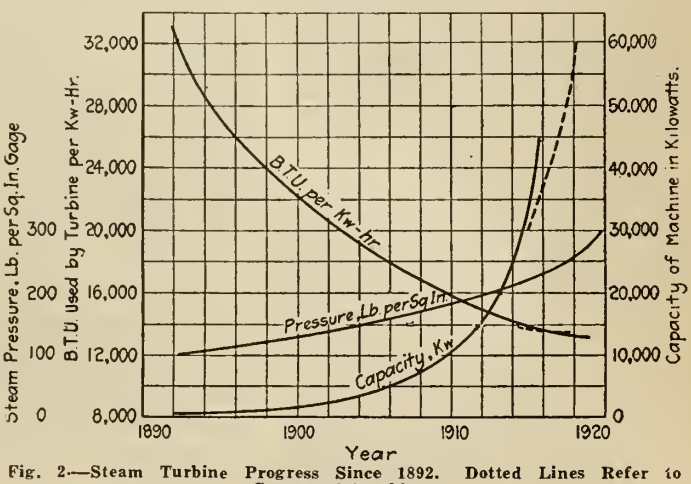

Fig. 2—Steam Turbine Progress Since 1892. Dotted Lines Refer to Compound Machines.

transmits the latent heat of vaporization of the mercury vapor to the water, converting it into steam which is used in a turbine in the ordinary way. Mercury boils at 677 deg. fahr. under atmospheric pressure and at 457 deg. under a pressure of 2 in of mercury. It thus is ideally fitted to extend the upper temperature limit without introducing prohibitive pressures. It also has such other physical characteristics that a comparatively cheap turbine can be used.

This proposal of Mr. Emmet's is by all odds the most promising of the binary types and it seems to be the only one that warrants serious consideration at the present time. It promises a return of about 40 per cent more power from a given quantity of fuel, and this without a prohibitive increase in investment.

Results Effected by Employment of Mechanical Stokers

Turning now from a consideration of the turbine room to the boiler room, the introduction of the efficient and flexible mechanical stoker has reacted in two different ways. It has made it possible to obtain much higher boiler-room efficiency day in and day out, month after month, and is has made it possible to drive boilers at much higher ratings than were even dreamed of a comparatively short time ago. Increasing the quantity of steam which can be produced from a given equipment naturally reduces the overhead charges per unit of steam output.

Now the power producer does not care whether his power becomes cheaper because of more efficient use of fuel or because of more efficient use of capital. Consequently there is evident an increasing tendency to overstoker boilers and to drive them at high average rates. This is quite proper if it is not carried too far. Unfortunately the thermal efficiency of boiler units decreases with increasing output above a certain point, and if the rate of evaporation is carried far enough a point is reached at which decreased thermal efficiency and increased maintenance more than balance the savings in capital. The point at which this occurs differs with the character of equipment, the price of capital, the price of coal, the load factor and other considerations, but under average central-station conditions the most economical point will generally be found below 200 per cent of normal rating if economizers are not used. The addition of economizers naturally raises the proper value. It is probable that the cost of capital and apparatus will ultimately come down to pre-war figures or very nearly to such figures, and it is equally probable that the cost of fuel will not. Under such circumstances the economic balance will probably be found to occur at a lower average rate of evaporation than some designers have expected.

Economizer Problems

One of the principal losses occurring with high boiler ratings results from high flue-gas temperature. This loss can be partly recovered by the use of economizers. However, economizers cost money to install, money to maintain and money to operate, and the waste is not therefore entirely recoverable. Some designers of power plants appear to give inadequate weight to some of the costs incurred in the practical operation of economizers.

It is rather interesting to note in passing that despite the increase in the price of coal during the past six years, the situation with respect to the installation of economizers has not materially changed. The author knows of cases in which quotations on economizers increased during the same period at such a rapid rate that despite the increasing cost of coal the installation of economizers could not be justified. This is probably a transient situation; the cost of economizers may be expected to drop to a point which will place them in a much more advantageous position than that occupied before the war.

But here we are faced with another complication. Economizers until quite recently were made of cast iron exclusively. As the steam pressure in use has risen more and more, engineers have begun to question the propriety of using cast iron for such apparatus. It seems certain that all will agree that if we adopt pressures like those we are now considering, cast iron will be ruled out unless we operate economizers at a pressure much below the boiler pressure. This introduces undesirable complications.

Such considerations have led to the construction and use of wrought-steel economizers. These can be built with factors of safety equal to those used in boiler construction; they are practically as satisfactory as cast iron with respect to corrosion on the gas side, but are much more apt to corrode on the water side. In fact, it is possible to cause failure of steel economizer tubes by corrosion on the water side within a year.

In modern plants such corrosion is generally due to dissolved oxygen and can be prevented if proper precautions are taken to keep the boiler feed sufficiently free of this gas. There are now several well-recognized methods of doing this.

Air Preheaters

Within the past few years another device has been introduced for conserving heat otherwise lost in flue gases. This is the air preheater. Air used for combustion must be heated to furnace temperature from the temperature with which it enters the furnace. Ordinarily this is done in the furnace at the expense of heat liberated by the fuel. That

part of this heat which is required to raise the temperature to a value equal to that with which the flue gases leave the boiler is wasted through the boiler damper.

If a large fraction of this heat could be conserved by transferring it from flue gases to entering air by means of an air preheater, a fuel saving of 10 per cent or more could be made. It does not seem probable that any such complete transfer can be effected in a real case, but some fraction of it is certainly attainable. It appears as though a saving of 3 to 5 per cent might prove possible.

However, this device also introduces problems of its own. It can be built comparatively cheaply, but its use involves additional flues and fans and power for driving the fans, so that the gross thermal gain in any case will be partly offset by increased thermal expenditure and increased capital charges. Further, it seems certain that air preheaters will present new cleaning and maintenance problems which will also yield items of expense which must be balanced against the gross thermal saving.

In addition to all these considerations we have another which may prove of still greater importance. We do not yet know the limiting temperature to which it is permissible to raise the air. The air supplied for burning fuel on the grate or stoker passes through that device and serves to cool it by removing heat which is radiated and conducted to it. It is certain that we can use air temperatures higher than those now common, but whether we will find 150 deg. Fahr. or 300 deg. or 500 deg. to be the upper limit, is still unknown. The author is inclined to think that the upper limit will vary with the type of stoker and it is obvious that is will vary with the rate of combustion.

Feedwater Heating

Great improvements have been made in the character of boiler feedwater used in the large plants of the country in the past decade. In the early days we used for boiler feed or make-up water anything which was readily attainable. If the scale deposited in the boiler was of such character as to cause too much trouble, we treated the water chemically before use. But we still concentrated a chemical solution in our boilers, had to blow down at frequent intervals and were forced to shut down and thoroughly clean them periodically.

We have now greatly improved this practice in the case of plants using surface condensers. In such plants the greater bulk of the water evaporated in the boiler is used over and over, being contained in what one might call a practically closed circuit. There is a certain loss from leakage, blowdown, spillage, etc., but this can be kept down to a value between 1 and 2 per cent of the total boiler feed by careful management. The make-up required to make good this loss is now commonly distilled and enters the system as a vapor, leaving dissolved salts behind in the evaporator.

With a plant operated in this way there is practically no deposit in the boiler. As a result blowdown losses are practically eliminated. Of still greater importance, however, is the fact that the expense of shutting down, opening up the boiler and turbining the tubes is almost completely done away with. In this case the improvement results not so much in a thermal gain as in decreased labor and maintenance charges and better use of invested capital.

Much thought has also been given recently to different methods of obtaining auxiliary power and to different methods of heating the feedwater. These

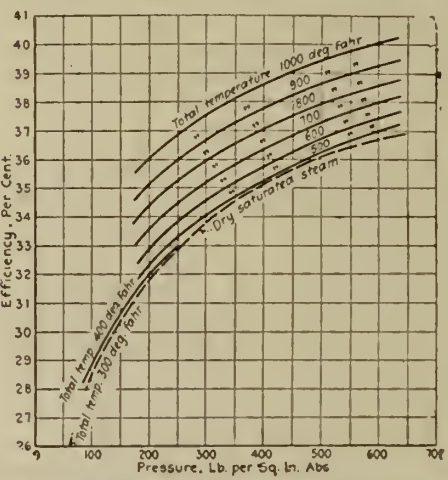

Fig. 4.—Efficiency of Complete Expansion Cycle as Used in Steam Turbines (Back Pressure in L9)

factors are closely tied to the use of economizers and air preheaters, and that method which is best under one set of conditions is not necessarily usable with a different type of plant.

We seem to be settling down to two different types, although the whole subject is as yet admittedly in a state of flux. In the one type steam-driven house generators are used to supply some or all of the auxiliary power. The steam exhausted heats the feedwater in heater-condensers operating at such a vacuum as to give a feedwater temperature sufficiently low for advantageous use in economizers. In the other type the feedwater is heated by steam drawn from the main unit. This heating is preferably done in stages, and if the idea is carried to the limit, it results in the introduction of a cycle which is theoretically more efficient than the simple, so-called Rankine cycle now in use. Unfortunately, if this arrangement is carried to the ultimate limit it yields feedwater with a temperature higher than can be used advantageously in economizers. It also has another disadvantage from the view-point of the central station. Auxiliary power must logically be taken from the main bus and continuity of service is correspondingly jeopardized.

Utilization of Low-Grade Fuels

No consideration of the evolution of power plants would be complete without a reference to the work which is being done in an effort to make available for use the poorer grades of fuel. Stokers are continuously under development and we are already obtaining very promising results with fuels which only a few years ago were practically unusable. Further, many attempts are being made to introduce pulverized fuel into central-station boiler rooms, and one large new plant is being completely equipped for the use of such material. Much is promised by the pulverized-fuel advocates in the way of increased thermal efficiency, decreased labor charges, and ability to use poorer grades of coal. As yet the case is not proved, but the experience of the next five years should bring out the facts. Personally, the author believes that the preparation of the fuel for the burner must be greatly simplified and cheapened before pulverized coal can compete with good stokers under central-stations conditions in most sections of the country, but it must be confessed that many engineers in the industry do not share in this view.

So much for the trend of the times in power-plant design. It will now be of interest to attempt to evaluate all the possible improvements in sight.

Future Possibilities in Plant Efficiencies

If we assume that we will continue to use steam turbines and other equipment of the present types, but that we will increase pressure and temperature to the limit and will introduce all possible heat-saving devices, we can lay down on paper a plant which should deliver a net kilowatt-hour for between 14,000 and 15,000 thermal units. This would correspond to overall thermal efficiencies of the order of 24 or 23 per cent. Our best plants of the present day give values of 18 to 19 per cent.

The author is certain that with the fuel prices which are to be expected in this country in the immediate future, such thermally efficient plants would not represent the best engineering or economic solution of the problem. The investment would in his opinion be higher than could be justified. On the other hand, he does expect to see a figure between 16,000 and 17,000 attained in the very near future.

NEW INSTALLATIONS

The town of Barrie, Ont., has installed a 225 horse power Sterling Engine and a De Lavel pump of 1,500 gallon per minute capacity to replace the present steam equipment.

Mr. J. H. Bennett, Power and Light Commissioner of the town, also informed Power House that they will install a 500 gallon De Lavel electrically driven centrifugal pump to supplement the present electrical equipment. The present equipment (steam) will be disposed of, and a list of this equipment will be found in the advertising columns in the near future.

Overhauling and Adjusting in the Engine Room

In this Article the Author Has Something to Say About that Much Abused Article, the Steam Trap. He Mentions the Principal Types, and Seems to Think that Their Usefulness Depends on the Kind of Care They Get

By "FITTER."

THERE is perhaps no one source of loss that does greater damage to the fuel consumption than leaky and inefficient steam traps on steam and return mains. An open ended pipe is not such a serious source of loss as a pipe with an inefficient trap on the end of it. In the first case the loss is seen, and will be choked down as much as possible, but a trap that is continually blowing steam through, instead of trapping it, is a source of unseen loss that may mount into big figures. The necessity of continual care of these appliances is therefore obvious.

Various Types of Traps

The variety of traps is almost infinite, and there always seems to be a sample of half a dozen different kinds in every steam plant, the larger the plant, the more types of traps being the general rule. This is due to the indiscriminate purchase of traps without considering the special duty they have to perform, and also to the fact that a good many engineers will purchase a new trap rather than try and make the ones they have work properly. Of necessity, traps are often situated in places where they are hard to get at, and the temptation is to leave them severely alone, and in some cases to put on an additional trap further along the line where it can be seen. Systematic examination and adjustment of traps is the only possible way to obtain satisfaction. Almost every trap on the market will perform its duty if given a chance, although this does not mean that some traps are not better designed than others. The trouble with almost every kind of trap is that it demands a great deal of attention, and in a plant where there are none too many hands to look after the various pieces of apparatus, the trap is liable to be neglected.

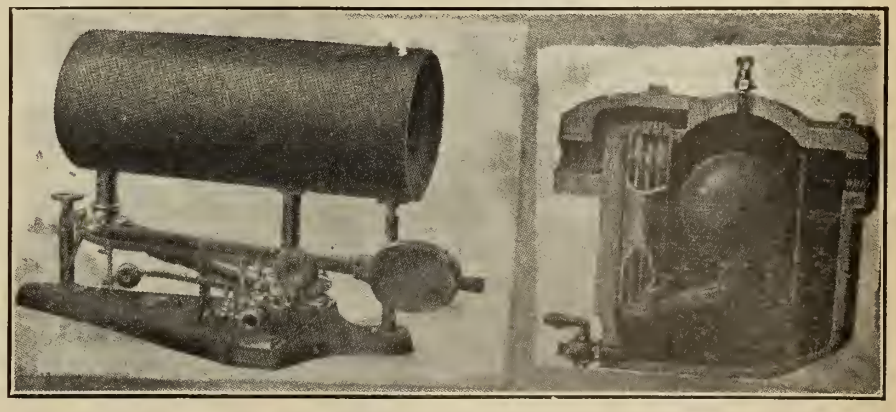
Considering first of all the traps that are purely for separating or draining purposes, that is traps that merely discharge the water collected to a hot well or to the drain, we usually find the ball float trap with needle valves controlling the discharge. Now there is not a great deal to keep in order on such a trap, but on the other hand, they are very quick to get out of order if neglected. There are generally in this type of trap a copper ball float, which is attached to a lever, a fulcrum point for this lever, and a fork joint at the end of the lever where the valve rods are fastened on. The valves themselves are of the needle point type, and are usually fitted at the bottom of the trap, although in some cases they are inverted and placed at the top of the trap. The possibilities of trouble in this type of trap are of a definite nature, easily watched. First of all the ball float may collapse, or become perforated, with the result that the trap will not operate at all. The various joints may become worn, so that it takes a much larger movement of the ball to produce the necessary valve opening. Thirdly, and by far the most frequent source of trouble, is the valve or valves being held open by small pieces of scale or dirt getting between them and their seats. This speedily results in cutting of the valves and their seats, and a continual leakage results. This type of trap should be examined at least once a month, if it is at all possible. Such traps are used on such positions as the drains from receiver coils on compound engines, where the steam coming to them may be oily, and the water only fit for discharge, cylinder drain cocks for the same reason, or in isolated places where it is not convenient to return the water to the hot well or heater. As a rule it is quite easy to see if these traps are functioning properly by having an opening fitted with a valve tapped onto the discharge pipe, in plain view. It is then only necessary to open this valve cock, and watch this operation for a few minutes. If a continuous feather of steam is noticed coming from the opening there is no doubt but that the trap is blowing steam through. If it is working properly, then a definite discharge of water for a period, followed by a period of no discharge, is observed. The temperature of the discharge pipe is a guide in some cases, though this is not a very good thing to go by, especially if the trap is on a high pressure line. Any trap that is discharging to a sewer or hot well, or better any trap that has an open discharge should be arranged so that the discharge pipe can be seen at any minute. The amount of steam that can be lost can be very easily calculated. The well known Napier's rule says that for steam over 60 lb. gross pressure, the weight of steam that can be discharged through orifice of one square inch, is in 70 seconds exactly equal to the gross pressure. Let us see what this means in figures. Suppose we have steam of 100 lb. gauge, or 115 lb. gross pressure per square inch, discharging into a one inch steam trap which is leaking, or allowing the steam to blow through. The probable amount of opening may easily be one half the area of the discharge. that is it would be equal to one quarter of a square inch. Now the rule in formula form is W or weight of steam is equal to

$$\frac{P \times A}{70}$$

lbs per second, where P is the gross pressure and A is the area of orifice. Substituting figures in the formula we have

$$\frac{115 \times .25}{70}$$

which gives .41 lb. per second, or 25 lb. per minute, 15,000 lb. per hour, or 36,000 lb. per day of 24 hours. If a pound of coal is evaporating 9 lb. of water, in 24 hours we can lose 4,000 lb. of coal through a leak of this kind. Did trap leakage ever occur to you in this particular way before? If not, it is easy to realise how a few little leaks on even ½ inch traps, can make themselves felt. Of course in a plant containing only one boiler, with a grate area of say 30 square feet, and a consumption of 12 lb. coal per square foot grate surface per hour for ten hours a day, say 3,600 lb. per 10 hours, and 400 lb. over the night period of banking, such a loss would cause instant action. Suppose instead, you have a plant con-



Tilting Trap and Ball Float Trap.

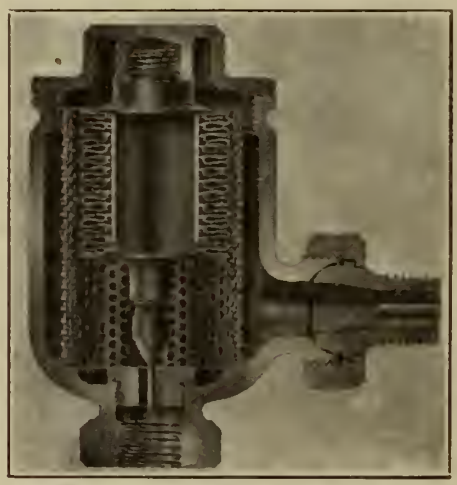
taining six boilers, with a grate surface of 30 square feet each boiler, and forced draught, burning 25 lb. coal per foot grate surface per hour, and running 24 hours. The normal consumption would be then 108,000 lb. per day. If it rose gradually to 112,000 lb. it would not be so easy to locate the trouble. Suppose in this same plant there are a dozen or more of these traps distributed around and there is a very small leak in three or four of them what will happen to the consumption?

Volatile Liquid Traps

Traps largely in use nowadays, especially on heating systems, for radiator purposes, are of the type that are operated by the expansion and contraction of a diaphragm containing a volatile liquid which is very quick to answer to changes in temperature. This liquid may be mercury, or some such substance, which has a definite and appreciable expansion per degree of temperature. The valve is fastened to the diaphragm, and is so arranged that when the liquid is heated up to the temperature of the steam which it is to control, that the valve will be pressed hard against the seat by the expansion of the liquid in the diaphragm. When this steam condenses, the liquid contracts, and the diaphragm closes together like a concertina, thus lifting the valve away from its seat. There is practically only one trouble likely to happen to this type of trap, and that is dirt getting on the seat and holding the valve open. They are usually constructed in such a way that there are no pockets around the seat to hold any obstruction, and the rush of water when the valve opens usually cleans off the seat. However, there is always a possibility of such a thing occurring, and it is well to have a look at these traps occasionally to make sure that everything is as it should be. If the engineer who is just starting up will only get into the way of systematically examining things whether they need it or not, he will save a lot of trouble for himself, for after all it is only by opening things up that he can find out how much they do need. Of course this thing can be carried to excess, but so can the habit of not examining things. We remember an old chief we sailed with some years ago, who used to say "She was all recht when she came in, and if you leave her alone, she will be all recht when she goes out." This reasoning had stood him in good stead for a good many years but it finally proved his undoing for on one voyage his low pressure piston fell to pieces on him when a few days out. There is a happy medium, and a man soon gets to know which parts of his particular plant need the most attention.

Tilting Traps

The return tilting trap is now in almost general use in power plant practice, and while there are a number of different makes, the general principle is the same. They consist essentially of a receiving drum, mounted on trunnions, that permit it to tilt up and down. The pipes leading into and away from the trap, are on the same line, and two check valves are employed to govern inlet and outlet. The trap when empty is usually in a horizontal position, and the water is led into the trap through the trunnion, the check valve opening to allow the water to come in. While this is going on, the discharge check valve is held shut by the boiler pressure acting against it. When the trap is filled with water, the weight causes it to tilt on its fulcrum, and as it does so, it opens automatically a valve which admits live steam onto the top of the water in the trap through the other side of the trunnion. This live steam pressure together with the weight of



Typical Trap of the Volatile Liquid Variety.

the water in the trap which is set some distance above the water level in the boiler, closes the check on the inlet pipe, and opens that on the discharge pipe against the boiler pressure, discharging the water into the boiler. When the trap is empty, a pivoted weight brings it back to the horizontal again, closing the steam valve at the same time.

The principle is simple, but unfortunately these traps have been the cause of great dissatisfaction to a good many, chiefly it is to be admitted, not through any fault of the traps, but for pure want of care and attention. Practically every trap has one weak point, and that is the trunnion. This part has a very hard duty to perform, and unless it is kept carefully packed, well lubricated, and evenly adjusted, it will leak badly, or else cause the trap to stick in one position or the other. When this sticking occurs, it is often the practice to interfere with the adjustment of the counter weight or weights, thus causing more complications, for every time the packing is adjusted the weight will also have to be adjusted. Uneven tightening up of the trunnion glands will cause sticking, while even tightening up if too much is given will cause the same thing. Return traps being situated on top of the boilers, are not in a position that tempts anyone to stay too long in their company, and the usual result is that when one gives a little trouble, which cannot be remedied right away, that the easiest way out is taken and the whole thing condemned. We wonder how many idle tilting traps there are in the Province of Ontario alone, representing money spent to no purpose, and each one a slur on the manufacturer, who is innocent. Although the steam valve gives trouble sometimes, due to the hard service it gets, the chief cause has been in our experience in the trunnion. We expect that every trap manufacturer will say that this is the case in all the other traps, not in his. However, if the trunnions are carefully and intelligently adjusted, and well looked after they will behave as well as most of the other special apparatus in the plant. Remember a machine of any kind is just a machine, and none of them can function without intelligent human care. Surely there should be no place where machinery could get more highly skilled attention than in a modern power house.

OTTAWA LODGE AGAIN

The Ottawa Lodge of the C.A.S.E. held another of their famous open meetings on Thursday Sept 22nd, in the hall of the Department of Trade and Commerce. As is usual when Ottawa Lodge holds an open meeting a large attendance of engineers and others turned up.

The lecture for the evening was delivered by Mr. Dickey of the C.Q. Dunham Co. of Toronto, and was illustrated by lantern slides. Mr. Dickey was very much at home in his subject, "Heating," and showed both how and how not to tackle the question of successfully heating a building. Besides the slides there were a couple of moving pictures, which were highly appreciated by all.

It is the experience of Ottawa Lodge that after every one of these open meetings there are quite a number of applications for membership. In fact so pronounced is this feature, that the members are alluding to the open meetings as revival meetings, so many come forward to remedy their past mistake of not being members of the C.A.S.E.

HAMILTON LODGE C. A. S. E.

At a recent meeting of the Hamilton Lodge, a lecture on the Jones Underfeed Stoker was given by the Executive Secretary Mr. L. J. Ellis, the slides being kindly loaned by the Under-Feed Stoker Co., of Canada. Brother A Bramham the president of the lodge, also assisted in the lecture, he being very conversant with the operation of the stoker, The Standard Underground Cable Co's plant, of which he is in charge, being equipped with them. A hearty vote of thanks was given to the Underfeed Stoker Co. for their courtesy in lending the films.

Some Notes on Magnetic Leakage

By TERRIL CROFT

(Copyright.—All Rights Reserved.)

THERE is no known insulator for magnetism (lines of force). In dealing with electric currents we can direct them definitely by using conductors where we wish the current to flow and by interposing extremely poor conductors or insulators to prevent the electricity from flowing where we do not desire it. Fortunately, air is a splendid insulator of electricity. Unfortunately, in this respect, there is no very poor conductor or insulator for magnetism. Air is a fairly good conductor of magnetism, although it is not nearly as good as iron.

It follows then, that, even if an iron core has developed in it a flux of lines of force, there is likely to be some *leakage* of these lines through the surrounding air because the air has fairly low reluctance. An iron magnetic circuit surrounded by air is analogous to an uninsulated-copper electric circuit immersed in impure water. There would be some leakage of the electric current of such a circuit through the water just as there is some leakage of magnetic flux through the air. Because of this leakage all of the lines developed by the m.m.f. of a helix cannot always be confined to the iron of a magnetic circuit.

An example of magnetic leakage is shown in Fig. 1. A certain current is flowing around the helicies on the magnetic cores and produces a flux around the magnetic circuit. This picture indicates the principle of magnetic leakage but the values given are only illustrative and must not be taken as accurate or absolute—

Example.—At 1 the armature is held tightly against the poles, there is practically no leakage and a total flux of 9 lines circulates around the entire magnetic circuit. If the armature is pulled a short distance away from the poles, as at 11, the reluctance of the circuit is increased which decreases the flux to 7 lines and there is some leakage. As the armature is pulled further away, as at 111, the reluctance is still further increased reducing the flux to 6 lines and there is considerable leakage. If the armature is now entirely removed the reluctance of the magnetic circuit is very greatly increased because of the very large air gap, the total flux is thereby reduced to 5 lines and there is a great amount of leakage.

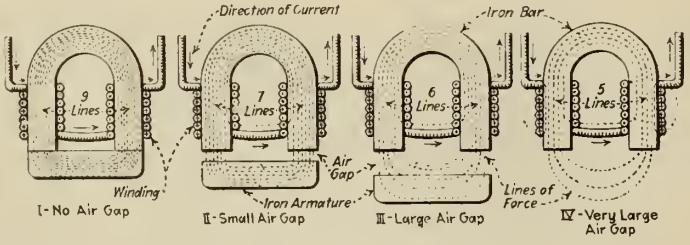


Fig. 1.—Illustrating Magnetic Leakage.

Examples of leakage lines in generators and motors are shown in Fig. 2.

Magnetic leakage can be practically eliminated by distributing the winding which develops the magnetomotive force uniformly around the magnetic circuit (Fig. 3,) this applies only where the reluctance is uniform along the entire length of the magnetic circuit. If the reluctance of certain portions of a circuit is different from that of other portions, the winding should be distributed along the portions of the circuit, each portion being provided with a part of the winding in proportion to its reluctance. That is, the portions of the circuit that have the greatest reluctances should have the greatest proportion of the amp. turns. The portions of the circuit that have little reluctance should be provided with correspondingly few amp. turns. In practice it is seldom possible to distribute a winding over the parts of a magnetic circuit in proportion to their reluctances but it should be done insofar as practicable.

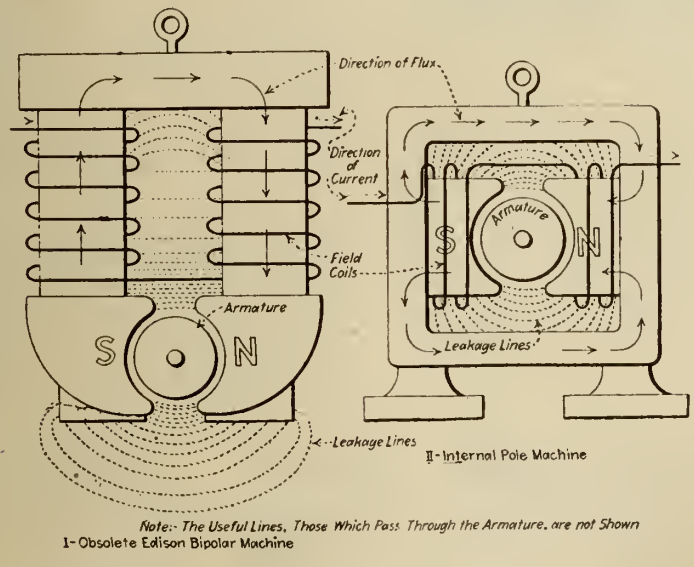

Fig. 2.—Leakage Lines of Generators and Motors.

Example.—Why it is that distributing the winding eliminates leakage will be evident from a study of Figs. 3 and 4 which show analogous electric and magnetic circuits. The electric circuits are immersed in a tank of water with a little acid in it, which renders the water conducting to electric currents. This is analogous to the usual condition of magnetic circuits which are always surrounded by air or by some other medium that is a fairly good conductor of magnetic flux. Now if the source of e.m.f. is concentrated as at 1 (Fig. 4), the maximum voltage developed, 8 volts in the case shown, is impressed across the copper electric circuit and the conducting liquid in parallel. The current due to this 8 volts will divide between the water and the copper paths in inverse proportion to their resistances in accordance with the law of divided circuits. Much more current will flow through the copper than through the water because the copper has, probably, much the lower resistance. However, some *leakage current* will flow through water as shown.

Current will flow through the water from locations in the copper ring of 1 which are at a high potential to those of a lower potential, as shown. The current that flows between any two locations will be proportional to the difference of potential—voltage—between the two locations. Evidently then the most current will flow through the water from one end of the copper ring to the other, at the points where the battery joins the ring and where the difference of potential is 8 volts. Obviously, if it were possible to so arrange

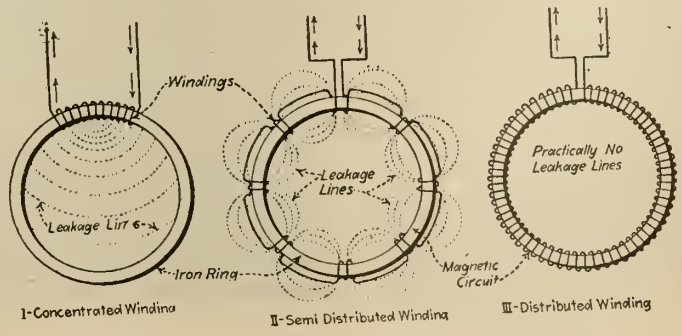

Fig. 3.—Leakage From Magnetic Circuit Surrounded by Air.

his submerged electric circuit that all locations in it would be at the same potential there would be no leakage currents through the water.

If the 8 cells are arranged around the circuit, as at Fig 8 11, the greatest possible difference of potential is 1 volt and the leakage currents are correspondingly reduced. However, by Ohm's law the same current is flowing through the copper conductor in 1 as in 11 because the total voltage impressed on the circuit is the same in both cases and the resistance is the same. Now if, as in 111, 16, 1-2 volt cells are uniformly arranged around the submerged electric circuit, the maximum difference of potential is reduced to 1-2 volt and the leakage currents are therefore practically eliminated nearly all the current will flow through the copper conductor. It is conceivable that a still greater number of cells, of correspondingly lower voltage, could be cut into the circuit and the maximum potential difference between any two locations in the circuit might thereby be reduced to practically O (zero) in which case of course, there could be no leakage currents through the water. In other words, if the cells that produce the e.m.f. were uniformly distributed around the electric circuit there could be no leakage currents.

A similar set of conditions obtains with the analogous magnetic circuit of Fig. 3. With the amp. turns concentrated as at 1 a large difference of magnetic potential form.m.f. is concentrated across the ends of the winding and there would be a correspond ingly great leakage. With the winding semi-distributed as at 11 the maximum possible difference of magnetic potential is reduced and the magnetic leakage is decreased accordingly, just as the maximum difference of electric potential was reduced in Fig. 4, 11. Now with a winding uniformly distributed as in 111, all parts of the magnetic circuit are at practically the same magnetic potential and there can be no magnetic leakage.

Therefore, where possible, the winding for developing a m.m.f. in a magnetic circuit should be so distributed that the m.m.f. will be consumed in that portion of the circuit where it is applied. Then there can be no leakage. Even with an air core, when a helix winding is uniformly distributed as in Fig. 5. 1, there is no appreciable leakage.

The computation of magnetic leakage is complicated and almost impossible in many cases because of the difficulty of determining the area of the path, of the magnetic circuit in air, that the leakage lines traverse. The lines spread out in passing through the air and how great or how small is the cross sectional area that they actually occupy cannot be readily estimated or calculated.

In practice, leakage is usually determined experimentally. A magnetic circuit having been built, its lekage or *leakage factor* can be ascertained by electrical and magnetic measurements.

The leakage factor of a magnetic circuit is the value by which the number of *useful* lines of force must be multiplied to ascertain the number of lines of force that must be developed by the amp. turns of the developing helix. That is, the leakage factor of a magnetic circuit is equal to the number of lines developed in the circuit divided by the number of useful lines of the circuit.

Example.— If, in the magnetic circuit of Fig 2. 1, it is necessary to design the field magnet coils to produce 140 lines of force for every 100 lines that are useful, that is, that pass through the armature, the leakage factor of that magnetic circuit is 1.4.

Leakage factor values vary with the arrangement and characteristics of a magnetic circuit. As a general proposition, the greater the pole piece surface exposed to the air the greater will be the leakage; see the illustration of Fig 6. In commercial generators and motors the leakage factor of the magnetic circuit may vary from 1.1 to 1.5. With modern machines, is probably varies between 1.1 and 1.3. Fig. 6 indicates approximate leakage factort for some typical magnetic circuits.

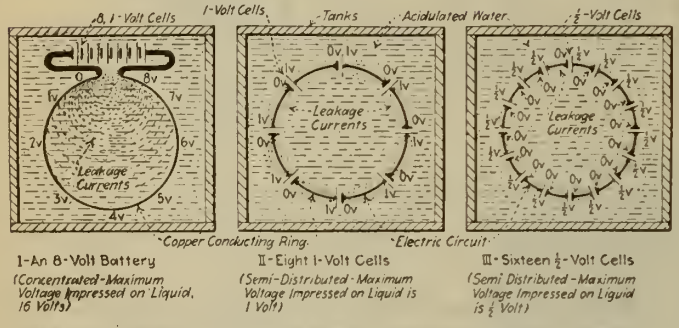

Fig. 4.—Leakage From a Magnetic Circuit Surrounded by Water.

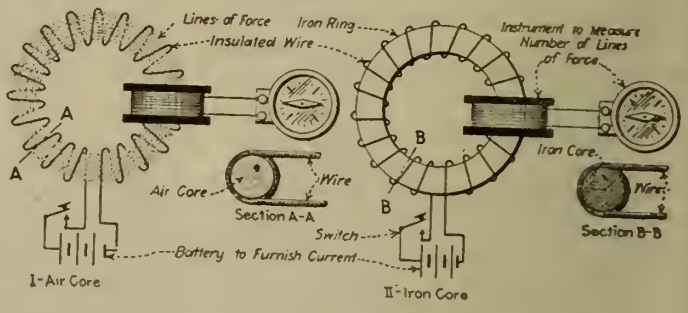

Fig. 5.—Arrangement for Determining Permeability of Iron.

In Power House of Sept 5 is an article describing an alleged boiler collapse and stating that an opportunity is provided for some readers to do a little thinking. I don't see why all readers should not do a little thinking or even much thinking, but no doubt the editor has reasons for placing the limitations.

In my opinion the drawing in of the head would be a perfectly natural result of a bag of the dimension and location of the one in question and would be due to the tension caused by the forming of the bag, and I don't see how any body but the owner of the boiler could call such a deformation a collapse R. McLaren.

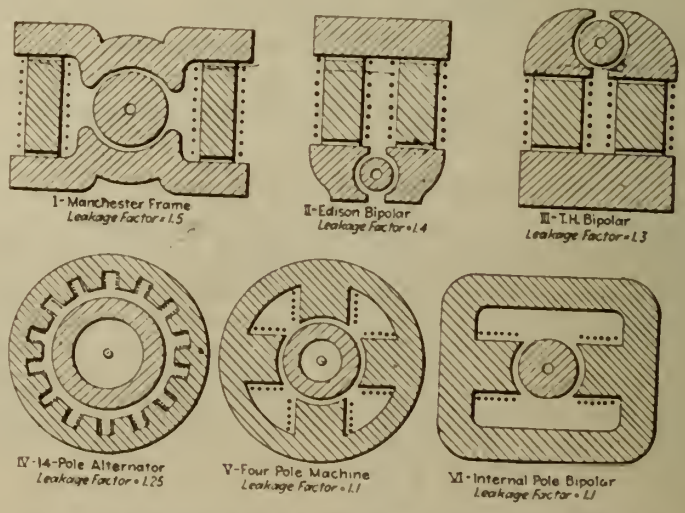

Fig. 6.—Leakage Factors of Magnetic Circuits of Electrical Machines.

Woodburn's Limited have been appointed sole Canadian representatives for a new electric resistance wire, which is being marketed among leading manufacturers of electrical appliances. Wiggam & Co., of Birmingham, are the manufacturers, and claim this was used for years in the British army.

Central Plant of the Acadia Coal Co.

The Boiler Plant and Boilers—Coal Handling at Power Plant—The Turbo Generators — Switchboards — Busbar Room — The Operation—As Seen by "Power House" Special Representative

J. A. McGILLIVRAY

THIS plant is one of the best equipped Colliery Power Plants in Nova Scotia. Built in 1911 with additions and improvements made in recent years, today represents an expenditure, for the Central Power Plant alone, of over $500,000.

With the installation of the power plant practically all the steam driven units at the Company's mines were replaced by electric drives. New bankheads were erected entirely of steel, replacing the old wooden structures. Fans, pumps, compressors, and hoists as well as bankhead equipment are now electric driven from central power plant, with one exception—the Allan shaft hoist, which is steam driven.

The following mines are served from the central station—Albion, MacGregor, Allan in Stellarton, and The Vale Colliery at Thorburn eight miles distant.

The Station generates at 3150 volts and this is stepped up to 13000 V for transmission to Thorburn Colliery.

Boiler Plant

The boiler room is built of brick with concrete foundation and concrete floors. The size of the building is 130 ft. x 78 ft. x 45 ft high to the eaves. The thickness of the walls being 20 in.

The foundations of the boilers extend from solid ground to the turbine floor. The flue or smoke box is constructed of concrete extending the full length of the building and terminating in a brick chimney. The chimney is built to a height of 140 feet above the grates and is 14 feet in diameter, constructed of brick, by the Custodis Company.

The Power Plant.

The boilers are arranged in five batteries of two boilers each, 10 in all, having a combined heating surface of 45,100 sq. ft. Six of the boilers are equipped with superheaters having a total superheating surface of 13,200 sq. ft. The boilers were furnished by the Babcock & Wilcox Company and are equipped with chain grate stokers—9 ft. wide by 12 ft. long, giving a grate surface of 108 sq. ft., or 41.8 sq. ft. of H.S. per sq. ft. of grate.

Steam is generated at a pressure of 150 lbs. per sq. in. though the boilers are built for a W.P. of 200 lbs. per sq. in. The amount of superheating is 207 deg. Fah. The superheaters have sufficient capacity to superheat to 300 deg. Fah., but it is found by experience in this plant that about 200 deg. Fah. is the most satisfactory as excessive superheat has been found to have a decided influence on the cost of upkeep.

The boiler feed pumps are located in a separate building adjacent to the boiler plant and consist of two standard Weir feed pumps, 13½ in. x 10 in. x 24in. stroke capacity each 85000 lbs. per hour against a 420 ft. head. One Lea Courtenay turbo feed pump, Terry turbine driven—this pump capacity is 159,360 lbs. per hour against a 420 ft. head and speed 2900 R.P.M. The steam consumption is 45 lbs. per B.H. P. Eff. 54%.

In this room is also located the feed water heater, Webster open type, capacity 4000 H.P. of water at 210 deg.

The condensed steam is metered at the heater by an Alburger Pump and Condenser Company's meter, having a capacity of 150,000 lbs. of water per hour. As the metering tanks dump they are recorded by a counter and also electrically recorded in the power house on a recording chart.

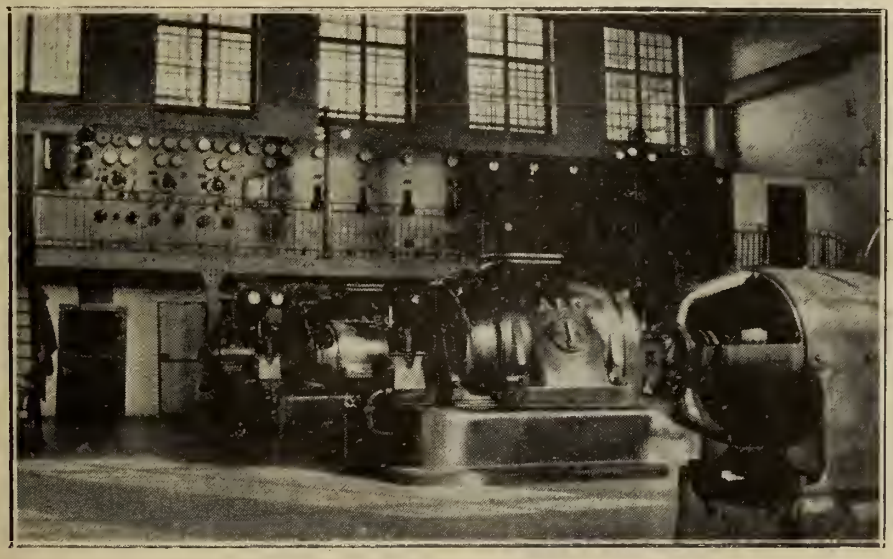
The supply of water to the boilers is made up of condensate from the condensers and the cooling water used on the turbines, additional made up from city mains when needed.

The feed water is heated by the exhaust from the auxiliaries, the average feed temperature being 93 deg. Cent. or 200 deg. Fah.

The water to boilers is measured by a Worthington hot water meter located in the feed line.

The boilers are fitted with recording draft gauges, Uehling automatic Co^2 graphic recorders and Uehling automatic hot gasses temperature recorders.

Coal is delivered by rail to private siding and dumped into a track hopper,



Direct Connected Exciters

from which it falls by gravity into a B. & W. tray conveyor delivering to a rotary automatic filler, which fills the buckets of the gravity bucket conveyor and is elevated over the bunkers. There is a coal crusher in the yard that crushes the coal into pieces not exceeding 2 in. cubes. (Normally low grade coal from the Company's mines is used for steam generation, the stokers and furnaces being adapted for low grade fuel.) The capacity of the coal handling apparatus is 40 tons per hour.

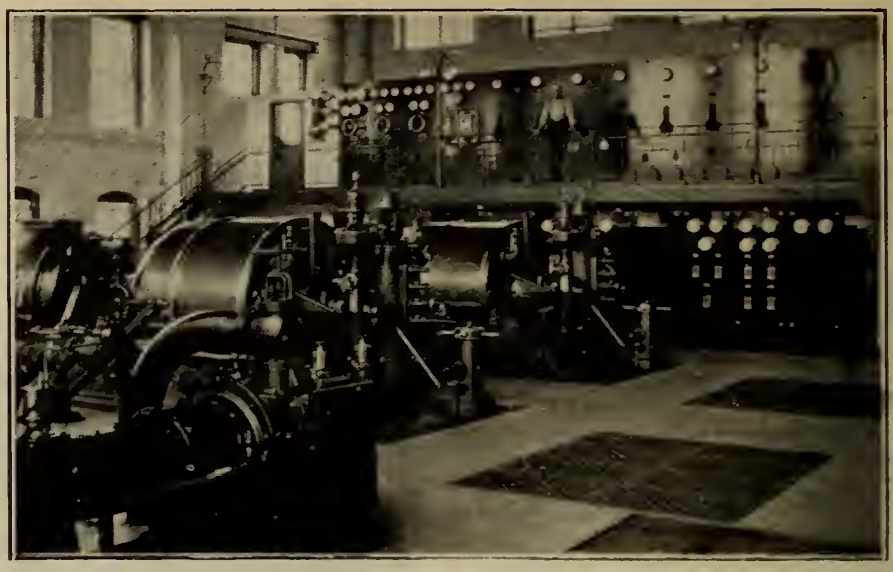
Ashes are flushed out by the overflow from the condensers into a valley.

The Turbo Generators

The turbines are located in a brick building 78 ft. x 62 ft. x 45 ft. high, separated from the boiler room by a brick wall. The building contains 3 turbo generators and their auxiliaries, one H. T. switch board, two L. T. switch boards, one air washer and humidifier, one 12 ton overhead "Miles" crane. The turbines are numbered 1, 2, and 3, and will be described in order.

No. 1. Built by the General Electric Company at Schenectady, N. Y., Curtis type having five pressure stages, capacity 5360 H.P. (4000 K.W.) speed R. P.M., steam pressure 150 lbs., gauge superheated to 207 deg. Fah. The full load steam consumption of this machine is 13.67 lbs. per K.W.H.at 150 lbs. per sq. in. (gauge) and 207 deg. Fah., half load 16.72 lbs. per K.W.H. The wheels are of nickel steel with special brass buckets, the first wheel having two rows of buckets. The diaphragms are cast iron with nickel steel nozzles.

There are three main bearings, the generator being coupled to the turbine by a solid coupling. The oil system contains 130 gals. of oil which is circulated through the bearings and governor under pressure as follows—thrust bearing 5 lbs. per sq. in., main bearing 25 lbs. per sq. in., governor 80 lbs. per sq. in. The normal temperature of the oil is 122 deg. Fah., at the receiving tank. The oil cooling system consists of a coil laid in the linings of the main bearings through which water is circulated. The packing glands on the main shaft



Generators and Switchboard

are of the labyrinth type, steam sealed.

The turbine is connected to the condenser by a multi-corrugated copper expansion joint. The condenser (a Worthington) placed directly below the turbine has a cooling surface of 7600 sq. ft. (1.9 sq. ft., per K.W.) The condenser tubes are of brass 18 B. W. G. with screwed ferrules on each end for packing. The water, both inlet and outlet, is 20 inch diameter. The atmosphere relief valve operates at 1 lb., back pressure.

The weight of the condenser when empty is 20 tons. The cooling water for condensing is supplied from the East River by motor driven centrifugal pump. A tunnel was driven from the East River to the power house, a distance of 780 ft. terminating in an under-ground pump-house, 34 feet below the power house basement. The water intake from the East River is 5 feet, 6 inches internal diameter.

In the underground pumphouse are located three centrifugal pumps to supply the turbines with condensing water. The delivery pipes are cross connected so that any condenser can be operated by any of the pumps. Provision is made to prevent flooding of the pump room at abnormally high tides. The overflow from the condensers is used for flushing the ashes from the ash pits. The ash channels are 18 inches deep and 36 inches wide, with a grade of 1½%. They are built of tile segments. The top of the channels are covered with wire screens of 2 inch mesh to prevent clinkers getting in before being broken up.

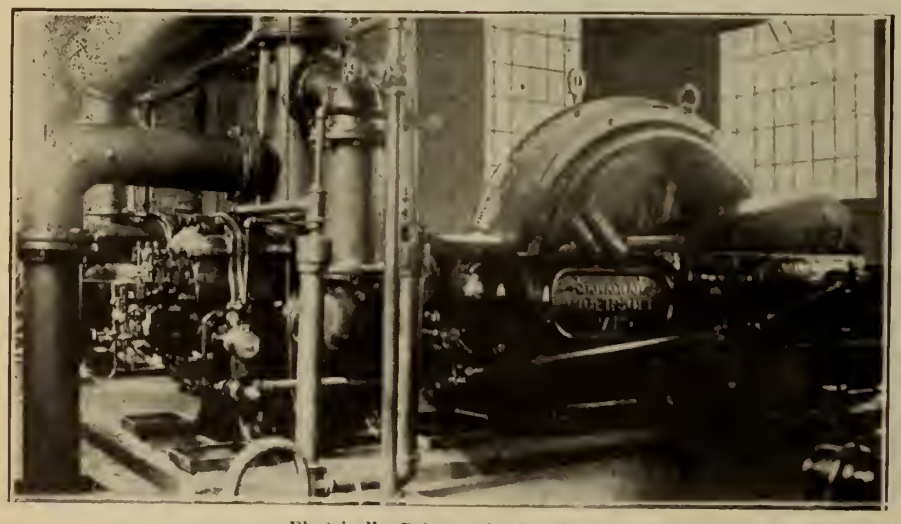
The condensate is pumped by a motor driven Worthington pump to the heater.

The dry vacuum pump is located on the turbine floor. The dimensions are 10 in. x 22 in. x 10 in. stroke and speed 100 R.P.M.

Turbines No. 2 and No. 3, differ in construction somewhat but operate under practically the same conditions as No. 1. Their capacity is 1875 K.V.A. each. They were built in Germany before the war, by A. E. G., Berlin. They are of the Curtis type, having nine pressure stages, besides the main admission valve which is controlled by the governor there are four auxiliary valves hand operated according to condition of load. They are of the four bearing type and have a forged steel elastic coupling running in oil.

The condensers are located directly under the turbines and have a cooling surface of 4250 sq. ft. (a little over 2 sq. ft per K.W.) The tubes are expanded in both heads.

The air pumps are a modification of the Edwards combined air and condensate pump. They are motor driven, the motors being of the slip ring type, with liquid starting resistance.



Electrically Driven Air Compressor

Generators

The Generators consist of one General Electric and two A.E.G., all three phase, 50 cycle, 3150 volts, 3000 R.P.M., with direct connected exciters.

Switch Boards

One H. T. 13 Panel Switch Board of black marble brought from Greece, Europe, serves the H. T. outgoing feeders and the transformer primaries. Each generator panel is equipped with the following instruments:

1 A. C. Voltmeter.

Nos. 1 and 2 Turbo Generators.

1 A. C. Ammeter.
1 A. C. Watt-meter.
1 Poly-phase integrating Watt-meter.
1 Demand recording Watt-meter.
1 D. C. Voltmeter (Excitation.)
1 D. C. Ammeter, (Excitation.)
2 indicating lamps for circuit breakers.
1 Frequency Meter.

The Generators are protected by circuit breakers, each fitted with two type B definite time limit relays, circuit opening type.

The Generator main switches are hand operated, oil breakers. The H. T. feeder circuits are protected by inverse time limit relays opening type.

The L. T. switch board consists of 12 panels, black marble and is used for local distribution at 550 volts, The L. H. feeders are protected by no voltage release fitted to the oil breakers.

The cooling air to the generators is washed by being passed through a Canadian Blower and Forge Company's carrier air washer, size 10 ft. 7¼ in. x 4 ft. x 10 in. with 80 sprays having a delivery of 144 gals. per minute. The velocity of the air through the washer is 500 feet per min. It is guaranteed that 98% of the solid matter carried by the air will be removed.

The station voltage regulation is obtained by G. E. voltage regulators.

The transformers are located in a brick building 31 ft. x 15 ft. x23 ft. high situated at the back of the power house. There are two Canadian General Electric step-up transformers 2?5 K. V. A. each, stepping up from 3150 to 11,000 for transmission to Thorburn Colliery. Two step-down transformers 350 K. V. A. each stepping down 3150 V to 525 having a full load eff. of 98%. Four 10 K. V. A. lighting transformers 525 V to 113 V.

All lines protected by Canadian General Electric graded shunt resistance multi-gap lightning arresters.

Busbar Room

The busbars are located in a room below the H. T. switchboard gallery 10 ft. wd. x 6¼ ft. high x 43 ft. long. There are two sets, (duplicates) of buses, oil breakers and isolating switches. The switches are placed in cells and are separated by concrete dividing walls. The busses being also separated by concrete wall. Throughout the whole electric system within the power house walls is carried out a color scheme so that any certain feeder, lead or earth connection can be located instantly at any point of the extensive system by referring to its color. The colors used are for the main generator leads, feeders, busbars and outgoing circuits—"red," "green" and "yellow" and "blue" for earths. Not only is this a convenience but adds to the beauty of the whole layout, the busbar room and cells being done in pure white.

There is also another feature worthy of note. There is a system of signal (bells) connected with the voltage regulator that rings an alarm to the engineer when there occurs an unusual disturbance of the line voltage.

The whole station is a thing of beauty,

Showing Low Tension Switchboard, and Alarm Signal Bells

as well as efficiency, not a speck of dirt, dust, oil or grease to be seen anywhere, and this at a pit mouth is the last thing one would expect.

The floor consists of special terrazzo flooring laid on re-enforced concrete. The floor, with its beautiful finish, and the black polished marble switchboard, with nickled instruments and nickled hand wheels for operating the oil breakers, the polished steel and brass mountings on the turbines, the bodies painted dead black, make a beautiful combination. The walls are white and the illumination at night is almost perfect. Not that there is an over abundance of lights but they are well placed and every part of the power house is a reflector.

Operation

In the generator room there is an engineer and assistant on duty eight hour shifts. Readings are logged every hour and averaged every shift. Reports are made in triplicate, one being filed in the power house, one sent to the chief electrician and one to the chief engineer.

In the boiler room there is on duty two men, a fireman and assistant, and one man in the pump room. Besides this there is one repair man and two cleaners, all under the supervision of the Combustion Engineer.

All repairs are made on the plant at the Company's machine shop, which is directly under the supervision of the Master Mechanic, Mr. W. Fraser.

TORONTO LODGE C. A. S. E.

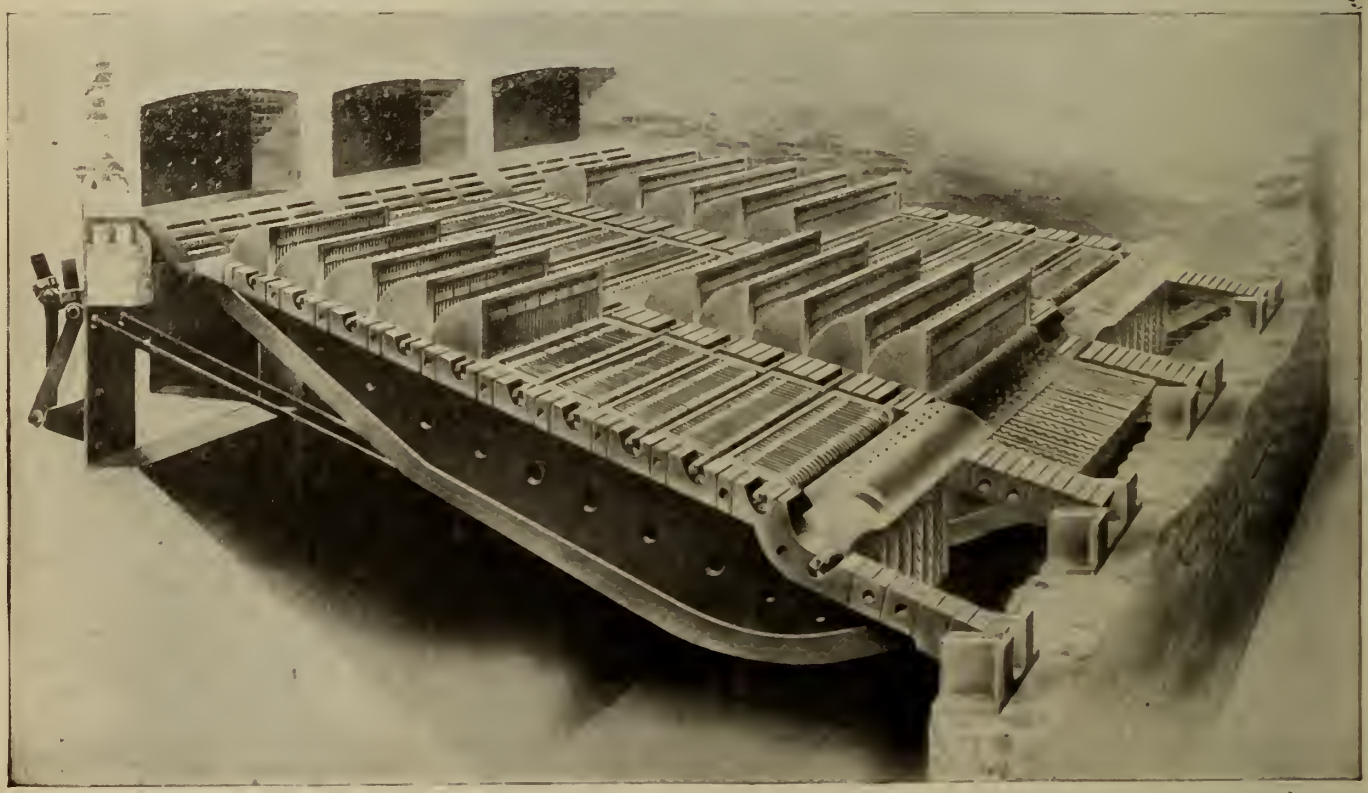
Toronto Lodge No. 1 C. A. S. E. are holding an open meetingto celebrate the opening of the new lodge room on Tuesday October 18 at 8 P. M. The entertainment will be held in the new room, which is situated in Cumberland Hall, Cumberland Street, the entrance being on Cumberland Street. The evening will be a guessing competition of an unusual sort. Invitations will be sent out, and a card accompanying them will contain space in which the guest will put down the number of guests who will be present in his opinion. The guess which comes nearest to the actual number will receive a very handsome prize.

With the removal to the new meeting place, which will be much more commodious and central than the old hall, the Toronto Lodge expects to get a largely increased membership, and with the live educational programme they expect to carry out, a most successful season is anticipated.

Messrs. Green Tweed & Co. New York have issued a circular describing their new brand of packing "Palco" which they are placing on the market. Palco has been designed for service on steam and hydraulic glands where the pressure does not exceed one hundred pounds per square inch and the element of very high temperature does not enter. It is a solid plaited packing thoroughly impregnated with graphite.

Files Stokers

Hand Operated



Simplicity—Ruggedness—Effectiveness—outstanding features of Files Stokers

Due to the absence of complicated and intricate parts, the average fireman is well able to operate the stoker with maximum efficiency—expert or expensive labor is unnecessary.

Clinker is ground out, ash and refuse removed, coal distributed—the fire is kept clean, uniform, rich—all by the easy, simple movement of the pull-rods at the boiler front. Not once are the fire doors opened to perform any of these operations. Cool air—that destroys draft, chills heated surfaces and strains the boiler—is eliminated.

Consult the perspective view of the stoker. It illustrates the distinctive movement of the stoker bars and the method of removing refuse by means of the counter-balanced cleaning plate. There is no drop in steam pressure nor is live coke lost into the ashpit during these operations.

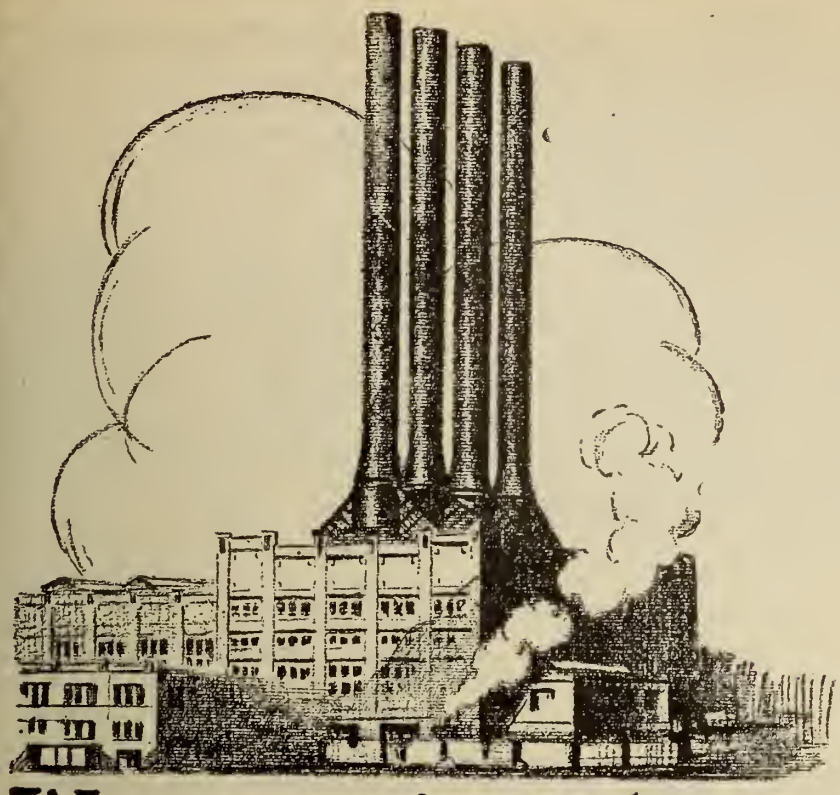
Perforations and corrugations throughout the various stoker parts provide constant circulation and proper distribution of air (absolute necessities for efficient combustion), and prevent warping or burning of these parts. Ample provision is made for expansion.

Combustion is complete at all times; maximum evaporation is guaranteed; overloads carried for long intervals are a natural requirement easily met by the stokers.

The entire stoker is designed simply but ruggedly; to insure continuous service with smallest operating and maintenance costs. Numerous plants — large and small—are benefiting from these exclusive features of Files Stokers.

Waterous

BRANTFORD, ONTARIO, CANADA



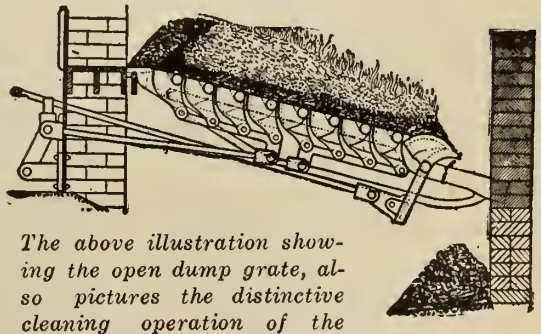
We are using six boilers now instead of eight

"Before purchasing your stokers, we operated eight boilers—we are using only six to-day. Files Stokers have so greatly increased our boiler efficiency that we are able to obtain sufficient steam from the six—the other two boilers are used as auxiliaries."

This is the way one client expresses the satisfaction derived from his stokers which are paying for themselves over and over again; they are enabling this concern to pocket the cost of operating two additional boilers. Yet the stokers are running on natural draft, burning 50% anthracite screenings! Instances such as these are not exceptional—they are the rule with Files Stokers.

Complete combustion, highest water evaporation, smoke elimination, continuously clean and fresh fires, are but a few of the direct results to be obtained.

Why not write us to-day for Bulletin "J" which contains all the interesting facts. There is no obligation.



The above illustration showing the open dump grate, also pictures the distinctive cleaning operation of the Stoker. This operation is easily performed without the necessity for opening the fire doors or without the loss of steam pressure. A single pull of the counter-balanced cleaning plate—that's all. Ash and clinker deposited on the plate are immediately dropped into the ashpit without the loss of any unburned fuel.

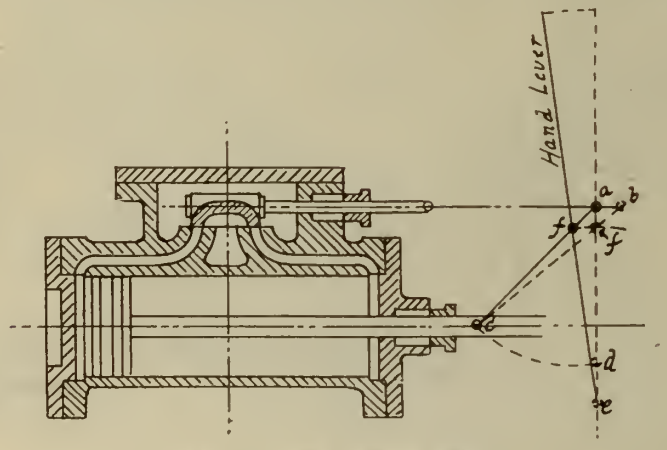
Waterous

BRANTFORD, ONTARIO, CANADA

A Lever Operating Engine

THE accompanying sketch shows a useful arrangement for operating by power, the levers of clutches, brakes etc. which require a greater force than can be conveniently got by means of a hand lever. These engines have been mainly used for reversing the link motions of large marine and hoisting engines, but there is no doubt, that if their principle was more widely known, they would be used more frequently, instead of the cumbersome systems of leverage which are necessary to get the force required down to that which can be exerted by an operator on a hand lever.

Referring to the drawing, the cylinder is a common steam engine cylinder, the only change to be made being that the slide valve has very little lap, the valve should for perfect action just cover the port openings, but for practical reasons it is necessary to have a little lap on the steam side, usually about a sixty-fourth to a thirty-second of an inch. The drawing shows a D slide valve, but a piston valve may be used instead if desired with the same results.



Design of Lever Operating Engine.

In operation the piston rod is attached to the lever or rod which is to be moved, by a pin connection or other suitable means, this connection is not shown in the drawing, as it will vary according to the work to be done. The control is by means of a hand lever, fulcrumed at any convenient point as e, and actuating another lever whose fulcrum pin is in the hand lever at f, which levers are for the sake of clarity indicated by center lines only in the drawing. The secondary lever is connected by links or other means to both piston rod and valve spindle. The piston is shown at the extreme end of its stroke, and when in this position the hand lever and secondary lever are in the positions indicated by the full lines. If the hand lever is now moved to its mid-stroke (vertical) position as indicated by the dotted lines, the secondary lever will be held stationery at one end by the piston rod, and its upper end will travel from a to b. This movement will draw the slide valve forward, and open the back port to steam causing the piston to travel forward.

As the piston advances it will carry with it the secondary lever, moving its lower end from c to d, and at this latter foint the upper end of the lever will have swung back to point a, and moved the slide valve back to its central position, closing the ports, and bringing the piston to rest at its mid-stroke, or precisely the position corresponding to that at which the hand lever has been set. If the piston becaus of the load against which it works, or through leakage of steam, should move in either direction from this central position, such movement of the piston rod will actuate the secondary lever and through it the valve spindle, and admit steam to the cylinder to arrest the movement, the action being to always hold the piston in the position indicated by the hand lever.

The power required at the hand lever is only that needed to overcome the friction of the slide valve, and the power that can be exerted by this engine may be whatever is required, being simply a matter of making the area of the cylinder sufficient to give the required power at the steam pressure available. The piston rod will move to any point in its stroke corresponding to the position of the hand lever, and maintain that position without further attention so long as the steam pressure is sufficient to overcome the resistance. The action in operating a brake is precisely the same as by hand, as any strain desired can be put on the brake from a slight pressure which can be gradually increased to the full pressure; or the full pressure may be suddenly thrown on, depending upon the manner in which the hand lever is operated.

The drawing gives only the general idea of the mechanism as the proportions will vary with the power to be exerted and the length of stroke desired, but its application to any given case is simple, as the parts themselves are simple, and the movements are easy to work out.

There is nothing about the mechanism to get out of order, and its upkeep cost is extremely low, much lower in actual experience than that of a system of levers which would exert the same force starting with that available on a hand lever. This because of the much smaller number of parts in the engine, the lever system having such a large number of pins and bearings that a little slack at each one soon totals up to such an extent of lost motion that the system fails to perform its functions unless kept in good repair.

In designing such an engine it is usual to cast the cylinder with a base for bolting to the floor, which base can be made to also carry the fulcrum bearing for the hand lever. Steam and exhaust connections to the steam chest are not shown on the drawing in order not to obscure the general idea, but must of course be provided for, as also drain cocks and lubricator.

The operating medium may be either steam or air, but if the latter is used, a piston fitted with cup-leathers is usually a better working proposition, than one fitted with rings, in fact if the engine is far enough away from the compressor to ensure always getting cool air, a solid piston if well fitted originally will give excellent results.

PULVERIZED COAL

Pulverized coal was first used in Portland cement industry, about forty-five years ago, as a fuel for heating the kilns in which the raw materials were burned. The experiment failed at that time, probably because the coal was not crushed finely enough. Methods and devices have since been developed, however, which have made it possible to use powdred coal as a fuel in many ways, and with great success. Some of the varied applications of pulverized coal, in addition to its use in cement manufacturing, are in connection with metallurgical furnaces, and for railroad-locomptive and stationary boilers. Wherever this fuel has been used under proper conditions, the results have been so satisfactory that there can be no doubt as to its value. A comparison of the costs of fuel oil, industrial (water) gas, and pulverized coal shows that, on a heat-unit basis pulverized coal is the cheapest.

Coal for pulverizing should be bituminous or semi-bituminous in character,—either run-of-mine or slack—and should preferably contain 30 per cent. or more of volatile matter. For ordinary uses, it should contain little or no sulphur. Recent experiments with anthracite and with inferior grades of bituminous coal, indicate that these will also give satisfactory results when properly manipulated, and that even anthracite culm, which has heretofore been considered of no value for pulverizing, may prove to be a suitable fuel.

In preparing pulverized coal it is first necessary to crush it to a size of about one inch. It is then carried by a belt conveyor to a magnetic separator, in order to remove any scrap iron or steel, which may be present in the coal, and which would cause trouble in the subsequent pulverizing process.

The next step consists in drying the coal until the moisture content is reduced to one per cent. or less. The first cost of the drying equipment is considerable, and for this reason undried coal has been used in a number of plants, and often with fairly satisfactory results. Moisture in the coal, however, is likely to cause trouble in the pulverizing operation by clogging up the machine; and in any event, the moisture must be removed before combustion can take place in the furnace. Hence, if the undried coal is used, the efficiency of the furnace is reduced to an extent depending on the amount of heat which is expended solely in evaporating the moisture in the coal. In addition, the temperature of the furnace is lowered considerably.

When dry, the coal is ground up to the requisite size in a pulverizing machine. There are several types of machines for this purpose, and the grinding is accomplished by the action of balls, rollers, hammers, or other mechanical devices. For satisfactory performance in the furnace the coal should be crushed so that about 85 per cent. of it will pass through

Elements of Machine Design—Lesson No. 1

Forces in Machines—What is a Force?—Classification of Forces —Stress and Strain—Elasticity and Elastic Limit—Modulus of Elasticity—Resilience—Working Stress

*By L. T. RUTLEDGE, BA. Sc.

A MACHINE is a combination of resistant bodies or links, whose motions are completely constrained and whose links are so arranged as to transmit motion to some particular part where useful work is to be done. The transmission of this motion gives rise to forces which must be resisted by the various parts of the machine through which the forces are acting.

What is a Force?

A force is that cause which produces the following effects:—

(1) Change of motion or acceleration of a body.

(2) An opposition or balancing of other known forces.

(3) A measurable deflection or distortion in elastic bodies.

The first item relates to kinetics which is that branch of mechanics that treats of the movement of solid bodies produced by forces not in equilibrium, as in the case of machines.

The second item relates to problems in statics, which treat of the laws and conditions of forces acting upon solid bodies at rest, as in the case of bridges and buldings. A force is clearly defined when its point of application, magnitude and direction are known.

Classification of Forces

Forces acting upon machine parts may be classified as follows:—

(a) Useful forces—In doing useful work for which the machine was originally designed: for example, the parts of a drill press must transmit the forces produced by the resistance offered to the cutting tool by the material to be drilled.

(b) Dead weight forces—These forces are present due to the dead weight of the individual parts of the machine. In many designs these forces are overlooked but in many structures such as cranes, or heavy gear wheels on shafting they cannot be ignored. In structural steel work the dead weight or dead load is a very important item.

(c) Frictional forces.—Frictional forces are forces caused by friction between moving parts as in bearings or guides. Where these forces exist, provision must be made for the transmitting of the energy necessary to maintain the force.

(d) Forces due to expansion and contraction—In some structures such as boilers, steam pipes, etc., provision must be made for the forces of expansion and contraction caused by heat. In steam mains expansion joints are provided.

(e) Forces due to change in velocity—Where the direction of motion is constantly changing, as in a connecting rod, or where an acceleration exists, forces are present due to these causes. The design of a flywheel is very complicated on account of the centrifugal forces due to its motion of rotation.

Now it should be quite clear that the designer of a machine must make a careful analysis of all the forces acting from any cause whatever. These various forces should be listed so that all will be provided for. Failures are due to the neglect of this very point.

2:—Stress and Strain

In engineering problems, the external forces acting are usually spoken of as the loads. These loads, coming upon the members of a machine, causes the latter to undergo a deformation or change of shape which is known as the strain. The very instant the strain comes into existance, an internal resistance is set up by the molecules of the material to oppose the strain. As the strain increases, the resistance to it increases until a state of equilibrium is reached. The internal reaction is known as stress. So that the stress may be defined as the internal reaction against the external forces that cause a strain in the material. Forces and stresses are measured by the same units, namely, pounds or tons per square inch. Strain, which is really a stretch, an elongation, or a shortening up is measured, generally, in decimals of an inch.

The purpose of this series of articles, is to provide a short course in machine design, dealing with the fundamental principles involved in the design and operation of machinery. A definite and concise system of reasoning will be suggested for the solution of practical problems.

The course has been designed in the first place, to stimulate interest among any connected with mechanical work, especially such work as draughting, designing, superintending, inspecting, etc., and any who have not received a college or technical school education but who, nevertheless, are desirous of increasing their knowledge in this particular branch of engineering. Many who may have already studied mechanics and machine design will find it advantageous to do some reviewing.

*The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, Mr. Rutledge will be only too pleased to offer assistance. To save time, write direct to Kingston, explaining your trouble in detail.

Elastic Limits and Modulii of Resilience in Tension.

Type of Steel		Elastic Limit	Modulus of Resilience
Open-hearth Carbon Steels	.08 per cent carbon	25000	10.4
	.15 " " "	30000	15.0
	.30 " " "	35000	20.4
	.40 " " "	41000	28.0
	.50 " " "	47500	37.6
	.60 " " "	63500	67.2
	.70 " " "	70500	82.8
	.80 " " "	75000	93.8
Alloy Steels	Nickel Steel 2.85% Ni — Annealed	52000	45.1
	Nickel Steel 2.85% Ni — Oil-tempered	121000	244.0
	Chrome Steel — Oil-tempered	127500	271.0
	Nickel Vanadium — "	126250	266.0
	Chrome Vanadium — Annealed	63.700	67.5
	Chrome Vanadium — Oil-tempered	170.000	482.0

Table 1.

The relationship between loads and stresses is very simple. If a pull of 3,000 lbs. is maintained on a fastened rod, then the stress in any cross section of the rod at right angles to the direction of the forces is 3,000 lbs. If the cross-sectional area of the rod is 3 sq. in. then the unit stress is 1,000 lbs. per sq. in.

Therefore, if "P" were the load acting on a member whose cross-sectional area is "A" then the unit stress "S" $= \frac{P}{A}$

When a body is stressed, there are always, at least, two forces acting. For example, consider a short post resting on a concrete block and let the post be loaded on the top with a weight of one ton. Where are the two forces? It is certain one of the forces is the weight on the post and the other must be the upward resistance of the concrete equal in magnitude to the downward force. If there were no opposing resistance the post would move downwards under the action of the weight and it would keep going till opposed. It is very important to realize fully that there must be, at least, two forces present for equilibrium.

Kinds of Stress

(a) Tensile stress or tension occurs when the opposing forces acting upon a body tend to pull it apart as in the tie bars of a bridge. Then the tensile stress is the internal molecular resistance, cohesion, etc., that acts to resist the separation of the material.

(b) Compressive stress or compression occurs when the opposing forces acting upon a body tend to compress or squeeze it and the particles of the body act to resist the crowding effect.

(c) Shearing stress or shear occurs when the opposing forces acting upon a body tend to cause one section to slide past another.

(d) Bending Stress, or bending, also called transverse stress is a combination of tension, compression and shear and is produced by loading a beam transversely. When the beam bends downwards the top fibres are in compression and the lower ones in tension. The load, in this case, tends to shear the beam in a vertical plane, the shear being maximum under the load. In addition, there is a horizontal shearing stress, brought about by the variation in the vertical shear and other conditions.

(3):—Elasticity and Elastic Limit

Elasticity is the property which a material possesses of returning to its original form and dimensions when the external forces causing distortion are removed. Steel is the most highly elastic material met with in practice. But within certain limits every solid body is elastic and the strain therein is directly proportional to the forces producing it. This is a statement of Hooke's Law. In other words the law states "that unit stress is proportional to unit strain."

The relation existing between the unit stress and unit strain for any material is best given by a diagram or curve, called the stress-strain diagram. The diagram is plotted from observations made when a test piece of the material is subjected to an increasing load and finally broken in a testing machine.

Where E_t = modulus of elasticity in tension

" S_t = unit stress in tension

" s = unit strain

Then $E_t = \frac{S_t}{s}$

Fig. 1 is a stress-strain diagram for a mild steel. The unit stresses in pounds per square inch are plotted as ordinates on the vertical axis, and the unit strain or strain per inch of length in thousandths of an inch. An inspection of the diagram shows how the steel behaves under load. It is seen that up to about 35,000 lbs. per square inch the diagram is a straight line, the unit stress being directly proportional to the unit strain.

At the point "B." the curve departs from the straight line. The behaviour of the beam of the testing machine indicates to the observer when this point is reached. The stress at the point "B." is called the elastic limit. It is the limiting point of perfect elasticity, that is, it is unit stress below which the strain disappears completely upon removal of the load or the elimination of the stress, or in other words, no permanent set can be detected. The point "C." is called the yield point and it is always quite close to the elastic limit. Beyond the point "C" the strain increases at a greater rate than the stress until finally rupture of the test piece occurs. The external load necessary to cause rupture divided by the original area of the cross-section of the bar is called the ultimate strength.

4:—Modulus of Elasticity

In order to determine the strain for any known load acting on a given material, it is very convenient to make use of a so-called modulus of elasticity. It is a factor obtained by dividing the unit stress by unit strain, the stress being not greater than the elastic limit. The value of this factor can, therefore, be obtained for any material from the straight line part of the stress-strain diagram. The slope of the line "A B" in Fig. 1 gives the value of the modulus of elasticity. The slope of a line is obtained by constructing a triangle, having the line as hypotenuse and having for the other two sides two lines, each parallel to an axis of the diagram, that is, have one vertical, and the other horizontal. Then the slope is given by dividing the opposite side by the adjacent. In trigonometry this ratio is called the tangent of an angle. Referring to the figure, the ration is B. D. A. D. Considering the case of mild steel it would be found that for unit stress of 30,000 lbs. per square inch the strain would be .001 per inch of length. Therefore the modulus of elasticity would be 30,000 divided by .001 or 30,000,000.

It is very important to know the modulus of elasticity for all metals and materials used in construction. It is a remarkable fact, however, that the modulus of elasticity of every steel is constant, or nearly so, no matter what the grade of the steel.

This is illustrated in Fig. 2. The diagram shows all the steels mentioned to have the same slope and the one straight line in the stress-strain diagram is common for all. Therefore the moduli of elasticity are equal and as was stated above, approximately 30,000,000 lbs. per square inch. The modulus of elasticity is a measure of the stiffness or rigidity of a material and since all grades of steel have approximately the same modulus of elasticity, it is apparent that a piece of soft, ordinary steel is just as stiff or rigid as the most expensive alloy steel of the same size and shape. So that, as far as stiffness is concerned and where strength is not considered and where the shock loads are not present, it is quite good enough to use a low-priced grade of mild steel.

5:—What Factors Determine Strength?

Though one grade of steel is as good as another as far as stiffness is concerned, it does not apply from the standpoint of strength. The quantities that determine strength are the elastic limit stress, the breaking stress, or ultimate stress, and the amount of maximum elongation possible. Table 1 gives the elastic limit for a few steels. The elastic limit of oil tempered chrome vanadium steel is 170,000 lbs. per square inch, which is five times that of machinery steel. The strength of a machine part not only depends on the strength of the material in it, but also on the shape and size of the section. This latter point shall be considered later.

6:—Resilience

Referring to the stress-strain diagram, it is evident that the area under the curve is the product of pounds and distance, the pounds being plotted vertically as stresses and the distances horizontally as strains. In mechanicsthe product pounds by distance, usually feet, is an expression for work or energy. Then the total area under the complete stress strain curve is the amount of energy required to rupture the material, while the area under the curve up to a certain point is the total work required to deform the material an amount equal to the deformation corresponding to the assumed point. If the assumed point be taken as the elastic limit, then the area

under that part of the diagram is the energy known as the resilience. This area in Fig. 1. is represented by the triangle A D B. Since the area of a triangle is one-half the product of the base and the perpendicular height or ½ (A D x D B), it follows

$$\text{That, Resilience} = \frac{1}{2}\left(A\,Se \times \frac{Se\,L}{Et}\right)$$

$$= \frac{AL\,Se^2}{2Et} \qquad (3)$$

In which A = cross-sectional area

Se = unit stress at the elastic limit

L = The length of the specimen

Et = modulus of elasticity in tension

Though the stress-strain diagram is plotted for test piece of unit dimensions, that is, 1 square inch in area and 1 inch long, multiplying by "A" and "L" converts it to suit the case of an actual bar.

However, if the specimen had a cross-section area of 1 square inch and a length of 1 inch, the symbols A and L will have disappeared from the equation (3) and the equation is reduced to

$$(2) \qquad \frac{Se^2}{2Et}$$

4:—This magnitude is the unit of resilience and is called the modulus of resilience. The modulus of resilience is very useful in mechanics of materials for comparing the capacity various materials have for resisting shock. Since the modulus of elasticity is practically constant for all grades of steel, it is seen that the capacity of two steels for resisting shocks varies directly as the squares of their stresses at the elastic limit. For example, the elastic limit of a certain machinery steel is 34,000 lbs. per square inch, and of oil-tempered chrome vanadium steel is 170,000 lbs, per square inch, the latter being five times the former. Then from equation (4), the capacity of the alloy steel for resisting shock is 5 squared or 25 times that of the machinery steel. This point relating to resistance against shock is a very important one for the designer to note.

7:—Working Stress and Factor of Safety

In general the maximum permissible stress induced in a machine member must be kept well below the elastic limit, so that the action of the load may be perfectly elastic. The stress used by the designer in determining the size of the part is known as the working stress. The number of times the ultimate strength contains the working stress is the factors of safety. The size of this factor varies from 4 to 29 with conditions, some of which are listed below. In the case of cast iron, which is brittle and which often has blow holes and bad spots, it is customary to use a high factor of safety, whereas steel which is very ductile and more uniform in structure admits of the use of a smaller factor of safety.

The magnitude of the working stress depends on the following conditions:

(a) Kind of material, quality of it, its chemical composition, elastic limit, ultimate strength, resilience, elongation properties.

(b) Is the application of the load steady or variable, and if variable, does it vary from zero to a positive maximum or from a positive maximum to a negative maximum?

(c) Is the part subject to shock loads?

(d) Is the stress produced from the application of the load a simple stress or a compound one and what kind of stress is produced?

(e) Is the material used in the construction reliable and all the same as the sample tested?

(f) Is the material of the machine part subjected to unnecessary and speedy deterioration?

(g) Cost of manufacturing.

(h) The demand on the machine at some future date.

(i) Is human life or property endangered in case any part of the machine fails?

(j) Is the machine to be designed to do a certain work for a short time only and then be scrapped, or is it to be a part of a permanent equipment.

(k) Have temperature stresses to be considered?

OIL FUEL IN 1921

Lloyd's "Register of Shipping" gives the following interesting information in reference to the use of Oil Fuel for ships. In 1914 there were 364 steamers of 1,310,000 tons fitted for burning oil fuel, whereas at present there are 2,536 such vessels of 12,797,000 tons, the amount being more than nine times larger than that of 1914.

The percentage of total gross tonnage using oil, etc., in internal-combustion engines in 1914 was 0.47 and in 1921, 2.0. The percentage using oil fuel for boilers was 2.62 in 1914 and 20.65 in 1921.

Heat and Temperature

THE two words heat and temperature seem to be responsible for a lot of misunderstanding among men who should know perfectly well just what they mean. To the steam engineer it is absolutely necessary that his mind should be clear as to the difference between heat and temperature if he is to understand properly the principles of his work. Probably a good deal of the misconception arises through our use of the terms hot and cold to indicate slight differences of temperature that are apparent to our senses. Thus we speak of ice as being cold, and boiling water as being hot, by which we mean that there is a difference of temperature between them which is easily seen. However, if we consider their relative temperature as measured from the absolute zero of temperature the difference is seen to be much less than when we consider the mere thermometer range of temperature. Thus ice at 32 degrees by the thermometer, is at an absolute temperature of 492 degrees, while water when boiling is at an absolute temperature of 672. When we consider the heat contained in a quantity of water at different temperatures we have to consider not only the heat that is shown by the thermometer, but also the heat that has been put into the water to change it from the state of ice to that of water, and which heat is not shown by any method of measurement. That is the familiar latent heat. If the engineer can divorce in his mind temperature and heat, and get a true idea of each, he will find many problems much simplified. Suppose it were possible to reach the absolute zero of temperature, which has not yet been achieved, we would have a state where there was no heat of any kind and no temperature. Now if we had one pound of water at just one degree above absolute zero, we would have a definite quantity of heat, that is, I.B.T.U. Now, if we increase the amount of water to 1000 pounds at the same temperature we should have a quantity of heat equal to 1000 B.T.U. approximately, that is more heat than is required to change a pound of water at boiling point into a pound of steam at boiling point. Of course we could not have a pound of water at any such temperature, but this is merely used as an illustration. Large amounts of heat can exist at very low levels of temperature, but unfortunately it is necessary for us to utilise our heat resources at high levels of temperature in the heat engine as we know it.

Strong For Education

THE National Association of Stationary Engineers, which is the United States body of stationary engineers, have been holding their annual convention at Evansville, Ind. This probably has not much interest to the Canadian engineer, but the actions of a body composed of 19,000 members is worth looking at, anyway. The thing that stands out from this convention is the great stress laid on the educational activities of the Association, and the practical interest shown in this subject. For instance, it was urged that the educational work should be carried along as in the past, that it be made more effective, and that the board of directors consider the appointment of a permanent salaried educational secretary. Another point urged was that there should be close co-operation between the local and state associations and the engineering schools of the respective states. In this connection, it was stated that in Indiana, the engineers had the services of no less than thirty-six specialists for lectures on subjects of interest to them in their profession. This seems to us an excellent idea, and one worth the attention of stationary engineers' societies in Canada. We have not the least doubt that if the matter was properly approached, it would be possible to get the services of professors of engineering to deliver lectures to the members of these societies, on any subject that the latter would wish. Such lectures, if obtained say once a month during the winter, would be of the greatest possible value, and being presented by men whose occupation is that of imparting knowledge, there would be no doubt of the clarity of their exposition. This seems to be worthy of consideration by those who have the interest of the engineer at heart.

Progress in New Equipment

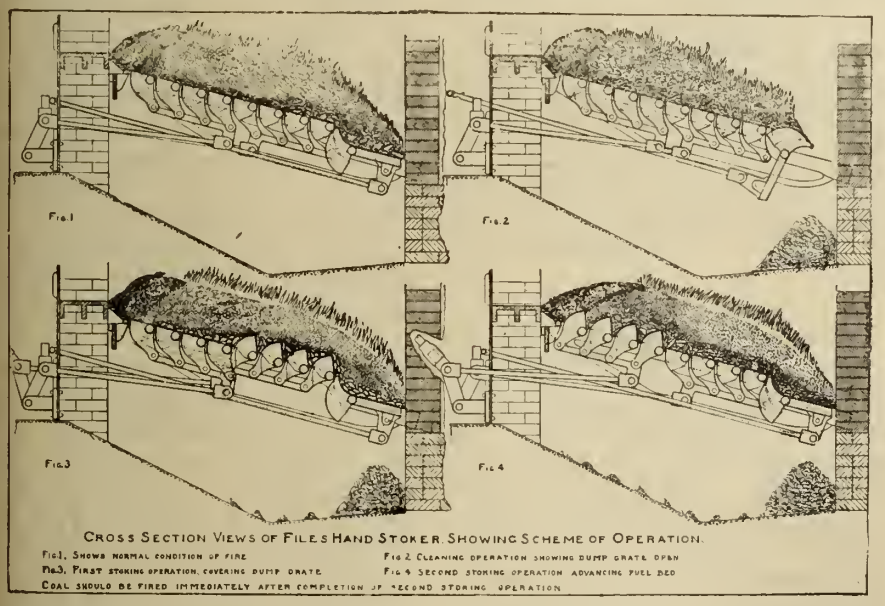
THE FILES STOKER

Although the Files Stoker has been in use in the United States for some time, it is just now being introduced into Canada by the Waterous Engine Works Company, Limited of Brantford.

The Stoker is designed to overcome the many defects and losses occasioned by the ordinary hand firing and cleaning and to meet the requirements of complete and efficient combustion viz: a correct proportion and distribution of air, a clean fire continuously maintained, and an even thickness of fuel bed in proportion to draft conditions and load.

Operation of the Stoker

The Stoker is of the overfeed type and the fire is under observation at all times.



CROSS SECTION VIEWS OF FILES HAND STOKER SHOWING SCHEME OF OPERATION.

Fig1. Shows normal condition of fire. Fig 2. Cleaning operation showing dump grate open.
Fig3. First stoking operation, covering dump grate. Fig 4 Second stoking operation advancing fuel bed.
Coal should be fired immediately after completion of second stoking operation.

Coal is coked on a coking plate and the foremost stoker bars, where the gases are driven off and properly consumed in their passage over the hot, incandescent fire bed.

The coked coal is gradually worked down the inclined surface of the stoker by the simple operation of the stoker bar handles situated at the boiler front.

This operation actuates the stoker bars vertically six inches into the fire, breaking up the ash and clinker formation and pushing it forward to the cleaning plate, at the same time advancing the unburned fuel toward the rear of the furnace and producing a condition whereby a free passage of air is obtainable throughout the entire fuel bed.

A single pull of the counterbalanced cleaning plate drops the ash into the ashpit without the loss of unburned coal or drop in steam pressure, and without entailing the extreme exertion on the part of the fireman required in cleaning the ordinary flat grate fire. This latter operation, necessary only at occasional intervals, is easily and instantly performed.

The result is a test fire condition at all times—free of ash and clinker, producing the highest and most efficient combustion to be desired.

It is claimed that these stokers can be easily installed at slight cost in a few days or over a week end. No alterations to boiler fronts are necessary other than drilling a few holes for positioning the operating levers, and when complete there are no changes in settings or objectionable projections and the boiler fronts are not defaced.

The makers state that all grades of bituminous coal, heavy mixtures of anthracite, culm or screenings mixed with bituminous coal or mixtures of coke and similar fuels, can be used with excellent results with the Files Hand Stokers, and that cheaper and poorer grades of fuel can be used with higher efficiency than is possible with better grades of coal on ordinary grates.

The flexibility of the shaking grate is combined with the advantages of stoker operation by which coal—high in ash and refuse,—is permitted to burn without causing the fire to become dirty or preventing the highest possible efficiency and capacity.

A saving in labor due to the installation of the Files Hand Stokers is effected over that required with ordinary grates.

When installed with proper settings, Files Stokers will, it is claimed, give absolutely smokeless combustion with any fuel. This is due to the same causes which make possible the increased efficiency of stoker-fired boilers as compared with that of hand-fired boilers; namely; rapid disposal of ash and clinker; a thorough cleaning of fires without disturbing the active fires; and an even bed of fuel at all times.

BRITISH ENGINEERING TRIUMPHS

Mechanical engineering is the very best basis of modern civilization, writes D. A. Bremner, O. B. E., director of the British Engineers' Association, in an article reviewing British achievement in this branch. Great Britain was the birth place, and for many decades the chief seat of mechanical engineering no matter how loud the boasts of persons across the Rhine. What is more the British set a high standard of excellence and reliability and this has resulted in a world-wide reputation for the products of their inventive genius and skill.

The basic invention was the steam engine in which Thomas Savery, 1698, and Thomas Newcomen, 1772, were the pioneers, although the achievement belongs to James Watt, 1736-1819. Four other British engineers developed the high speed steam engine, and then another series of great men perfected the marine engine, John Penn, and A. C. Kirk introduced the triple expansion engine. The reaction steam-turbine, which revolutionized marine propulsion and electric power generation, was invented by Sir Charles Parsons in 1844, and the condensing type of turbine in 1891. Eight great names, commencing with Brindley, 1756, are associated with the steam boiler. Stephanson, Webb and Worsdell created the locomotive.

Progress with any of these inventions would have been impossible without machine tools, and in their invention and development the British record is unique.

Large drilling machines and lathes were first made by Boulton and Watt at the end of the eighteenth century. The lathe slide-rest with leading screw and change wheels was invented by Henry Maudsley in 1800, the self-acting lathe by Sir Joseph Whitworth in 1835, the steam hammer by James Nasmyth in 1839, the planing machine by Richard Roberts in 1817, and the self acting planing machine by Sir Joseph Whitworth in 1835. Milling cutters or hobs for cutting toothed wheels and worm gears were invented by R. Bodmer in 1839, the shearing machine by G. B. Thornycroft in 1843. Sir Joseph Whitworth's screw stocks, dies and taps were patented in 1840. Composition emry grinding wheels by D. Fisher in 1856. Hydraulic machinery is associated the world over with the names of Lord Armstrong, R. H. Twedell, Fielding, J. and J. Platt, the last mentioned of whom invented hydraulic forging in 1885.

The construction of accurate machine tools, and the production of accurate work, either by machinery or hand processes, would have been impracticable without the use of surface plates. Sir Joseph Whitworth's method of producing such truly plane surfaces which he devised in 1840, was, therefore, a discovery of the first importance. The same may be said of his measuring instruments of unprecedented precision.

Since the time briefly chronicled above, up to the present day, British mechanical engineers have proved themselves worthy of their distinguished forefathers. The developments have, however, been so vast that it is impossible even to mention them here. The

recent world's record performances of British aircraft are fresh in the memories of all. The representative Britsh motor-car de luxe is universally conceded to stand in a class by itself. The Mitchell thrust block and bearing, a British invention, embodies a new principle of construction revolutionizing all preconceptions in regard to lubrication and the pressures sustainable by rubbing surfaces.

Reference may also be made to the valuable work done by the Britsh Engineering Standards' Association and the National Physical Laboratory, the benefits of which are not confined to Britain.

THE TRUSCOTT HIGH SPEED ENGINE

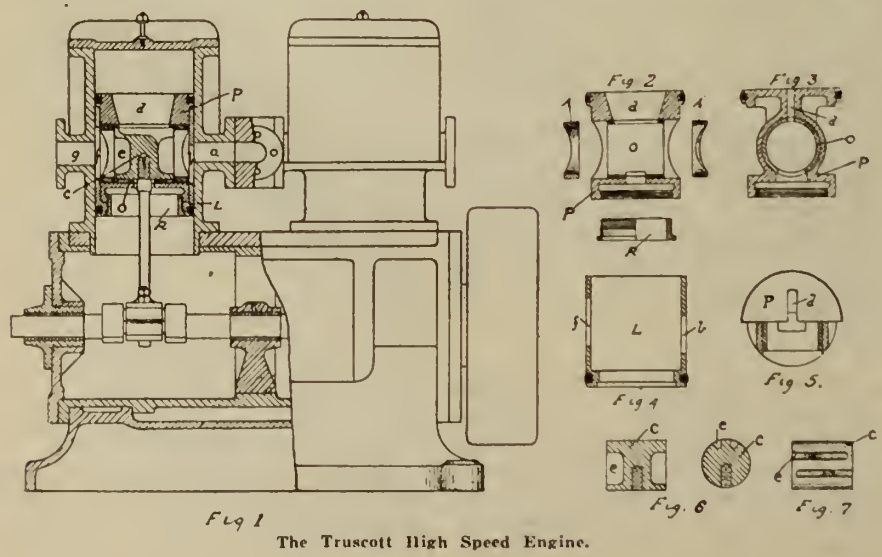
The Truscott patent engine is single acting, with twin cylinders, having cranks at 180 degs., and is for steam. The use of the term "steam" is intended to include other working fluids also. In the accompanying drawings, Fig. 1 shows an elevation of the engine partly in section, the piston having travelled through half its working stroke. Figs. 2, 3, and 5 show sectional and part sectional views of the piston body P, in the form of a light casting, with the port D preferably cored in position. The casting P, Fig. 2, is bored to take the liner O, together with the rings A and A1, a slot being provided of sufficient length to allow working clearance for the connecting rod, the said slot being situated in the manner shown, with reference to Figs. 1, 2, 3, and 5. The base of the piston body P is further screwed internally to receive the ring R, which is provided with a similar thread.

Fig. 4 shows a sectional view of the piston liner L, taken through the ports B and F. The liner L is turned a working fit to the bore of the cylinder, and bored to receive the piston body P, being further recessed to engage with the ring R.

Fig. 6 shows vertical sections of the gudgeon pin C the cavity E communicating with a port extending in line with the axis of the said pin, and situated on its periphery, this port being for exhaust. A similar port and cavity is provided for the inlet, being placed on the opposite side as shown. The pin C is bored and screwed to receive the connecting rod and turned a working fit to the bore of the liner O.

Fig. 7 shows an external view of the gudgeon pin C, in plan, showing the inlet and exhaust port E. Taking one cylinder only, the cycle of operations is as follows:—Commencing with the piston on the top dead centre, steam is admitted to the central chamber between the cylinders and flows through the passage A whence it passes through the piston liner L through the port B into the gudgeon pin C finally reaching the cylinder by the port D in the piston. The port in the gudgeon pin C is arranged for admitting steam to the top of the piston, with a slight lead, when on the top dead centre. The piston is thus forced down and steam is cut off when the top edge of the port B in the piston liner L is opposite the bottom edge of the port A in the cylinder wall. Expansion takes place until the bottom dead centre is reached, which brings the gudgeon pin central. Exhaust commences on the up stroke through the port E in the gudgeon pin C the steam finally escaping through the ports F and G in the piston liner and cylinder wall respectively, and thus to atmosphere.

The Anti Corrosion Engineering Co of New York, have issued a little pamphlet entitled "Water That Won't Rust" describing the method the company uses to make water harmless before it enters hot water tanks or boilers. The process is not in any manner in the nature of a boiler compound, but is a process of de-activation and de-aeration, which renders the water incapable of oxidising or rusting the material it comes in contact with the metal of the tank or pipes. It is claimed that with this process in use steel pipes can be made to last longer than brass pipes.



The Truscott High Speed Engine.

NATIONAL ASSOCIATION OF PRACTICAL REFRIGERATING ENGINEERS

The twelfth annual convention of th National Association of Practical Re frigerating Engineers will be held a Hotel Lorraine, Philadelphia, Pa., o November 30, and December 1, 2 and 1921. This is the first meeting of th Association to be held in the East, an it is confidently expected that it wi eclipse any previous gathering of refri erating engineers, even the successf convention which the Association held Chicago last December.

The gratifying growth of the Associ tion during the past few years, with i membership representing every sectio and almost every state in the Unio makes it reasonable to expect a reco attendance, and anticipating this th committee in charge of the conventio arrangements are making preparatio on a greater scale than ever before.

The program to be provided will i clude papers by men of world-wide r putation, who are being chosen becau of their familiarity with the particul subjects in which the membership, an refrigerating engineers in general, a interested. Also, there will be pape of interest to all groups of the refrige ating industry, including the employ and managers who will be welcome attend as visitors. Each year is sho ing an increase in the number of pla owners and plant managers who atte the sessions of the convention. Th are commencing to realize that duri the few short days the convention is session they can obtain valuable info mation as to plant operation. Along th same line of reasoning, many employe are making a practice of sending the engineers to these annual meetin They have learned that it is a good i vestment.

The Educational and Examini Board of the National Asociation Practical Refrigerating Engineers h recently had prepared under its supe vision a Lecture Course on "The Pri ciples of Refrigeration," in twenty par for the benefit of its members. Sta ing with Lecture No. 1, the Course sent to them at intervals of two week It is the most valuable work on that i portant subject thus far contribute and the Board is to be highly commen ed upon the results of its efforts.

Refrigerating engineers who are n now members of the Association wou do well to write the National Secretar Mr. Edward H. Fox, 5707 West La St. Chicago, for information, with t view of joining and availing themselv of the educational work it is carryi on, including the Lecture Course.

PATENT BOILER ALARM

To all whom it may concern:

Be it known that I, John J. Hines, a citizen of the Dominion of Canada, residing at Halifax, in the Province of Nova Scotia and Dominion of Canada, have invented new and useful improvements in Boiler Alarms, of which the following is a specification.

My present invention pertains to boiler alarms; and it contemplates the provision of a simple, inexpensively installed and reliable apparatus, calculated in the event of the water in a boiler getting dangerously low to apprise the engineer of the fact so that he can have the boiler supplied with water before any damage takes place.

The apparatus is designed more particularly for use on a marine boiler and will be fully understood from the following description and claims, when the same are read in connection with the drawing, accompanying and forming part of this specification, in which:

Figure 1 is a view diagrammatic in character and showing the application of my apparatus to a marine boiler, and also showing that when a vessel is rolling or pitching in a heavy seaway there is practically no rise and fall of water in the center of the boiler where my novel apparatus is preferably located, particularly when the apparatus is used on a marine boiler.

Figure 2 is an enlarged vertical section of my novel apparatus.

Figure 3 is an enlarged view, partly in elevation and partly in vertical section showing the upper portion of the apparatus.

Similar numerals of reference designate corresponding parts in all of the views of the drawings.

The boiler 1 may be of any type, and in furtherance of my invention, a pipe 3, preferably of iron, and a column 2, preferably of brass, are connected with the boiler shell, the connections being effected, in the preferred embodiment of the invention, through the medium of a sandwich joint as best shown in Figure. 2, the said joint including flanges 4 and suitable connecting means 5.

When employed in a marine boiler, as in Figure 1, the pipe 3 extends downwardly through the steam and water space to the danger level of the boiler—i. e., about one inch above the highest heating surfaces, and I would also have it understood that the preferred arrangement of the pipe 3 is in the center of the boiler perpendicularly and longitudinally, this in order that the portion of the water adjacent to the lower end of the pipe will not be materially effected by movement of the ship.

The column 2 extends above and outside the boiler shell so as to radiate heat from the water contained in the column into the atmosphere, and in order to increase the radiating surface of the column, which is hollow, the said column is made in convolute form as illustrated.

The upper end of the column 2 is flanged, as indicated by 7, and to said flange 7 is connected by bolts 12 or other suitable means a closure plate 8.

At 17 is a container, preferably of copper, and in the said container is a mass 22 of mercury or equivalent material. The upper portion of the container, which upper portion is numbered 14, in Figures 2 and 3, is carried through the plate 8 and a gland 13 thereon, and may, when deemed necessary be insulated from the said plate and gland.

At 15 in the upper end of the container 14 is a plug of insulating material which is preferably threaded into an enlarged portion of the container as indicated by 16, and screwed in the said plug 15 is a terminal 19 designed to be connected with the plus pole of a source of electric energy (not shown). At 18, and bearing in the container 14 and contacting with the mercury is a complementary terminal designed to be electrically connected with the alarm or alarms (not shown) through the medium of which the engineer and other persons in authority are put on notice when the water in the boiler is dangerously low.

Under normal conditions, the boiler pressure operates to force water up the pipe 3 so as to flood the column 2 which, as before stated, is outside the boiler. This water being stagnant and in a column adapted to radiate heat into the atmosphere, it follows that such water will be considerably cooler than the water within the boiler, and consequently the heat given off by such water will not operate to expand the mercury 22 to any material extent. In the event, however, of the water in the boiler falling below the end of the pipe 3, the said pipe 3 and the column 2 will be immediately occupied by steam of high temperature, and in consequence the mercury will be quickly expanded and caused to electrically connect the terminals 18 and 19 whereupon the alarm or alarms will be sounded.

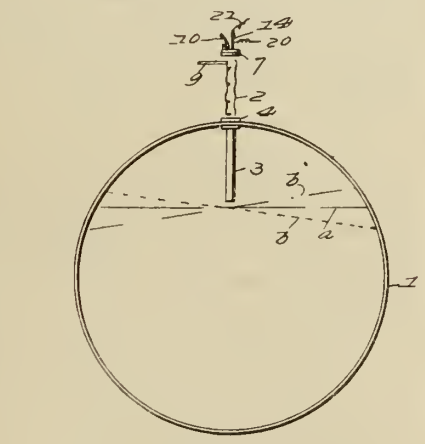


Fig. 1.

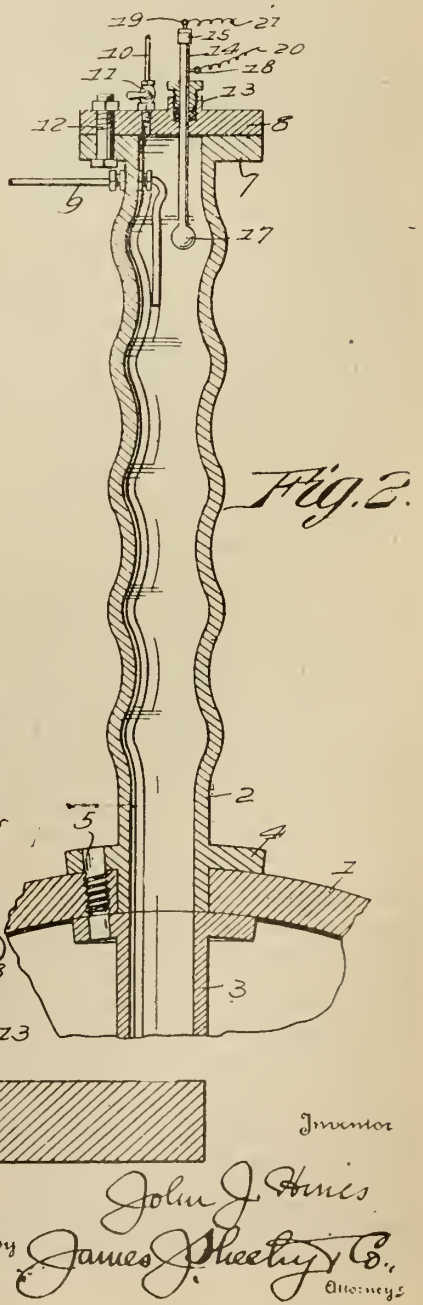

Fig. 2.

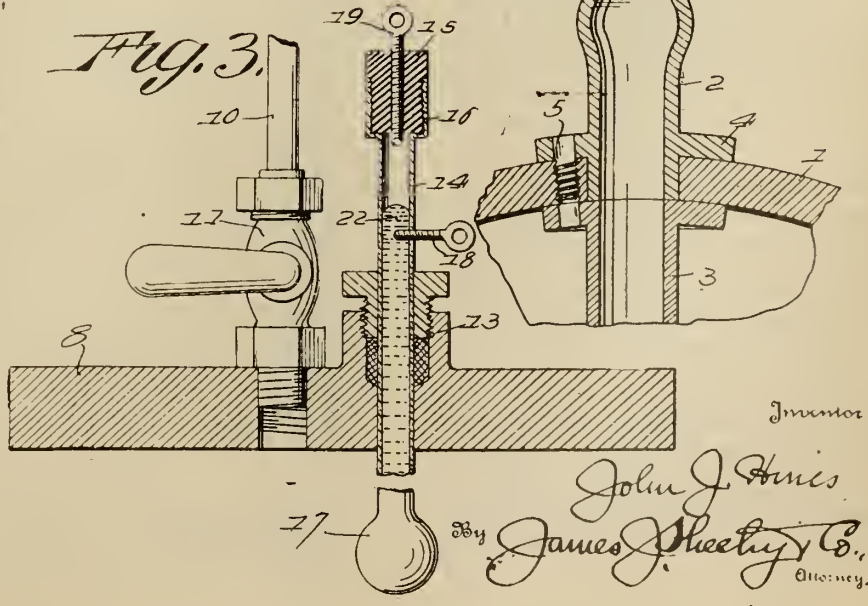

Fig. 3.

Inventor
John J. Hines
By James J. Keeley & Co.
Attorneys

Inasmuch as my invention does not reside in the alarm or alarms, I would have it understood that without involving departure from the scope of my claimed invention, any signal may be employed to apprise those in authority that the water in the boiler is dangerously low.

When desired a cock 11 may also be employed on the plate 8, the said cock being connected to a small bore pipe 10. This pipe 10 may be carried downwardly and equipped with a second cock (not shown) within convenient reach of the operator so that incidental to the operation of getting up steam in the boiler, air may be exhausted from the pipe 3 and the column 2. It will also be noted that when the last mentioned cock is opened, during the operation of the boiler, the column 2 will be filled with water of the same temperature as that in the boiler and the electrical circuit will be completed to sound the alarm and enable the engineer to make certain that the apparatus is in good working order.

Also when desired, a small copper pipe 9, Figure 2, may be let from the feed pump side of check valve into the column 2, adjacent to the mercury container 14—17. By virtue of this provision, feed water may be passed through the column 2 so that the temperature in the column will be the same as that of the feed water, and this condition will continue until the water level drops when by reason of the column being occupied by high temperature steam the circuit will be closed and the alarm sounded. It will be manifest that the feed water will pass through the said steam but will not appreciably diminish the temperature thereof.

Having described my invention, what I claim and desire to secure by Letters-Patent, is:

1. The combination of a boiler, a flanged depending conduit carried by the upper portion of the boiler within said boiler, an exterior hollow convoluted column provided with a flange portion at its top and a flange portion near its bottom and in alignment with said conduit, a closure plate secured to the flanged upper portion of the said column, a mercury container carried by said plate and depending within the column, a terminal secured to the container intermediate its length and normally in contact with the mercury therein, a second terminal carried by the upper end of the container and insulator therefrom normally resting out of contact with the mercury, and means for simultaneously securing both of the flanged portions of the conduit, and the column to the upper shell of the boiler in vertical alignment.

2. The combination of a boiler, a depending conduit secured to the upper portion of the boiler within said boiler, an exterior convoluted column secured to the upper portion of the boiler provided with a flanged upper end to which is fixed securely a closure plate, a mercury container carried by said plate and depending within the column, a terminal secured to the container intermediate its length normally in contact with the mercury therein, a secured terminal carried by the upper end of the container and insulated therefrom normally resting out of contact with the mercury, and a valved air pipe carried by the closure plate and depending within the interior of said column and leading to the atmosphere.

3. The combination of a boiler, a depending conduit secured to the upper portion of the boiler within said boiler, an exterior hollow convoluted column communicating in vertical alignment with and forming a continuation of said conduit and an increased radiating surface, a thermal circuit closing means positioned at the top portion of the column within the same, and a valved air pipe secured at the top of the column depending therein and leading to the atmosphere.

4. The combination of a boiler, a depending conduit secured to the upper portion of the boiler within the same, an exterior hollow column communicating with and forming a continuation of said column in vertical alignment therewith, a closure plate secured to the flanged upper portion of said column, a thermal circuit closing means carried by said plate at the upper portion of the column and depending therein and leading to the atmosphere, and a feed water pipe fitted into the top portion of the column and suspended therein adapted to maintain a uniform temperature within the column until the water in the boiler reaches the danger level.

5. The combination of a boiler, a depending conduit secured to the upper portion of the boiler within the same, an exterior hollow column secured to the boiler in vertical alignment with and forming a continuation of said conduit and increased capacity of radiating heat into the atmosphere; said column being formed of conductive material, valved means secured to the top of the column and in communication with its interior and the atmosphere, whereby air may be exhausted from both conduit and column thermal circuit closing means secured to the top of the column and depending therein, and a feed water pipe led into the top portion of the column adapted to prevent the temperature from rising within the column sufficient to cause an alarm before the water in the boiler reaches the danger level.

In testimony whereof I have hereunto set my hand in presence of two subscribing witnesses.

JOHN J. HINES.

Witnesses:
Fred E. Lordly,
W. H. Wilson.

NEW BRITISH ENGINEERING PROJECTS

In spite of economic difficulties whic are world-wide, serious attention is be ing given in Great Britain to many im portant engineering schemes. One o those is the construction of a ship can between the Forth and the Clyde. Statis tics have been placed before the Goverr ment with the object of proving that th construction of such a canal would at tract a profitable volume of traffic. An other important scheme is the construc tion of a railway tunnel beneath th Thames at Gravesend with connection to the railway systems north and sout of the river. The estimated cost of thi tunnel is £6,000,000 (six million pounds Steps are also being taken to re-organ ize the canal system of London, and im portant proposals were recently brough forward by a Government Committee.

STATIONARY ENGINEER AN ALDERMAN

It is somewhat unusual to find a station ary engineer who is also a member of th city council, but this is the case of Ale W. M. Stewart, of Sault Ste. Marie. Mr Stewart, who has had a wide experienc as a steam engineer, recently passed hi examination for the Ontario First Clas license, and is Chief Steam Engineer for th Algoma Steel Co. Like so many of th successful steam engineers on shore, Mr Stewart served his apprenticeship to mar ine engineering in the old country, and fo some years sailed in the U.K. and Canadia trade as an engineer, obtaining the Board o Trade certificate in due course. Mr Stewart also served in the Imperial Navy during the war, from 1914 to 1919, rising from fourth class engine room artificer t first class E.R.A. during his service.

Mr. Stewart also devotes his leisure time to instructing those under him, and during the winter months conducts a class in steam engineering, having the satisfaction o seeing many of his pupils gain their certificates in various degrees. That the men appreciate this service, may be gathered from the fact that his students last year presented him with a valuable gold watch suitably inscribed.

The Taylor Instrument Companies Rochester N.Y. and Church Street, Toronto, illustrate a number of their recording and indicating instruments in their catalogue No 1. A special feature of their recording thermometers is the dustproof and fume proof pressed metal cover, for situations where dust is met with in large quantities.

The Sarco Co. Inc., New York City have developed an indicating thermometer under Fournier patents, which is illustrated in a circular issued by the company. The thermometer is designed for both industrial and scientific uses, and can be furnished over a very large range of temperatures. The thermometer can be placed at any distance from the bulb, and the connecting tubing will not have any effect on the reading of the dial.

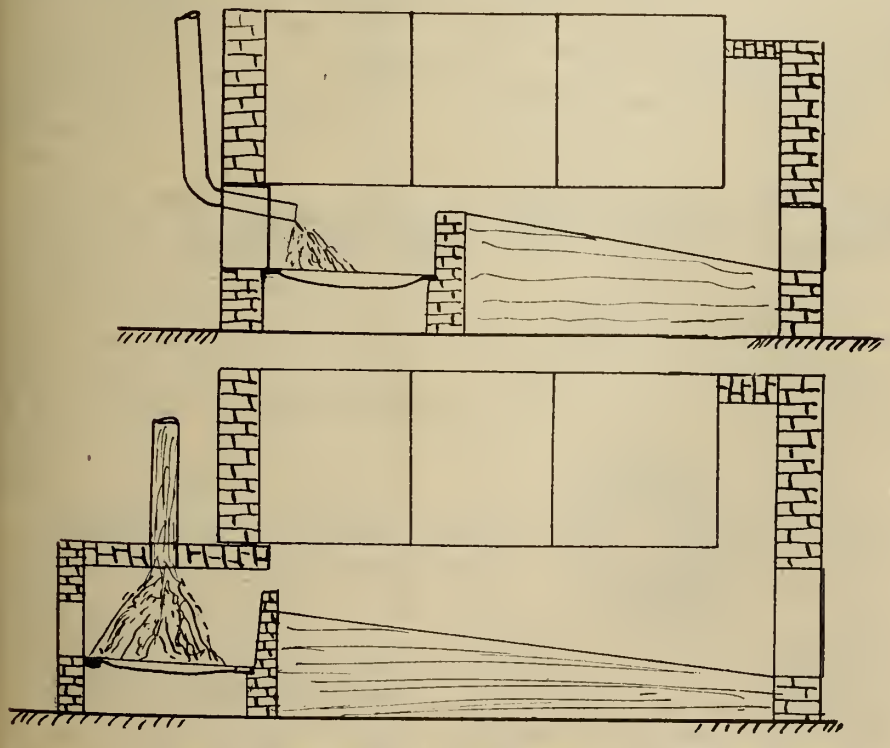
OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

FIRING WITH WOOD REFUSE

Question:—We have some boilers fed direct with wood shavings, and in my opinion the settings are unsuitable for this kind of fuel. I would like to have some one's opinion who has had experience with this problem. The trouble I find is that there is excessive heat in back of the boiler, coupled with high flue temperature, causing a loss of valuable heat. The enclosed sketch gives an outline of the present setting.

Answer:—The ordinary setting such as shown in our correspondent's sketch is not suitable for burning fuel consisting entirely of wood shaving or refuse. The method usually adopted is to build a Dutch oven or extension furnace, such as shown in the sketch below. The shavings are fed in on top of the extension furnace, where they form a pyramid on the grates, and leave plenty of room for air to pass through the grates in front of and behind the pile of shavings. When shavings are distributed evenly over fire grates it is very hard to get the necessary air through them to complete combustion. In the extension furnace, ignition takes place some distance in front of the boiler, and the flame impinges on the brickwork of the arch which acts as an ignition arch. The flames are thus not cooled by the boiler shell immediately on ignition, and there is plenty of room in the passage behind the extension furnace for the gases to be completely burned while passing through the combustion chamber and tubes of the boiler. In the ordinary setting the gases do not have time to be completely burned, and thus leave the tubes with a large amount of heat still available. The setting which is shown in outline, can be seen in any sawmill where shavings are used, which is the case in the majority of these mills. A door is placed in the front wall just as in the ordinary setting, and this is used for lighting up purposes and for cleaning. The extension furnace is usually about six feet long and the boiler should be set about four or five feet higher than the grates. The top arch may be of the suspended pattern or the ordinary brick arch, and the extension furnace brickwork should be well stayed with buckstays. The hopper through which the shaving pipe feeds should be cast iron set in the top arch.

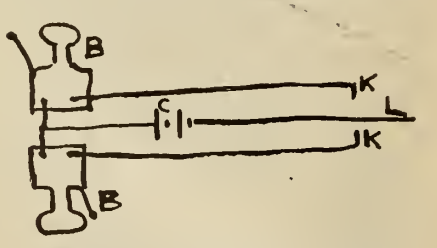


Top View Shows Setting at Present—Lower View, Dutch Oven Setting.

ANOTHER HEATING KINK

By C. Pye

Some trouble having been experienced in heating a building some distance from the boiler room, a simple device was adopted to remedy it. The building in question had to be kept at a temperature not exceeding 70 degrees, and not falling below 66 degrees. This meant a margin of only four degrees, and any encroaching on the



Arrangement of Temperature Alarm Bells

margin either way caused considerable trouble for the engineer.

Referring to the sketch, B. and B. are ordinary electric bells. V is a dry battery. One lead from the battery is taken to the two bells, while the other battery lead is connected to a copper wire L stretched over two insulators about 18 feet apart, with a sag of about two inches in the centre. The leads from the other terminals of the bells are taken to two copper nails, placed one above and one below the wire L, about one quarter of an inch apart. The bells are in the boiler room, while the wire L and the terminals of the two wires from the bell binding posts are in the room to be heated. The operation is simply that when the room cools the wire L contracts and makes connection with the top wire, ringing the top bell, and when the room gets too hot the opposite effect is caused. This little trouble saver has been in operation for some time and has given great satisfaction.

LONG LIVED BRITISH ENGINES

Many examples have come to light of British engines which have been at work from the very earliest days of steam engineering, The Science Museum in London has recently placed among its exhibits a pumping engine made in the year 1791 by Newcomon. This engine was at work until the year 1915 at a colliery near Derby. Another engine which was made in the early part of the 19th century has also been presented to the Museum. Both engines are still capable of doing useful work although they represent pioneer types very different from the British steam engines of today.

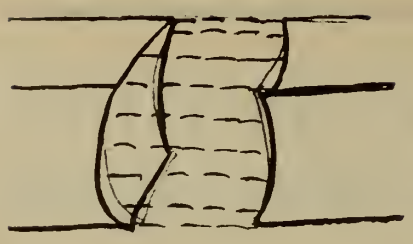
A GENERATOR TROUBLE

There sometimes occur in the course of an engineer's duties, peculiar happenings which can't be seemingly accounted for at the moment, and which may cause him considerable anxiety through not being able to cope with them. Sometimes when such is the case an expert is called in to determine what is wrong, and to advise us what to do to put it right. These gentlemen arrive, try to look intelligent and mysterious, smoke black cigars, and we presume, collect a fee, and depart, and that is all there is to it. The trouble remains, and we have to "go to it" ourselves. Such was the writer's experience and it is herewith presented as it may perhaps prove a help to some brother engineer who may have had a similar experience.

It was decided to install a new 4000 K.W. Unit in a plant which consisted of 2 1500 3000 R.P.M. 50 cycles. The new unit arrived and was duly installed. We were told by the erectors that a specially built exciter was being installed with it, and when the writer enquired, why it was special, no particular explanation was forthcoming.

Then the trouble began. Between the shaft and the frame of the machine heavy eddy currents were observed and measured. It was also noted that the designers of the set must have anticipated such a happening because they had gone to great pains to have the bearings at the exciter end carefully insulated with fibre shims, pillow block bolts with fibre washers and ferrules etc. Even the water and oil services to the bearings had fibre distance pieces fitted at the entering glands with the object, we presume, of combating the aforesaid eddy currents. The erectors sent several men at different times to try their luck at it, but all to no purpose. On this particular machine, the slip rings were placed between the exciter and the stator end bearing, and a thin perforated sheet metal cover was placed over them, and carefully insulated with felt. There were stiffening bars put between the exciter and the end bearing to carry this perforated cover. These were cut in half and joined together again with a vulcanite plate to ensure that no metallic path was between the end bearing and the exciter. After all these precautions had been taken, the eddy currents were still in evidence. It was found that there still was a path through the lock-nuts on the perforated cover. This cover was taken off and the machine was run without it with no further trouble. Of course this could not stop the eddy currents. The cause of these currents, in the writer's opinion, which may or may not be correct, is as follows.

Appended is a rough sketch of an Elementary Alternator developing 1 Volt at frequencies of 60 to 25 showing the effect of reducing the frequency. Since for the same number of poles the R.P.M. have to be decreased to decrease the frequency, increased flux is required to develop the same voltage. Hence in construction low frequency machines require larger magnets, increased number of turns in series on the armature coils and larger exciter units as compared with machines built for higher frequency. Vide Hawkins)



Frequency 60 Requires 3,600 R.P.M. per Volt, giving 37.777 L. of F.
Frequency 25 Requires Per Volt 1,500 R. P. M. 66.666 L. of F.

Taking the above ratios it follows that
3600: 3000: 27.777: x.
x—23147 L of force developed at a periodicity of 50 per second.

Therefore we must either increase the number of turns on the inductor field, or else supply a much larger current through that field. This had been done by installing a specially built exciter to supply the above heavy field current, and the nearer this field is excited towards the saturation point the more likelihood there is of strong eddy currents. This then was the cause of the trouble. The new 4000 K.W. Unit was a machine designed for running at 3600 R.P.M. 60 cyles per sec, changed to 3000 R.P.M. 50 cycles per sec by alteration of the governor gear. From an economical standpoint the 4000 K.W. Unit at 1000 K.W. requires at the exciter 167 Amps at 73 Volts about 16 H.P. while one of the small 1500 K.W. sets require for the same load (1000 K.W.) 62 Amps at 62 Volts or little more than 5 H.P.

PULVERIZED COAL

Continued from page 34

a screen 200 meshes to the inch, and about 95 per cent. through a screen of 100 meshes to the inch.

After pulverizing, the coal is conveyed to a bin, from which it is usually fed to the furnace by means of a screw conveyor in conjunction with an air blast. Both the coal feed and the air supply must be under positive control, in order to insure satisfactory results. The construction of the furnace must be such that the lining, after becoming heated will remain hot continuously, and the combustion chamber must be much larger than is necessary when an ordinary grate fire is used.

A more detailed description of the various methods employed for pulverizing and burning coal would doubtless be interesting, but enough has been said, already, to serve our present purpose, which is to call attention to the fire-hazard associated with the preparation and use of pulverized coal.

Coal dust is only one of a large number of substances which will explode when suspended in air in certain proportions, and ignited; and even when some element is lacking in the conditions that are essential to the production of a true explosion, the dust cloud may become ignited so as to give rise to a great sheet of flame, which in an inconceivably short time spreads throughout the room or other space in which the dust is suspended, and usually brings death to any person who may be in its path. A case of the latter kind, which occurred in a cement mill, is described in C. F. Herington's book, "Powdered Coal as a Fuel", as follows: "A foreman and some of his men were repairing and cleaning a mill. One of the men had rammed a piece of waste on the end of a stick into a part he was cleaning, and somehow (no one knows how) it caught fire as he pulled out. Immediately there was a hissing sound like a pinwheel going off, or like escaping steam, and in a flash this traveled the length of the room, down a stairway, and back several times, in layers just like a train of powder; only there was no report, no explosion,—just a hissing (accompanied, of course, by flame). The men who came out were absolutely nude, yet they seemed to retain their faculties. The foreman said, 'I'm done for and am going to die.' He was able to tell what had happened, before he became unconscious. They all died shortly afterward."

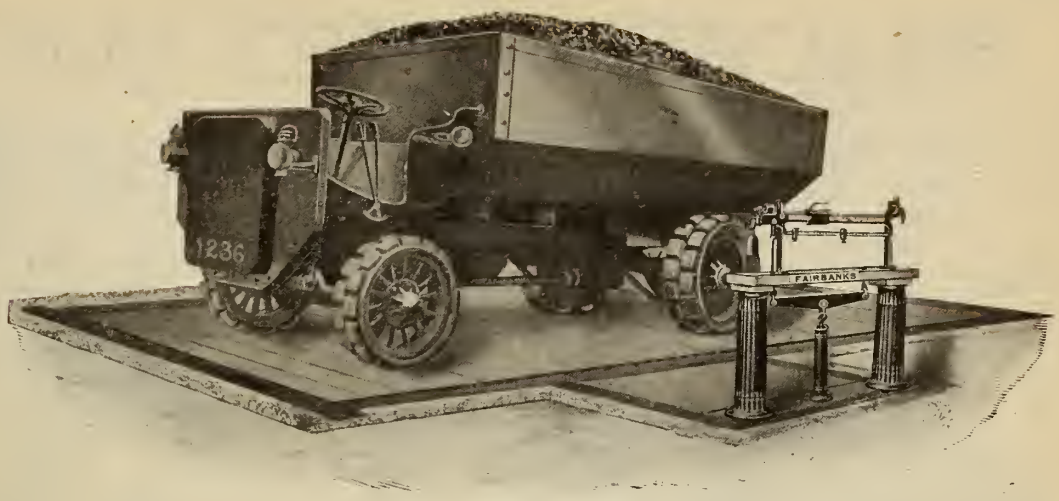
Recent disastrous dust explosions in grain elevators, which have caused large loss of life and enormous property damage, are doubtless still fresh in the minds of our readers. Coal dust is capable of producing similar results when it is fine enough and present in a sufficient quantity, and it should, therefore, be handled and controlled with great care. Grinding and pulverizing mills, unless properly inclosed, emit dust which settles on pipes, on overhead beams and similar structural members, and on all other objects in the vicinity. If these accumulations are dislodged, and the dust cloud so produced is then brought in contact with a flame or spark, an explosion of fire is almost inevitable. The source of ignition may be an open-flame light of some kind, or a spark produced by some metal object which has found its way into the pulverizing mill, or an electrical spark resulting from improperly grounded machinery, or an electric arc due to defective insulation of wires, or the arcing of a motor, switch, or other electrical apparatus, or the fire in a furnace or forge.

Experiments made by United States Bureau of Mines have proved that coal dust is not necessarily explosion-proof, even when largely diluted with other dust of an incombustible character. It was found for example, that a mixture containing 30 per cent. of powdered coal dust and 70 per cent. of finely powdered shale could be exploded. The fact that there may be a considerable inert dust in an industrial plant, in addition to coal dust, therefore does not eliminate the possibility of an explosion.

We have no desire to condemn the use of pulverized coal, nor to terrorize those who wish to adopt it; but we certainly do wish to emphasize the fact that fine coal dust is a source of serious hazard unless it is handled carefully and intelligently. Following are some of the precautions that should be observed in order to insure a reasonable measure of safety in the use of it.

(Continued on Page 48.)

Check Your Weights on Fairbanks Scales



The ever increasing use of motor trucks has created a demand for scales to stand more severe service than the ordinary wagon scale because most trucks carry approximately 85 per cent of the load on the rear axle.

Fairbanks Scales for heavy motor truck weighing, are designed to sustain 50 per cent of the capacity rating on each of the four bearings or 100 per cent on each end.

Fairbanks Auto Truck Scales are built to maintain accuracy under the hardest service.

A Fairbanks Scale will give you satisfaction.

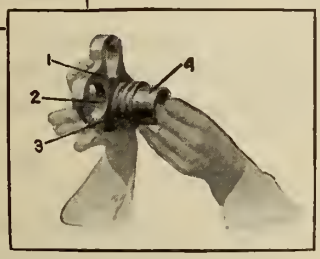
1. Rotating Disc
2. Port
3. Seat
4. SEALING BUSHING



Sealing bushing on inlet side makes it *double tightening*

The Yarway Double-Tightening Blow-Off Valve is of lever-operated, swing-gate type, with unique feature of sealing bushing on inlet side, making it double-tightening on both sides of gate.

The two illustrations above show clearly how sealing bushing establishes contact with rotating disc or gate when valve is closed. Guard on tailpiece of sealing bushing protects spring and prevents scale-forming matter getting behind bushing and interfering with spring action.

When no pressure is on valve, bronze spring holds bushing against gate. When line pressure is applied, bushing is forced up tight against machined surface of gate and is continually "ground in," resulting in an absolutely tight valve.

PULVERIZED COAL

(Continued from page 44)

First of all, it is highly important to prevent accumulations of coal dust particularly in the room where the pulverizing apparatus is situated. Powerful artificial ventilation is helpful for this purpose, but no great reliance should be placed upon it, especially in the angles and corners of a building, and in other places situated outside of the direct path of the air currents. The use of well-designed vacuum-cleaning apparatus is recommended, and the dust collected by means of such apparatus may be delivered to the pulverized-coal bin and used in the furnace.

Explosions are likely to occur in driers of the direct-heat type, where the hot gases come in contact with powdered coal or where red-hot cinders may drop into the screw conveyor which feeds the coal to the pulverizer. There are other types of driers available, designed and constructed so that this hazard is eliminated; and we recommend that preference be given to apparatus in which there is no possibility of direct ignition.

The coal should be delivered from the drier to the storage bin at a temperature not greatly exceeding 125° Fahr. Unless care is exercised in properly controlling the fire used for heating the drier, the temperature is likely to rise considerably above this point; and if the coal is delivered to the bin in a highly-heated state, and is left there even for a comparatively short time, it may take fire spontaneously while in storage. It is specially important, therefore, to have the drier operated by a competer and thoroughly skilled man. The fire that effects the drying should be drawn or effectively checked whenever it becomes necessary to stop the drier.

Back-fires from the combustion furnaces sometimes cause fires in the pipes through which the pulverized coal is distributed. These may occur if the air pressure in the distributing pipes drops below that in the furnace, on account of stopping the fan, or in consequence of an obstruction in the pipe line, or for any other reason. Every possible precaution should be taken to prevent such back-fires.

Fires which are probably due to spontaneous ignition are sometimes discovered in storage bins used for pulverized coal. As already indicated, these may be due, primarily, to the delivery of over-heated coal from the drier. The bins should be kept as cool as practicable, and this means that they should be located at a safe distance from furnaces, steam pipes, and other sources of heat. If there is reason to believe that stored pulverized coal is heating, a rough-and-ready idea of its approximate temperature may be had by thrusting an iron rod into the mass and leaving it there until it has attained the same temperature as the coal. When the rod is withdrawn, it will be easy to tell, from its temperature, whether the coal is dangerously hot or not.

In concluding this article, which is in no sense a complete exposition of the subject, we may say that the fire and explosion hazards of pulverized coal are comparable, roughly, with those of fuel-oil and gas. This fact is probably not realized as generally as it should be, and correspondingly less caution is observed in handling coal dust.

—Traveller's Standard

"Of all the auxiliary turbines in the plant the Sturtevant Turbines have been the most satisfactory....."

Two Sturtevant turbines driving boiler feed pumps were installed in a large power house in 1914. The units consist of Type "E" Turbines and 1,500 G.P.M. Centrifugal Pumps.

During this time one has run continuously and the other one used twice a day during peak loads. No repairs have been furnished for them for at least four years. In this same plant there are altogether 15 small turbines driving auxiliary apparatus of reputable make and the fact that the 2 Sturtevant Turbines were singled out for such praise is surely worthy of consideration. We direct connect

Sturtevant TRADE MARK **Turbines**

with any make of centrifugal pump and will erect both apparatus upon a suitable sub-base of cast iron. However, if the purchaser desires, we will ship the turbine direct with a flexible coupling between turbine and pump ready to erect upon his own foundation.

Our engineers will be glad to consult with you before selecting your turbines. Sturtevant Steam Turbines are used to drive exciters, boiler feed pumps, house pumps, fire pumps, fans, blowers and special equipment and for whatever purpose you need auxiliary drives, they will advise you which is most adaptable and profitable.

Write now for bulletin.

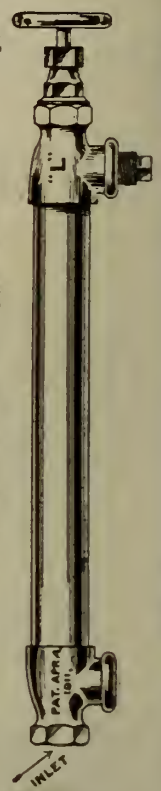
EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House. P2H

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.

Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap



Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admissions of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds.

Being open at starting, it cannot become air bound, this doing away with air cocks or vents — Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

Write for further explanation to

For

Self-Promotion And Sales Promotion

Are you interested in any of these fields—power—metal working—marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric, Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)

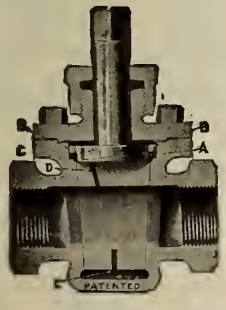
HOMESTEAD Quarter-Turn Valves



Convenient!

Contrary to the eight or ten turns with an ordinary globe or gate valve, the Homestead requires but **one** quarter turn!

Adaptable!

For air, steam, water, oil or acids. Made in Straightway, Threeway and Fourway patterns.

Leak-Proof!

Tightness is absolutely assured by a patented wedging cam that automatically forces the plug downward in closing.

Long Life!

Made of Brass, Semi-steel and special Acid-resisting Metal.

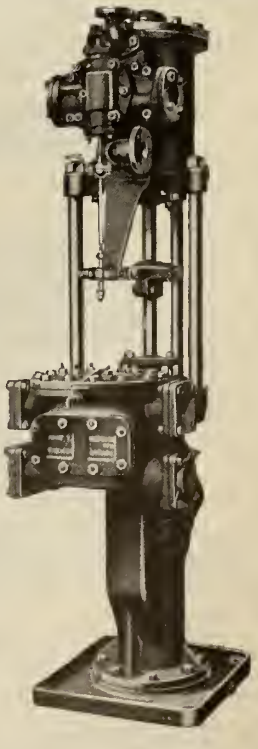
Homestead Valve Mfg.Company

Pittsburg, Pa. Works: Homestead, Pa.

HEPBURN PUMPS



Our Special

THIS HEPBURN "SPECIAL" Outside Packed Ram Pump is more efficient than a piston pump and upkeep charges are less. Designed for high steam pressure and for water of high temperature. Only one packing gland to need attention and no bucket rings to change. The valve motion is extremely simple and positive in action. No loose parts —No adjustments necessary.

We also make Cranes, Castings and Forgings

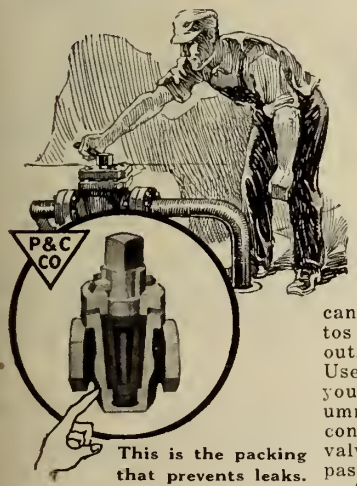
For Boiler Blow-Offs



This is the packing that prevents leaks.

To eliminate the constant trouble and money loss caused by leakage past your boiler blow-offs, install Pratt & Cady Vulcanized Asbestos Packed Cocks.

Their unique design provides for the inequalities caused by expansion and contraction and keeps the valves tight under severe conditions.

The plug has no metallic bearing. Instead it seats tightly within a special vulcanized asbestos bushing. Asbestos packing is employed throughout.

Use these dependable cocks on your main boiler and water column blow-offs, and in the feed connection between the check valve and boiler. Also unsurpassed for use on oil, air, gas and water, wherever a globe or gate valve fails to give satisfactory service.

Pratt & Cady Valves cover a complete line for every class of service.

Our valve book sent free on request.

PRATT & CADY CO., INC.

Manufacturers of Valves and Asbestos Packed Cocks that give long and satisfactory service.

Factory, Hartford, Conn.

The Canadian Fairbanks-Morse Co., Ltd. Halifax, St. John, Quebec, Montreal, Ottawa, Hamilton, Windsor, Winnipeg, Saskatoon, Calgary, Vancouver, Victoria.

Shipment of Four 150-H.P. (72"x18) Return Tubular Boilers for 150 lbs. working pressure.

E. LEONARD & SONS, Limited
Head Office & Works, London, Canada
Branches and Agents from Coast to Coast
Established 1834

LEONARD

KEEP YOUR BOILERS CLEAN
TO SAVE FUEL

⅛-inch Deposit on Tubes Increases Coal Consumption 30%
¼-inch Deposit on Tubes Increases Coal Consumption 66%
½-inch Deposit on Tubes Increases Coal Consumption 150%

MILLER'S BOILER CLEANING EXTRACT

Will remove ***all*** deposit in any boiler and will prevent ***any*** deposit forming in any boiler, no matter what the water supply is, ***without damage*** to Tubes, Joints, Brasses or Packing.

LUNKENHEIMER
Regrinding Valves

LUNKENHEIMER Regrinding Valves have firmly established their unparalleled merit by the successful results they have given in all classes of service.

The metal to metal seat—ground to a tight fit, forms the ideal seating surface to resist the wearing action of steam at high velocity. And the fact that the seating surfaces can be reground (an inexpensive operation easily accomplished), makes the renewal of parts wholly unnecessary.

Their extreme durability due to correctly proportioned parts, high quality materials and expert workmanship insures economy in maintenance.

Globe, Angle and Cross, and Horizontal, Angle, Vertical and Swing Check Patterns.

Specify LUNKENHEIMER and insist on their installation. Distributors of Lunkenheimer Products situated in every commercial center.

Which Stoker?

—You Make this Decision Once—It Must be Right

EXPERIMENT with any equipment is costly—but experiment with mechanical stokers is out of the question. The investment is large; it is made once in a lifetime; snap judgment won't do—**which stoker?**

Canadian plants want greater boiler capacity—continuous power day and night when necessary—they want this accompanied by greater economy in burning Canadian coals and by lower labor costs.

This means **high-duty stoker firing,** best exemplified by the Jones "A-C" (Automatic-Cleaning) Stoker.

Regardless of the size of the plant, the grade of coal burned or the local conditions to be met, the logical, safe answer to **"which stoker?"** is Jones "A-C."

The new "A-C" catalog goes into detail. Jones engineers, with unmatched experience in this specialized field, will gladly make a survey of your plant and give you the full benefit of the best they have learned in installing stokers in many prominent power houses. Investigation implies no obligation.

Jones Stokers are made in Canada by Canadians, and are sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized, and the reorganization makes available for Canadian power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

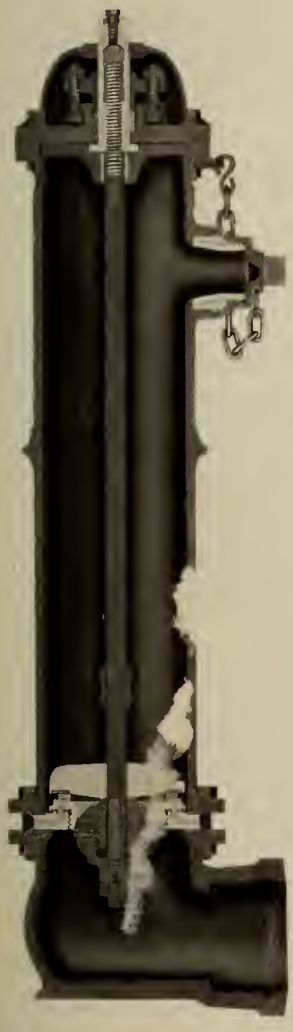
DARLING
PATENTED

The Perfect Hydrant For All Purposes



Made in Canada

Some of the Qualities of the DARLING HYDRANT

COMPRESSION VALVE—Closes with the pressure and prevents water escaping should barrel be broken above valve.

LARGE BARREL—Delivers water to nozzles with no loss of pressure.

INTERNAL PARTS—Including main valve and drip valve seats, easily removed through top of hydrant.

OPERATING THREADS—Are at top of hydrant, protected from injury and accessible for lubricating.

COMPRESSION DRIP—Dependable and cannot be clogged.

STUFFING BOX—Bolted pattern and cannot work loose in operating hydrant.

LENGTHENING HYDRANT—The only part required is an extension piece of the desired length.

VALVE ROD—Is in one piece and is free from torsonial strain.

WORKING PARTS—Are made of bronze, excepting valve rod, and it works in a bronze operating nut.

FLANGED CONNECTION—To hydrant base permits pointing the nozzles in any position.

VALVE—Is made of sole leather, the best material obtainable for the purpose.

BOTTOM OF BASE—Comes on level with water main and does not require excavation below main.

MORRISON

HIGH-GRADE

STEAM GOODS

The Survival of the Fittest

IN this age of strenuous competition only those commodities which meet the most exacting demands of careful buyers are able to survive for any length of time.

Morrison Steam Goods have been on the market for forty years. During this time they have won widespread popularity in Canada wherever Steam Goods are used.

They survive the test of time and shocks of changing conditions because their quality, workmanship and design is fully recognized by the engineering profession.

CRANE

"Y" PATTERN STOP CHECK VALVES

Note These Features:

Disc and piston in one piece.
Disc may be reground readily.
Full length bearing of disc in liner.
Will operate in vertical or horizontal position.
Deep throttling lip to prevent chatter on light loads.
Liner or stem cannot be cramped by pulling up yoke bolts.
Readily removable seat which is integral with the liner or dash pot.
45 degree angle of disc will eliminate chattering except under a combination of extraordinary conditions.

ANGLE PATTERN

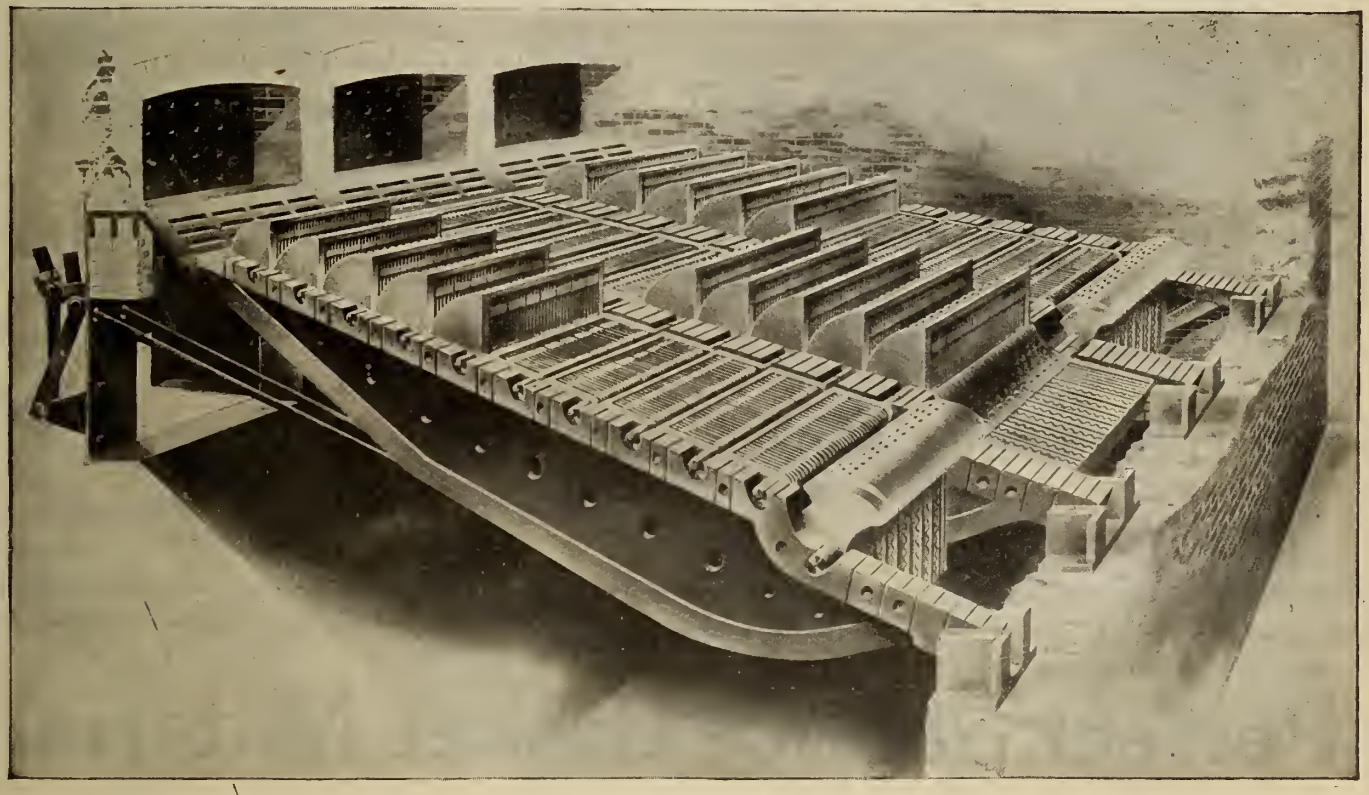
Files Stokers

Hand Operated



150% to 200% boiler ratings with Files Hand Stokers

Maximum ratings are being easily and economically obtained with Files Stokers—not for one day or two days, but continuously. Here are but a few reasons why many power plants using Files Stokers, are constantly enjoying the lowest operating expenses, the greatest steam pressures and have "jacked" their boiler capacity as high as 200 per cent. —safely and inexpensively.

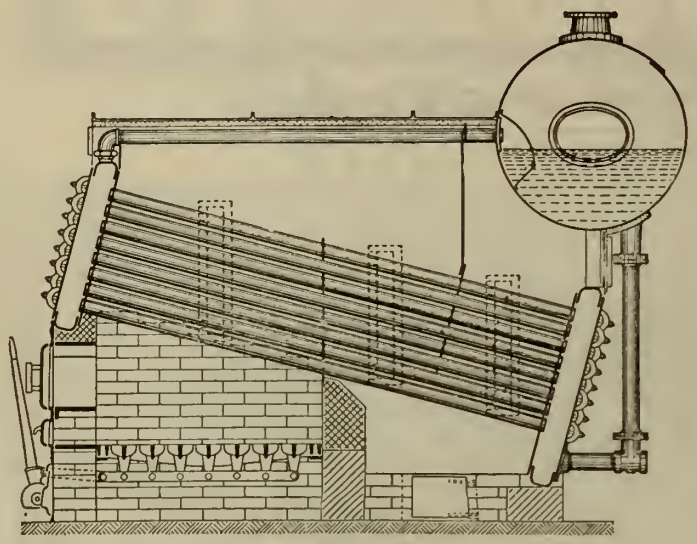
1.—Files Stokers insure complete and smokeless combustion.
2.—They maintain at all times a correct depth of fuel; clean and live fires.
3.—Air is constantly circulated and evenly distributed to all parts of the fire.
4.—All cleaning operations are instantly performed behind closed doors; there is no excessive inrush of cool air and resultant decrease in pressure, at any time.

If you want to increase the efficiency of your boilers, write for bulletin "C" explaining the details of construction and operation of this simple hand operated stoker.

Waterous

BRANTFORD, ONTARIO, CANADA

The Victory Heating Boiler



Is a water-tube boiler designed for heating, and is the safest boiler that can be used.

It has a steel case lined with asbestos and firebrick and requires no brick setting.

It may be shipped knocked down and taken into a building through ordinary doors.

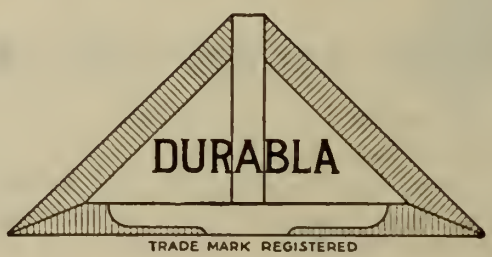
Perfect Service Gasket Material

Guaranteed to make a Tight Joint wherever a Permanent Gasket is required.

Place DURABLA in the next joints you make and be insured against a costly shutdown.



Strength; Goodness; Quality - these features distinguish Durabla Gaskets.

DURABLA Sheets can be rolled and unrolled; it never dries out or opens up.

DURABLA Compressed Asbestos Fibre Gasket Material is a guaranteed product that can be used as a standard for all Gasket work. DURABLA Gaskets make tight joints on Steam, Water, Oil, Ammonia and Acids at all temperatures and pressures.

DURABLA is not affected by vibration or condensation. It will not burn out, blow out or pulp at the points.

Let us send you a trial sample. Made in stock sizes 36 in. wide x 144 in. long, and 48 in. wide x 144 in. long, in thicknesses of 1-64, 1-32, 1-16, 3-32, 1-8.

Orders Filled Promptly.

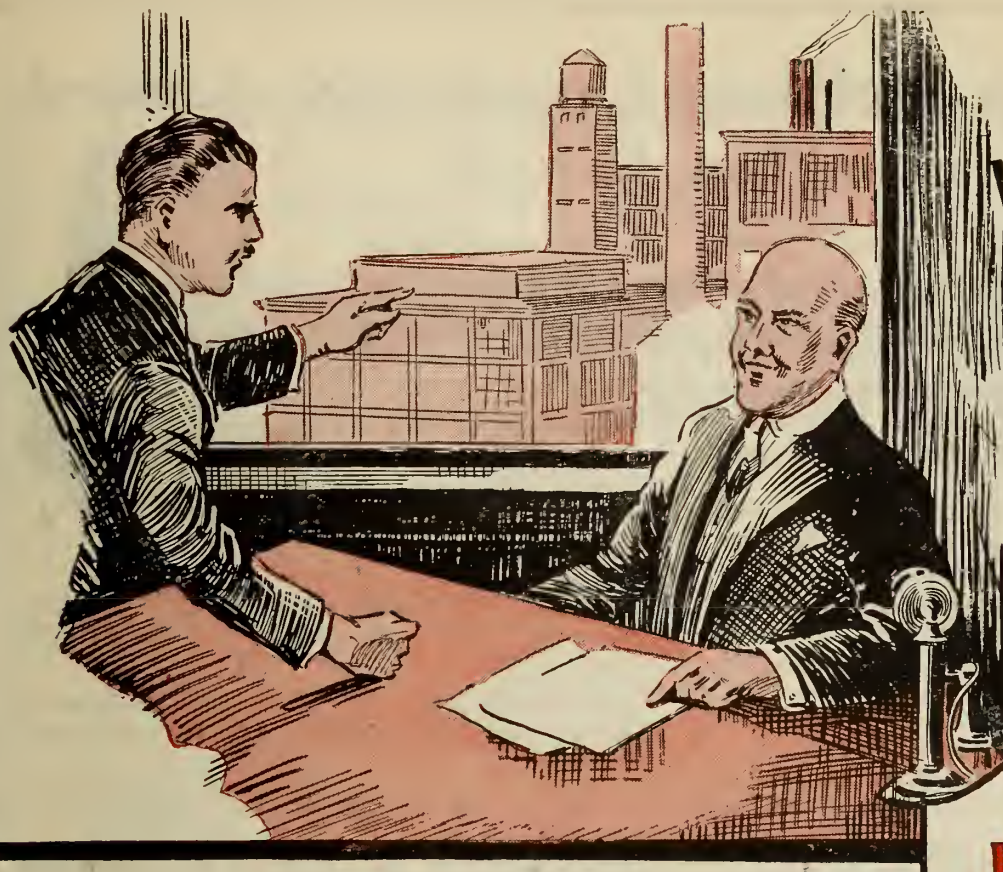
DURABLA



When the S.M. talks costs with the G.M.

When the wise General Manager asks his Sales Manager for a bigger share of the business, he explains how lessened factory production costs and a smooth working plant reflect themselves in uniform quality and low prices. That leads right up to the question of correct lubrication.

Correct lubrication with Imperial Lubricants is the one sure way of reducing operating expenses. There is a grade of Imperial Lubricants exactly suited to ***every bearing*** and ***every unit*** around industrial plants. All grades of Imperial Lubricants are scientifically tested and are of uniform high quality.

The service and advice of Imperial Lubrication Engineers is always available whenever needed. Write to 56 Church Street, Toronto.

Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd., Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Murphy Automatic Furnaces

New Parliament Building Heating Plant

MURPHY FURNACES fire the four boilers in the new Central Heating Plant which furnishes steam for the Dominion Parliament Buildings, Ottawa, as well as other government buildings.

Not alone in heating plants but in practically every line of industry Murphy Furnaces have made good and are being used—from hospital to industrial and central station service.

From every angle you approach the stoker question you will find the Murphy the logical choice for your stoker needs. Consider these points:

Standard in design and construction; replacements easily and quickly made; operates on natural draft; doubles the output of the plant without one penny for draft; adjustable while in operation; eliminates smoke loss; requires little attention; minimizes fuel cost and above all, the Murphy Furnace burns a wide variety of fuels.

Catalog H-M 10 will interest you. Ask for it.

RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

Turbine-Driven Blowers Must Be Rugged

THE DE LAVAL TURBINE-DRIVEN BLOWER unit shown is designed for gas plant work. It serves, however, to illustrate the care taken in designing De Laval apparatus to insure continuous, satisfactory service. Note the heavy construction of all parts, including the blower casing, also the forced lubrication with sight feed and the powerful and accurate speed governor, all features contributing to reliability in operation.

The same features are apparent in the design of all other De Laval apparatus, including turbine-driven generators, centrifugal pumps, blowers and compressors, speed-reducing gears, geared turbines for rope and belt drive, etc.

State class of apparatus in which you are interested and appropriate literature with special data will be supplied. Ask for Catalog F--100.

THE JOHN H. McGOWAN CO.
CINCINNATI, OHIO U.S.A.

Close Regulation

of Steam-Driven Boiler Feed Pumps

Hand control of steam-driven turbine pumps is not successful. The turbine needs a constant load for efficient operation. A sensitive, AUTOMATIC control is the only reliable way to maintain a constant load.

FISHER

Excess Pressure Governor

(Type 4)

is designed to render this accurate, automatic control.

It will maintain a fixed or overpressure in feed lines regardless of variation in steam pressure. It will do so under all conditions either on the ordinary plunger for steam-driven turbine type of boiler-feed pump. It will work satisfactorily whether supplying one or a battery or boilers.

It is recommended for use in conjunction with automatic feed water regulators.

The valve body is of our standard type of construction; the control is of the diaphragm actuated type.

Valve and seat rings are cast from our special formula, hard phosphor bronze which resists corrosion and wire-drawing.

Write for Bulletin No. 101. It contains full information about the Fisher Excess Pressure Governor and other Fisher Pump Governors.

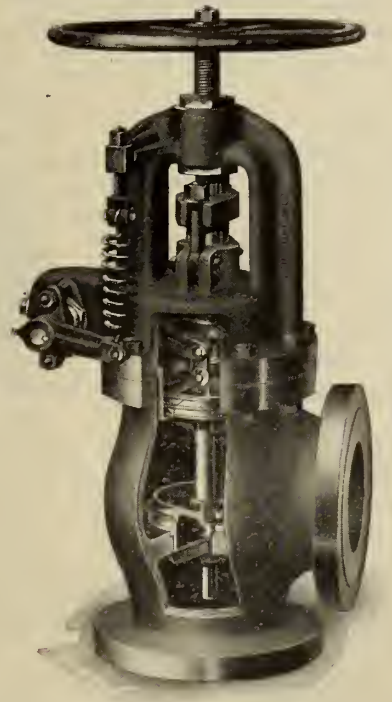
LUNKENHEIMER

Safety Non-Return Valves



Proper regard for the protection of life and property demands the installation of safety devices of established merit.

The Return Valve being second only to the Pop Valve as a boiler safety device, great care should be exercised in its selection.

Lunkenheimer Safety Non-return Valves have proved their reliability through many years of service and are warranted to perform all that is claimed for them.

They will automatically close and instantaneously cut out a boiler connected in battery when the pressure within the boiler suddenly drops below that in the header; they facilitate the operation of other boilers in battery, and they will enable the plant operatives to safely pursue their duties and will safeguard the life of a human being who may have occasion to enter a dead boiler should the regular stop valve fail or be opened through carelessness.

Lunkenheimer Safety Non-return Valves may be connected with the stem pointing vertically upward or horizontally.

All parts subjected to wear, including the disc and seat, are renewable and the seating surfaces are regrindable.

For service and reliability, specify "LUNKENHEIMER."

The Romance of the Advertising Pages

By F. A. McLean

LAYING aside for a moment the usual dollars and cents angle of advertising, have you ever stopped to consider the advertising pages of your magazine or trade paper from their human interest point of view?

Now an advertisement is just as much a news item as a notice in your home town paper that Sallie Jones was married in a red hat and that she is going to live in Podunk after the honeymoon, or that Bill Bailey lost three fingers last Friday while trying to clean the teeth of a buzz saw and swears that next time he tries it it won't be on a Friday.

The ads. tell you who, why, where, when and what and they come mighty close to us because they speak in a language that we know, the language of our hobby or our business.

Many of the brightest lights of our modern literary world are not too proud to write advertisements, or our famous artists to illustrate them. Where but in the advertising pages can we find finer examples of that almost extinct art of the etcher and the wood engraver?

Advertisements must compete for attention with the news pages, editorials, the stories, the articles and the pictures in the body of the magazine or the trade paper. Hence nothing is too good or too costly to illustrate the ads., which are often the finest examples of the best work of our photographers and photo engravers to-day.

So fine are some of these illustrations, and so beautifully worded and illuminated the texts, that they rank with the best in literature and art that have come down to us through the ages. In the colored inserts of our magazines we find reproduction of cakes, candies and other goodies, so resplendent and so natural that our mouths water, figures and faces of men and women so natural that we want to smile or cry when they do, look to see what they are looking at, gloves and clothing so realistic that we feel like picking them off the pages and putting them on, etc.

Let us imagine what we could do, you and I, if we had an Aladdin's Lamp and could bring all of the people, shops, machines and other products out of the pages of a single issue of Canadian Machinery and place them along a single city street.

Wouldn't it be a tremendously long street, and how interesting it would be to go down one side of this street and up the other, looking at all the wonderful array of people, shops and goods displayed? Just think how much we could probably learn with little or no trouble in a single trip.

Or let us shift the scene and let's pretend for a few minutes that we are back in the middle ages, and that each one of the ads. represents a town crier or a roadside stand. What an experience it would be to walk along listening to this great army of criers calling our attention to their masters' goods in all the varying tones, high, medium and low, which such a throng might be expected to use!

Or coming nearer home, let's go back a few years to the time we pitched marbles in the streets or played "Chaw Raw Beef" by the "Ole Swimmin' Hole," and imagine a circus coming to town—and such a circus as it would be if all the ads. could come to life and all their characters and products step down from the printed pages and form up in the grand parade!

How we, and other youthful "Captain Kidds," Jesse Jameses, and "Rain in the Faces" would have followed that parade and how quickly would the elephant, the clown, the painted lady and the fat man have been forgotten amidst such an array of wonders!

When you read the ads. you gain the pleasure and profit of clear thinking and store up in your memory for future use, for yourself or your friends, the endless supply of interesting and valuable information they contain.

Read the advertisements in your magazines, your newspapers, your trade journals—for the news they contain—for their educational value—for the life, vitality, art, wit and humor to be found in them—to raise your ideals and to guide you in your family and business affairs.

Here is what I found in a recent issue of CANADIAN MACHINERY:

Why I need a good die stock if I need one at all.

The story of a drill which worked for a piano company for two years without any trouble.

Some interesting facts about a town in Quebec.

How fast a hack saw should cut when in proper condition.

The solution of a brass working plant's cleaning problem.

What Canada's steel mills are making.

The clutch I should use for the place that's hard to get at, or where space is scarce.

The tale of a miller that keeps five die-sinkers busy and has been doing it for four long years.

The kind of machinery that should be used to grind parts with accuracy and despatch.

Vanadium and its effect on steel.

A metal that has mastered all other metals.

The kind of tools that are used in Canada's great logging camps.

The story of Mr. Punch and his fifteen hundred good tools.

The why and the wherefore of goggles in industrial plants.

A method by which drilling time may be cut from 20 to 2 minutes.

How motor truck makers grind their shafts.

A belt that will stand up under steam without going to pieces.

Why Gisholts are so successful.

One method that enabled a manufacturer to increase his production by 220 per cent.

A little detail in the construction of a wire fence that makes it stand up well.

The furnaces in which nichrome, the master of oxidation and heat, is made.

A conveyor belt that gives exceptional service because it is built like an automobile tire.

A means of cutting down overhead expense by using the right kind of hoisting and handling equipment, and many equally interesting and helpful pieces of news, human interest stories, etc.

Dart Union Pipe Couplings will not leak

Easily Connected

The Face and Seat being Ball-shaped permits easy and perfect connection even if pipes are out of alignment.

All threads are exact to standards and are clean and full.

Dart Unions are made in a variety of styles to fill all requirements.

Will Never Wear Out

Bronze meets Bronze at the joint, a feature that removes all possibility of deterioration at the vital part.

The Heavy Iron Parts will not stretch or pull apart, or become distorted when connecting up with a pipe line.

Canadian Association *of* Stationary Engineers

Incorporated May, 1887
Incorporated at Ottawa June, 1917

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?
If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.
The undersigned will be very pleased to give any further information required.

F. HARPER, President Grand Lodge.

This Bulletin Points a Way to Boiler-room Economy

The crying need of the world to-day is ECONOMY —and still MORE ECONOMY—coupled with greater efficiency in production.

There is a host of ways to arrive at the much desired result, of course.

One of them—a tremendous help in reducing boiler-room losses—is the Vulcan Soot Cleaner. It reduces stack temperature, increases steam capacity and production, and decreases fuel consumption.

Send for a Vulcan Bulletin and let it show you how and why Vulcan Soot Cleaners are a vital necessity in the modern boiler-room.

The Bulletin shown describes the Vulcan Soot Cleaner for Stirling boilers. Other Bulletins are: No. 541, for B. & W. boilers; No. 547, Wickes; No. 550, Connelly, Badenhausen and Erie City Vertical; No. 552, Edge Moor; No. 556, Keeler, Geary and Union; No. 534, Return Tubular.
Ask for the one for YOUR boilers.

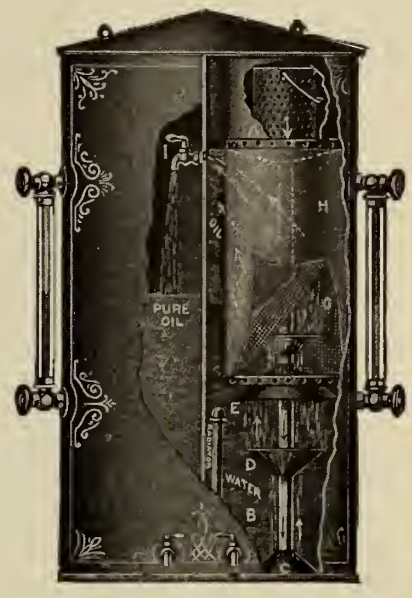
SIMS *Style A* OIL FILTER



Like All Sims Lines:

Thoroughly Dependable

AS THE function of an oil filter is to remove the impurities from the oil, three important features must be considered in the selection of this apparatus; first, means to be employed to remove the impurities; second, cost of filtering material; third, attention and time required for thorough cleaning. SIMS' STYLE "A" OIL FILTER MEETS the most exacting requirements in every respect and never fai'ls to prove an economical and efficient utility.

These filters are made in several sizes to meet various requirements, among them a small size designed for users of small power plants, gas or gasoline engines. Is there any further information you wish? We will be glad to answer any questions and furnish booklet containing a description of this thoroughly dependable oil filter.

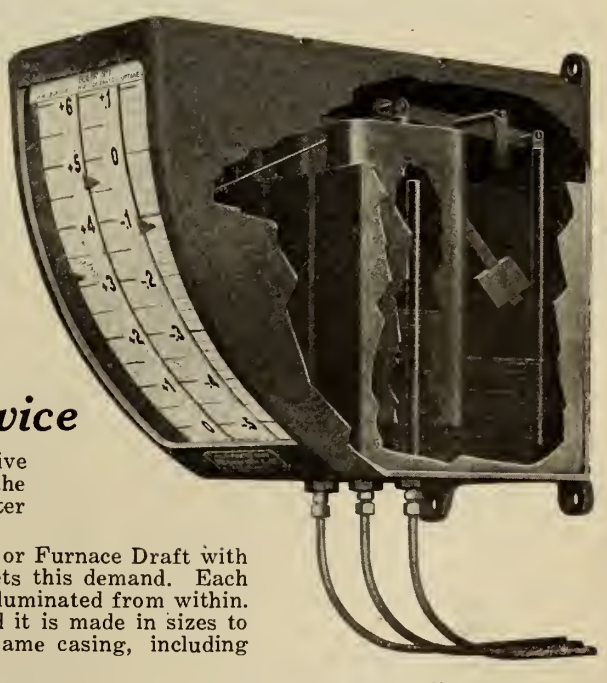
Multi-Pointer GAGES



Distinctly New and Valuable Device

These Gages were developed to supply a demand for a sensitive and accurate draft gage. The design is practically the same as the Fire Box Draft Indicator which has been in use on our Boiler Meter for several years.

With forced draft it is highly necessary to maintain the Fire Box or Furnace Draft with an accuracy of 0.01 inches of water. The Multi-Point Gage meets this demand. Each pointer has a 10-inch motion along the arc of a scale which is illuminated from within. The gage can be read with accuracy at a distance of 20 feet, and it is made in sizes to accommodate any required number of separate pointers in the same casing, including 2, 3, 4, 6, 8, 10 and 12 pointers.

There are two distinct types of casing used, one for wall mounting, known as Type P2, P3, etc., depending on the number of pointers, and the other design for meter board mounting, known as Type P2F, P3F, etc. The gage is so convenient and easily read that it will be developed to show high pressures, temperatures, stoker speeds and other factors, thus indicating on one instrument all secondary operating conditions.

This distinctly new gage is fully described in Bulletin No. 160—shall we send you a copy?

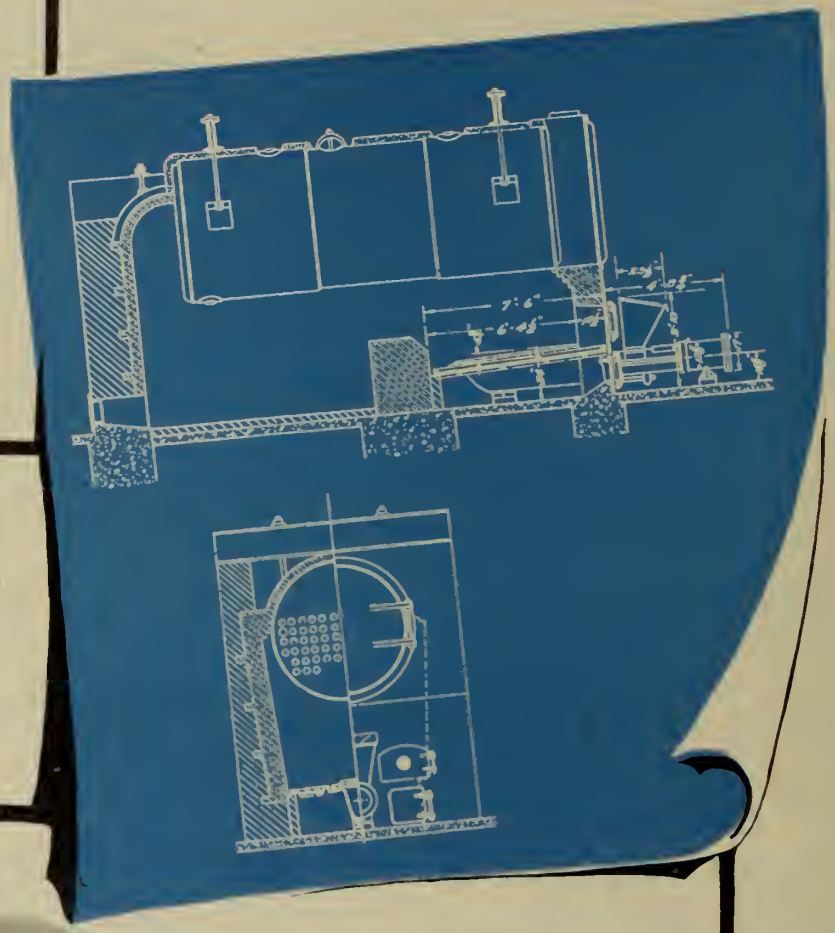
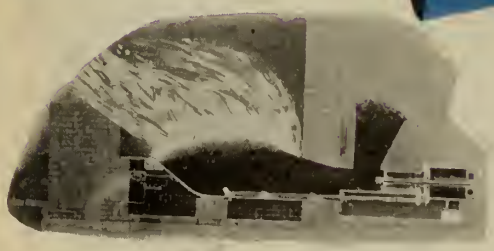
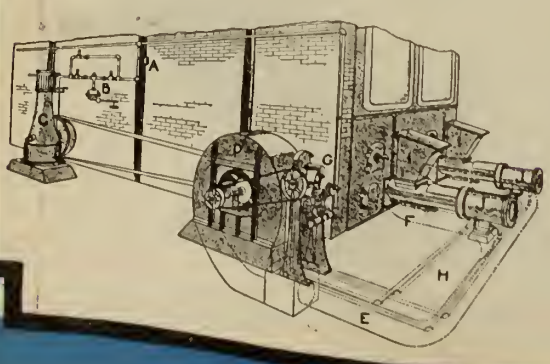
More Jones "Standard" Stokers Are Installed with R. T. Boilers Than All Other Makes of Stokers Combined





The vertical and longitudinal sections through the stoker and furnace (above) illustrate the "Standard" Stoker's operation. Note that the tuyere openings are above the fresh fuel in the retort, but below the fire. As the ram and pusher rod move the fuel through the retort, the volatiles are thoroughly distilled by the heat of the fire above and are entirely burned.

By the time the coal reaches the combustion zone it has become coked; so the released volatiles are burned in connection with coked coal. Naturally, this means efficient and smokeless combustion.



The drawing (opposite) shows the arrangement of the draft, blowing, and automatic-controlling mechanisms. The speed of the fan engine (C) is varied according to changes in the steam pressure by means of the fan engine regulator (B). This engine drives the blower to which is belted the Cole automatic valve. The Cole valve controls the steam supplied to the pistons (J) and this controls their rate of operation and the rate of fuel feed.

The air and fuel supply are thereby automatically controlled, so that an even steam pressure is maintained regardless of load fluctuations. Since the amount of coal supplied varies directly with the volume of air provided by the fan, high efficiencies are obtained at all times.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been re-organized as The Under-Feed Stoker Co., of Canada, Ltd., and the re-organization makes available for Canadian power users the extensive engineering resources of The Under-Feed Stoker Co. of America.

for Return Tubular Boilers

THREE thousand Return Tubular boilers are Jones equipped. More Jones Stokers are used for this service than all other makes of stokers combined. By an overwhelming majority the JONES "Standard" has been acclaimed the premier stoker for R. T. boilers. Why—?

Jones "Standard" Stokers

are simple, rugged, and are designed to meet the exact requirements of R. T. boiler installations. They are—

Built to fit 100 H.P. to 150 H.P. Units

Jones "Standard" Stokers installed throughout Canada with R.T. boilers have a proved record of 20 years of saving coal, saving labor, eliminating smoke, and increasing both boiler capacity and plant efficiency. Five hundred tests made during the last 10 years have proved that the saving in coal, over hand firing, ranges from 17.4 per cent. on Eastern coal up to 20.6 per cent. on low grade coal. With 12,000 B.T.U. coal the average saving has been 19.3 per cent.

Easily Installed in Existing Plants.

The blueprint (opposite) of a typical application shows how little excavation is required. Stokers can be easily and economically installed in existing plants practically without shutdown. No expensive ash or coal handling equipment is needed.

Maintenance Minimized.

In smaller stoker installations maintenance costs must be **extremely** low if the equipment is to pay big returns on the investment. The extreme simplicity, rugged construction, and accessibility of the "Standard" stoker insure **remarkably low maintenance.**

"Standard" stokers installed with R. T. Boilers are paying an average return in excess of 30 per cent. on the investment! If you burn two tons of coal per day it will pay you to find what "Standard" Stokers can accomplish by asking for a survey of your plant.

The Jones "Standard" gives the R. T. boiler plant relatively the same advantages that the Jones "A-C" brings to the field of high-duty firing. The same engineering service that has made the Jones "A-C" so highly successful is available for solving the firing problem of the plant operating R.T. boilers. Write for catalog showing installations with R.T. boilers.

The Economy of Working with Back Pressure

In Cases Where Steam at a Higher Temperature Than 212 Degrees, but Within Reasonable Limits is Required, a High Back Pressure on the Engine May be More Economical than Using Reduced Steam from the Boiler

By T. H. Fenner

A QUESTION that often arises and is the subject of much doubt among operating engineers, is that of the effect of carrying a high back pressure on the engine. This back pressure is required for the purpose of supplying steam to the radiation of the building, and sometimes for process work such as heating, dye tanks, lumber drying, etc. The question in the mind of the engineer is whether it is better to carry a higher back pressure and use the exhaust steam, or to supply the steam through a reducing valve direct from the boilers. The subject is one that deserves a little study.

Steam Per H. P. Hour

Suppose that the engine is of the single cylinder non-condensing type, and has a consumption of 30 lbs. steam per indicated horse power per hour. Now just what do we mean when we say that the engine has a consumption of 30 lbs. steam per I. H. P. per hour. Do we mean that it requires that weight of steam to perform the work done by the engine, or that the heat units contained in that quantity of steam are necessary for the production of the horse power delivered by the engine? Let us examine a horse power in the light of the heat units it contains. One horse power, we know, is the performance of 33,000 foot pounds of work in one minute. Now the first law of thermo dynamic tells us that each unit of heat requires for its production or gives up in its dissipation 778 foot pounds of work, and that heat and work are mutually convertible. This means that for each horse power there is required 42.416 B. T. U. per minute, or 2545 B. T. U. per hour. Now then if the steam is supplied to the engine at 100 lbs. gauge pressure, and exhausted at one lb. above atmospheric pressure, we can see what quantity of heat is contained in the steam, and what proportion of this heat is actually used by the engine. Steam at 100 lbs. gauge pressure contains 1188.7 heat units, and steam at one pound above atmospheric pressure contains 1152 heat units. That means that when the exhaust opens every pound of steam contained in the cylinder escapes into the atmosphere with 1152 of its 1118.7 heat units still available. Now if each pound of steam contains at its entry into the cylinder 1188.7 B.T.U., and the production of one horse power requires only 2545 B.T.U., it is evident that the heat equivalent we receive is only that contained in 2.13 lbs. of steam per hour. In other words there is enough heat in 2.13 pounds of steam at 100 lbs. gauge pressure to produce work at the rate of 33,000 foot lbs. per minute for one hour. Yet to do this work we have to pass through the engine we speak of no less than 30 lbs. weight of steam per hour, and we have available at the exhaust in each pound of steam 1152 heat units, or for each horse power the engine produces $1152 \times 30 = 34560$ heat units. If the engine is 100 horse power that means we throw away in exhaust 3,456,000 heat units per hour.

Heat and Temperature

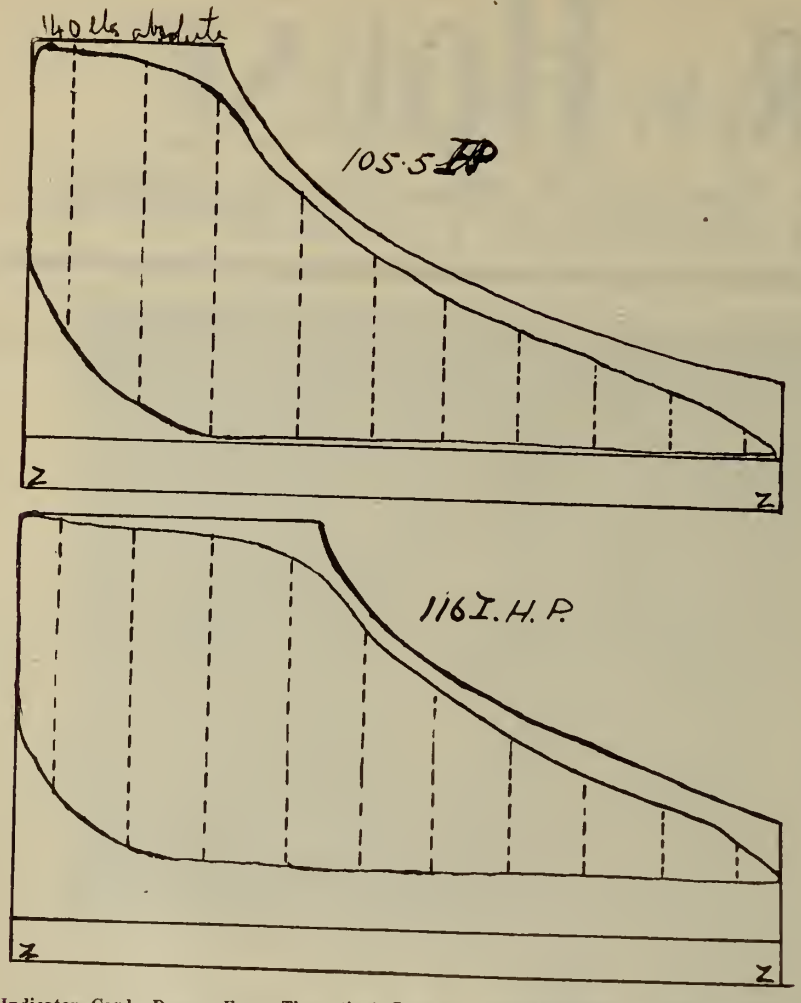
We have considered the heat available in the foregoing without reference to the temperature, but if we are going to see what possibilities the exhaust holds for us, we must examine it from the viewpoint of sensible heat. Sensible heat is temperature, and in the present state of human development, the use we can make of masses of heat depends entirely on the level of temperature that they are at. For instance, there is quite a large quantity of heat present in a field of ice, but it is at such a low level of temperature that with the heat engines we have available it is of no use to us. The same amount of heat, contained in a much less weight of steam, but at a much higher temperature level, would be of infinitely more use to us, as we could apply it to a steam engine piston or turbine rotor, and turn it into power. True, we should lose a very much larger percentage of it than we should make use of, but we could turn some of it to useful work. This is the effect of temperature. Now when we come to problems of heating such as the heating of a building, or the heating of water tanks, we have to consider the requirements from a temperature standpoint and not from that of heat alone. This applies more particularly to the question of heating lumber drying kilns, japan ovens, etc., where high temperature is a manufacturing necessity. For instance, the temperature of exhaust steam is always high enough for the ordinary heating of a building, and also for heating water by direct mixing, because the highest temperature obtainable applied to water at atmospheric pressure will not raise its temperature above 212 degrees. However, if you have lumber kilns or japan ovens for instance that require a temperature of say 250 to 300 degrees to perform the work within a specified time, the temperature of the heating medium must be raised accordingly. The same amount of heat could be supplied by exhaust steam at 212 degrees but it would take a longer application on account of its lower temperature.

Thus we see that there is a very great necessity to distinguish between sensible heat, or temperature, and total heat which is the sum of the sensible and latent heat, and represents the ultimate possible amount of heat available.

Heat Efficiency

In the engine we have been discussing, the steam is supplied at a temperature of 337.4 degrees Fahrenheit, and a latent heat of 880.4 B.T.U. the total heat in the steam above 32 degrees being 1188.7 B.T.U. This steam is expanded in the cylinder, giving up heat in work on the piston, and also losing some by radiation, etc., until it is exhausted at a temperature of 21 degrees, and a latent heat of 967.6 B.T.U. or a total heat above 32 degrees of 1152 B.T.U. We see then that while the temperature has dropped, the latent heat has increased. The total heat has of course decreased by the amount used by the engine.

The efficiency of any heat engine from a thermal point of view depends on the range of temperature, or temperature drop in the heat medium, measured on the absolute temperature scale. The greater the drop in temperature the greater the efficiency, the percent-



Indicator Cards Drawn From Theoretical Curve to Illustrate Effect of Back Pressure.

age of efficiency being calculated from the formula

$$\frac{\text{Heat received—Heat rejected} \times 100}{\text{Heat Received}} = \text{Useful Heat Percentage}$$

Putting this into figures we have, using absolute temperatures which are equal to Fahrenheit temperature plus 460

$$\frac{797.4—673 \times 100}{797.4} = 15.5 \text{ per cent}$$

The above is the thermal efficiency in the engine cylinder itself, and considering only the steam after it has entered the cylinder. That is we are not taking any acount of the heat put into the steam in the boiler. Now if we have feed water entering the boiler at 180 degrees F. we have put into each pound of steam at 100 lbs. gauge pressure 1008.4 heat units.

At 30 lbs. steam per I.H.P. per hour we are using ½ lb. steam per minute or 504.2 heat units. We have seen that one horse power is the equivalent of 2455 B.T.U. per hour or 42.416 B.T.U. per minute. Therefore we are getting in work only 42.4 divided by 504.2 or .084 x 100 = 8.4 per cent. of the heat put into the steam in the boiler.

Now if we can utilise the heat of the exhaust steam after it leaves the engine, we can then only charge the engine with the actual amount of the heat it uses, instead of the whole amount of steam that passes through it. This is a point that is not fully realised by a great many engineers. They will say that increasing the back pressure of the engine, means that for the same cut off there is less power, and in order to get the same power with the back pressure more steam must be used, that is a later cut off must be allowed. Now the point is this, that although more steam may pass through the engine, the engine actually only uses the same amount of steam to deliver a horse power, and the heat is still available at the exhaust for other purposes.

How It Works

Let us take an example, and work out the results from the indicator cards of an engine working under different conditions of back pressure. We will assume that the exhaust is needed for heating a building, and therefore the temperature of steam at atmospheric pressure will be ample. We will take as a typical case a small plant where the engine is of 100 horse power, steam, being supplied at 125 lbs. gauge, exhausting into the atmosphere or into the heating system as required. We will assume that a portion of the exhaust is used for heating the feed water from 50 degrees to 200 degrees. We are not concerned here with the boiler or furnace efficiency, that is we do not take into account how many heat units go into the furnace to produce the steam, but only the heat units contained in the steam as it leaves the boiler.

We will assume the engine to be 18 inches diameter, by 24 inches stroke, running at 60 revolutions per minute, with an initial pressure of 125 lbs. gauge and cutting off at about ¼ stroke. We can now construct an indicator card from these particulars, and obtain the theoretical expansion curve, and from this the probable actual performance curve. From this we can get the steam consumption with the cut off and exhaust at normal, and then see what effect increasing the back pressure will have.

With a mean effective pressure of 56 lbs. per square inch we get a horse power of 105.5, with a steam consumption as estimated from the indicator card of 21.7 lbs. per I.H.P. per hour. This is better than we would get from an actual engine of the dimensions given, but will do for the purpose we have in mind.

We have then put into the steam in the boiler, or into the boiler feed water to turn it into steam at the pressure required 1024.2 B.T.U. Exhausting at one pound gauge above atmosphere we have available 1152 heat units, but we have put 150 heat units into the feed water before it went into the boiler, and this must be subtracted from the heat available in the exhaust steam, or added on to the heat put into the feed water in the boiler. It comes to the same thing as far as the heat used by the engine goes, but for the sake of clearness it is perhaps better to include it in the heat delivered to the engine. We have then 1174 heat units in each pound of steam supplied to the engine, of which but 22 are used while passing through the engine.

Deducting the 150 heat units which we are going to use to raise the feed water temperature from 50 to 200, we have 1002 heat units at a temperature of 212 degrees available for heating purposes in every pound of steam. As we are using 21.7 lbs. steam per I.H.P. per hour, and developing 105 horse power, we have available 2278.5 lbs steam per hour. Multiplying this by the available heat in each pound of steam we have in actual heat units 2,283,057 per hour. If we are going to use the exhaust steam for heating a building by means of direct radiation, and can reckon on radiators giving off about 250 B.T.U. per square foot surface per hour, we will have enough heat, neglecting losses between the engine exhaust and the radiating surface to supply 9132 square feet of radiating surface, with steam at atmospheric pressure. Now let us see what would happen if we had to supply this amount of radiation direct from the boiler, without passing the steam through the engine on its way. We can assume that the steam is supplied from the same high pressure boiler, but passes through a

reducing valve before going to the heating surface. We will assume that the feed water is supplied to the boiler 180 degrees, the probable temperature of the returns from the heating system.

We have then put in each pound of steam in the boiler at 125 lbs. gauge, 1044 B.T.U., and the steam contains 1192.2 B.T.U. To supply 9132 square feet of radiation using 250 B.T.U. per square foot per hour, and neglecting losses between the boiler and the radiation, we shall require 1915 lbs. steam per hour. Now we have only to add 363.5 lbs. of steam to get our heating and 100 horse power as well, so it is evident that there is a considerable advantage in using exhaust steam, when it is available. As a matter of fact, the radiation losses will be greater between the boiler and the heating surface when live steam is used through reducing valve, as the steam will be at a higher temperature leaving the reducing valve and entering the steam main, than when exhaust steam is used. However we have not taken these losses into account in either case, but have assumed all the heat to be available at the radiating surfaces in the factory. This means that the engine has developed one horse power for about 3½ lbs. steam per hour.

Another Example

If we now consider a case where the steam is required for process work at a gauge pressure of 20 lbs. per square inch, such as in a paper machine, we wish to know whether it would be better to use a back pressure of 20 lbs. per square inch on the engine, or to run the engine with atmospheric exhaust, and supply the necessary steam through the reducing valve direct from the boiler. Let us see how much steam we would have to supply the engine with when working against this back pressure to get the same horse power.

We must increase the cut off in order to get the same mean effective pressure with the increased back pressure. Our mean effective pressure in the first case was 56 lbs. per square inch gauge, or 71 lbs. per square inch absolute, with a mean back pressure of 16 lbs absolute. We have to get the same mean effective pressure with an absolute back pressure of 35 lbs. or 20 lbs. gauge. This means that our absolute mean pressure supply plus the absolute back pressure will be 106 pounds absolute. This gives a ratio of mean to initial pressure of about .75, and the ratio of expansion corresponding to this will be about 2½. We can construct a theoretical curve using this as a base, and then draw what would be an approximate actual expansion curve, as we did before. Working this out we get a mean effective pressure of 62.4 and this gives an indicated horse power of 116. This is a little higher than we had at first, but it does not matter for purposes of comparison.

Taking the pressure at the point where release occurs, at about .9 of the stroke, we find it is 55 lbs. absolute. The weight of a cubic foot of steam at this pressure is .1285 lbs. and multiplying this by the volume of the cylinder multiplied by .9 we get the weight of steam per stroke.

Thus 1.5 x 1.5 x .7854 x 2 x .9 x .1285 = .398 lbs. This multiplied by 120 x 60 gives the pounds steam per hour, which comes to 2865.6 lbs., or a consumption of 24.7 lbs. per I.H.P. per hour. The exhaust pressure is 35 lbs. absolute, and the steam having expanded from 55 lbs absolute to 35 absolute without doing very much work after the exhaust port is opened, will have re-evaporated the moisture in the steam and may be considered as saturated steam at the final pressure. This contains 1166.8 B.T.U. per lb., which are available for heating. Multiplying this by the steam used per hour we have available 1166.8 x 2865.6 or 3,343,588.-08 B.T.U.

Now if we again consider that we take 150 B.T.U. from each pound of exhaust steam to heat the feed water to 200 degrees, we will have 2,913,742 B. T. U. to go to the machine.

Comparing again the steam we should have to supply for the same amount of heat units direct from the boiler we divide the total heat of steam at 125 lbs. gauge into the heat units required, neglecting losses as we have done all along. This shows that we shall require 2444 lbs. steam per hour for heating alone. Subtracting this amount from that required for driving the engine and heating as well we get 2865.6 less 2444 which leaves 421.6 lbs. per hour, for driving the engine, and this divided by 116 gives us 3.64 lbs. per I.H.P. per hour, which is nearly the same as before.

Comparing the Fuel Consumption

If we now consider these results in the light of fuel consumption, we shall have a good basis of comparison. In the first case we have the engine developing 105.5 horse power and using 2278.5 lbs. steam, supplying the heating surface with exhaust. We see that to supply the same amount of heating surface with direct steam we shall require 1915 lbs. steam. If we assume that each lb. of coal evaporates 9 lbs. water actually, we shal require to burn for driving the engine and heating the building 253.1 lbs. coal per hour. To heat the building alone would require 212.7 lbs. coal per hour, so that for 41 lbs. coal per hour more we get our power in addition to the heat.

In the second case we have 116 horse power from the engine with a back pressure of 20 lbs. gauge, and are supplying heat for manufacturing process with the exhaust. The steam consumption under these conditions is 2865.6 lbs. per hour, and expressed in coal consumption we have 318.4 lbs. coal per hour. To supply the same amount of heat to the machine without any power we have to use 2444 lbs. steam per hour, and this in terms of coal is 271.5 lbs per hour. Thus for 47 lbs. coal more we get our power.

The foregoing is an attempt to show in a simple clear manner the economy resulting from the use of back pressure on an engine for raising the exhaust temperature, where heating is required at a higher temperature than 212 degrees. It is of course to be understood that each case must be judged on its merits, but the idea that running an engine with a high back pressure must necessarily be uneconomical is wrong, and every engineer should understand clearly the principle involved. The engine must only be charged with the actual amount of heat that it uses to develop the horse power when the balance of the heat is utilised in some other process. Only when the exhaust is wasted, or ejected to the condenser, can the total amount of steam consumption be charged up to the engine.

CATALOGUES

The Pyramid Iron Products Corporation, 2 Rector Street, New York, have issued a bulletin describing their "Pyramid" grates, specially designed for the burning of the lower grades of anthracite screenings, silt, culm and lignite. The design of the bar is such that there is no direct vertical blast of air through the coal, but the air is delivered horizontally through the fuel bed. This tends to prevent the small stuff being blown off the bars. It is claimed that the bars can be made in comparatively light weights, without danger of warping or burning.

The Vasils Steam Systems Co., Washington, D.C., are putting on the market a stoker designed for hand or automatic operation, with dumping grates and a hopper feed, and have issued a bulletin describing and illustrating the apparatus. It can be changed from hand operation to automatic operation by fitting a shaft across the boiler front, and very successful results are claimed to have bee obtained from it.

Bernard H. Prack, architect and engineer, Hamilton, has issued a bulletin entitled Boiler House Economy, one of a series on the subject of power plant design. In this bulletin the features of a large number of power houses designed by the author are described, and their relation to the economical operation of the plants pointed out. A list of some of the large clients of the author is included, the object of the booklet being to show the importance of proper design of power plants.

We have received from the Plant Engineering and Equipment Co., their catalogue describing steam specialities, including Pecco steam trap gauges, Corliss Valve Steam Traps, Turbo Blowers, heating specialties, etc. The various specialties are illustrated, and there is a table on the back page showing flow of steam at various pressures, and factors for pressure drop in steam per 1000 feet. The address is 192 Broadway, N. Y.

Straight Flow High Lift Poppet Valve Engine

The Feature of this Engine is the Very Small High Lift Nozzle Disk Valve—This Enables a Very Small Amount of Clearance Being Used, Giving High Compression and Temperature

By J. Stumpf

LOSSES in steam engines are due to cylinder condensation, clearance space, throttling, friction, leakage, heat radiation, heat conduction and imperfect expansion. It is claimed that some of these losses are reduced in the engine about to be described.

The most characteristic element in this straight-flow, or "uniflow" steam engine cylinder shown in Fig. 1, is the very small high-lift nozzle-disk valve employed therein. It became possible to give this valve such small dimensions through the employment of a valve-gear shaft running at twice the speed of the main shaft. For an average cut-off of 10 per cent. the eccentric motion with the camshaft running at a speed of the main shaft will give a maximum valve lift of h', while a valve lift four times as great is obtained with a double speed of rotation by means of which the central angle is doubled. Because of this a double-seated valve of 200 mm. (7.87 in.) diameter can be replaced by a disk valve 100 mm. (3.93 in.) in diameter, with a corresponding reduction of clearance space and cylinder condensation area.

The valve motion is regulated from a layshaft running at twice the speed of the engine shaft by means of a cam, of which the lift and lead are regulated by means of a shaft governor, Fig. 3. The motion of the eccentric is transmitted to the disk valve by means of an intermediate lever and an angular lever located in the casing. The intermediate lever is made up in the form of an eccentric ring set on a rigid eccentric disk running at the same speed as the main engine shaft. The arrangement is such that when the main eccentric takes the position corresponding to the maximum valve lift the auxiliary eccentric on the second lay shaft is in the opposite extreme position, thus producing an increased valve lift. When the main eccentric occupies the next similar position, the auxiliary eccentric reaches the opposite location so that the actions of the two eccentrics have to be subtracted from each other. The resultant valve motions are shown again in Fig. 4, by means of the Zeuner polar diagram, which emphasizes the extent of the valve opening resulting from the fact that the valve shaft runs at twice the speed of the main engine, and also shows the absence of all necessary motion of the valve in the opposite position. The linear lead remains the same. As a result of this arrangement it becomes possible to use small valves with a total clearance in the cylinder of between ¾ and 1 per cent. and with an extremely small area of cylinder condensation surfaces. If it be assumed that these condensation surfaces are ideally small, that is, equal to twice the cross-section of the cylinder, it would appear that the additional cylinder condensation surface entailed by the use of the small high-lift nozzle-disk valve is only from 3 to 5 per cent. thereof. It is claimed that this arrangement affects the reduction of cylinder condensation area in a most favorable manner, which is generally low in straight-flow steam engines. As regards this latter, reference is made to tests carried out on a straight-flow cylinder by Professor Nagel, at the Dresden Polytechnic Institute. (The temperature diagram of these tests is reproduced in Fig. 5.) In that case only the cylinder head was provided with a jacket and the engine was operated with an extremely good vacuum. Notwithstanding this fact, during the exhaust stroke the temperature, as determined by a thermometer in the head, did not fall below 100 deg. Cent. Because of the extensive temperature drop during the exhaust and because of the appearance of a very considerable percentage of moisture in the steam (as high as 20 per cent), the heat of the steam in the head was caused to flow with great energy into the rest of the steam still present in the cylinder. Of this heat practically none is lost in the exhaust. The piston on its return stroke collects this overflow of heat by the compression of the remainder of steam to something like 2.5 to 3 atmos., corresponding to a clearance of about 3.3 per cent. The next compression occurs practically along the saturation adiabatic curve, which is joined at an angle by the superheat adiabatic curve and gives the startlingly high compression and temperature of 510 deg. Cent. At the end of the admission the superheat expansion adiabatic curve joins on, and then abruptly the saturation adiabatic curve. The latter, in its last stages, is raised by the setting up of the flow of heat referred to above, until the exhaust again causes temperature drop, which

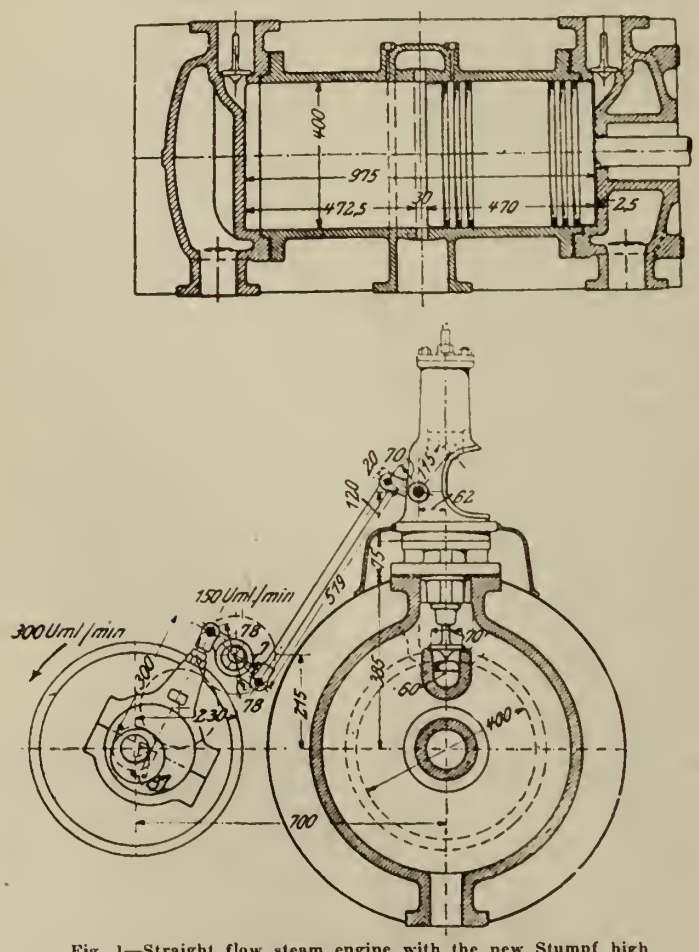


Fig. 1—Straight flow steam engine with the new Stumpf high lift nozzle disc valve.

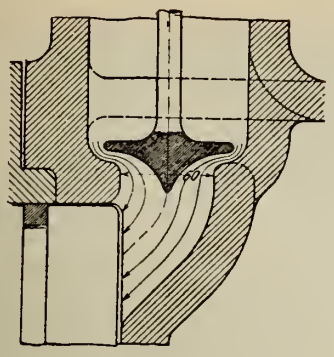
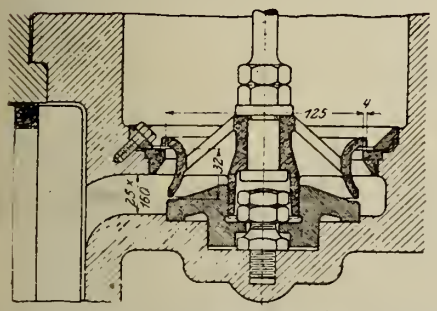
Fig. 3—Valve gear drive.





Comparison of two kinds of engine valves with same area of steam passage. Above, high-lift nozzle disc valve.—Below, double seated valve.

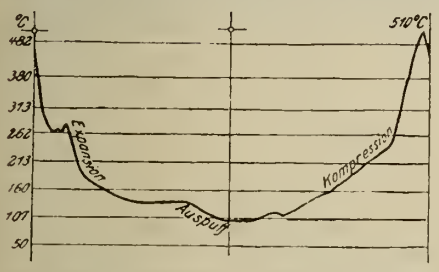


Fig. 5 Temperature Diagram
(*Auspuff* = exhaust)

is, however, immediately opposed by the flow of heat from the cylinder-head steam.

However, when, by the use of the high-lift nozzle-disk valve the clearance is reduced from 3.3 per cent to something between ¾ and 1 per cent., the compression end pressure is raised correspondingly, resulting in a rise of compression and temperature of between 900 and 1000 deg. cent. In this connection Professor Nagel has established the surprising fact that in the same manner a final compression temperature with saturated steam is obtained 100 deg. Cent higher than with superheated steam, which is probably attributable to the higher heat conductivity of saturated steam.

If, however, these favorable heat conditions are combined with small cylinder condensation surfaces as becomes possible with the new high-lift nozzle-disk valve it may be ultimately possible to do away with cylinder condensation entirely.

The upper part of Fig. 6 shows the new high-lift nozzle-disk valve operated by a lay shaft running at twice the speed of the main shaft, as compared with the double-seated valve of standard design below it, and also their relative dimensions. It is also claimed that

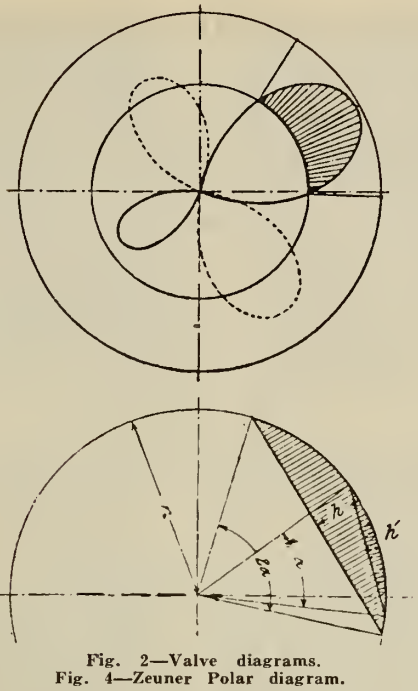

Fig. 2—Valve diagrams.
Fig. 4—Zeuner Polar diagram.

the new valve is considerably simpler and cheaper both in manufacture and in installation. (Zeitschrift des Vereines Deutcher Ingenieure.)

A Few Days Ago a generator under test at the Canadian General Electric Co., Peterboro, Ont., exploded, causing considerable damage, and one death. Since that time the matter has been gone into carefully and an official estimate places the damage at about $150,000. The generator, valued at over $50,0000, is wrecked, a number of other generators being built in its vicinity are seriously damaged, and several machines and the instruments and records of the test department are destroyed. The generator, engineers say, was being operated at 100 per cent. over speed, about 1,000 revolutions a minute, when the accident occurred. This means that a given point on the rotor was travelling at the rate of about four miles a minute.

Chatham, Ont.—Fuel oil is now being used with success at the Corhill Bros. brick plant. The new burner used is the result of seven year's experimenting and a combination of steam and fuel oil is employed. The bricks. produced are said to be of a more uniform quality.

The Toronto, Ontario, Canada, office of the Independent Pneumatic Tool Company has been removed from 32 Front Street West, to No. 163 Dufferin Street, Toronto. This new location will give the Independent Pneumatic Tool Company larger space and increased facilities for carrying a complete stock of Thor Pneumatic Tools, Electric Tools, Spare Parts and Accessories. The Toronto Office will remain in charge of Mr. William McCrae.

BOOK REVIEW

We have received from the Van Norstrand Company of New York, three books dealing with heat and temperature. The author is R. Royds, M. Sc., A. M. I. Mech., who is head of the motive power Engineering Department in the Dundee (Scotland) Technical College. The books are entitled, "Heat Transmission Boiler Condensers, and Evaporators." "The Measurement of Steady and Fluctuating Temperatures," and "Heat Transmission by Radiation, Conduction and Convection."

The first book is divided into three departments, boilers, condensers, and evaporators. The first part goes very thoroughly into the heat transmission from furnace to water in the boiler, and gives the results of tests, and a very thoroughly analysis of all the conditions relating thereto. This chapter contains 100 pages, and is clearly illustrated by charts and diagrams. The second division of the book goes into the question of condensing steam, and contains a very thorough exposition of the theory and practice of condensing, and all the latest knowledge and experiments along this line of study. The chapter on evaporating should be of special value to those interested in sugar making and allied industries. There are several pages of tables and data.

The work on "Heat Transmission by Radiation," etc., takes up all the work that has been done along these lines by various authorities and the results of experiments made by the author himself. This work leads up to the one just mentioned, and the two together form a very complete and valuable compendium of the subject of heat transmission. The various diagrams and charts are very clear, and the calculations have been worked out in a way that makes them very easily followed by the reader.

The third book is a very complete review of the various instruments in use for measuring temperature, and is very profusely illustrated. To the large number of people who invariably think of a thermometer as a glass tube filled with mercury this little book would open up a world of wonder, while to the practical engineer who has a wider knowledge of heat measuring instruments than the layman, the book will be found very valuable. The three together comprise a real little library on a highly important subject. They should be especially useful as text books in technical colleges and universities as well as to the practical and consulting engineering profession. The price of three volumes is $13.50, or $4 for part 1 and $4.50 each for the volumes on heat transmssion.

ANNOUNCEMENT

Peacock Bros., Ltd., Montreal, have been appointed district representatives for the sale of Cope's Pump Governors, in the Province of Quebec.

The Power Plant of the Eastern Car Company

In this Article, our Maritime Provinces Representative Has Described Another Large Power Plant in Nova Scotia. This Company Operates One of the Leading Industries in the Maritime Provinces, and the Power Plant is an Interesting One

By J. A. McGillivray

THE PLANT of the Eastern Car Company, situated on the East River of Pictou County, marks one of the milestones of industrial development in the Maritime Provinces, in recent years. Built entirely of steel and concrete, and equipped with the most up-to-date machinery for freight car building, having a rated capacity of 25 cars per day, and a record to its credit of 35 cars per day (140 per cent.,) its activities have not been confined entirely to freight car building, but it has undertaken and profitably completed such work as motor trucks, snow ploughs, locomotive repairs, steel pit boxes, munition making and steel pressing for steel ship building.

There is in connection with the car plant a wheel foundry, operated at present under lease by the Dominion Wheel Foundry Co., having a capacity of 500 car wheels per day, as well as other varieties of heavy castings.

The plant is a subsidiary of the Nova Scotia Steel Company, now forming one of the extensive holdings of the British Empire Steel Company.

The situation of the plant is ideal, being located on tide water. The lumber required for manufacturing purposes can be landed in its own yards from the parent company's own ships. To facilitate this the East River was dredged from Pictou Landing to Trenton to accommodate ships of large tonnage. A system of locks were built just below the company's holdings, and a natural basin at the site of the company's holdings forms an ideal anchorage. The East River waters are maintained at high tide level by the lock gates. The steel for manufacturing purposes is supplied mainly from the parent company's steel mills, whose yards adjoin those of the car plant. The coal and coke is supplied from the company's own mines, two miles distant, so it may truthfully be stated that the car plant is ideally situated. Not only this, but the parent company's shipyard is located in the yards of the Car Company, who supply light and power as well as pressed steel and woodwork to that industry.

The shipyards build steel ships of from 3,000 to 5,000 tons capacity, and have at present on the ways an almost completed steel yacht that represents the best and most modern in ship construction in America.

The most interesting part of this company's equipment to engineers is the power plant, which supplies light and power to the car plant, shipyards and steel mills of the parent company.

The central power plant of 2,400 B. H.P. tabulated consists of the following equipment, which will be described in order given.

The Central Power Plant —Fuel Handling

1 track hopper, capacity 40 tons.

1 coal breaker, (Brown Mach. Co.) 40 tons per hour.

1 Gravity bucket conveyor (Brown Mach. Co.) 40 tons per hour.

1 40 H.P. General Electric three-phase, 60 cycle, A.C. motor, connected to coal breaker and bucket loader.

1 15 H.P. General Electric three-phase, 60 cycle A.C. motor, driving gravity bucket conveyor.

1 400 ton concrete lined steel bunker for coal storage, over boilers.

1 Sturtevant Blower System for delivering shavings, sawdust and wood refuse to boilers.

1 concrete storage vault for storage of shavings; capacity, 18,000 cubic feet.

Boilers

Boiler room, 110'x40'x46' high to eaves.

4 Edge Moore "all steel" water tube boilers, having a combined heating surface of 24,000 square feet, and equipped with Foster super-heaters having a capacity of 125 degrees superheat.

Stokers

4 Green chain grate stokers, 110 square feet surface each.

Breeching

1 steel breeching, extending over the boiler and terminating in a concrete chimney.

Chimney

1 concrete chimney, (Weber), 175 ft. above the grates, 8 feet diameter.

Main Header

1 16 inch ex. h. steel, 70 feet long, anchored at centre with outlets at each end and separate branches to turbines.

Feed Pumps

2 Standard Weir pumps, size 14 in. x 10 in. x 24 in. stroke, capacity 88,000 lbs. per hour, at 70 per cent. efficiency, against 450 feet head.

1 4-in. Venture Meter, (Builders' Iron Foundry Co.)

1 5,000-H.P. Cochrane open feed water heater.

The boilers are equipped with Reliance high and low water alarms inside of Reliance Standard Safety water column. Ashton spring pop safety valves, 2½ in. Pemburthy Injectors, Locke damper regulators, Ellison differential draft gauges, standard steam gauges, steam pressure and steam temperature recording gauges. Feed water temperature recording gauges, Crane non-return valves on both main and auxiliary steam headers. Diamond soot blowers are installed. They are of the six element type with the latest standard jets.

Turbine and Engine Room

110 feet by 60 feet by 25 feet at eaves. Separated from boiler room by concrete wall with standard safety fire doors, contains the following:

Turbine Floor

Pump No. 3. 1 Vert. 2½ inch Worthington turbo pump, direct connected to 10 h.p. G. E. motor, used for pumping out the pump pit.

The Boilers

The boilers burn both coal and shavings, the coal being fed to the grates in the ordinary way. The shavings being introduced through openings in the top of the Dutch ovens, these openings are admittedly a source of excess air and care is taken to seal them when burning coal alone.

The furnaces as originally constructed were the Standard Green type for burning bituminous slack coal, but in order to get good rating when using a very low grade of fuel it was deemed advisable to change the ignition arches to what is known as the sealflex arch, patented by the Green Engineering Company. This change was made when the stokers were being repaired.

During tests made with low grade fuel the best results were obtained with a grate speed of 4 in. per min. and a fuel bed of 4½ inches in thickness. At higher speeds the fire would carry away from the grate, while if the fuel bed was reduced the fire burned off short and if thickened over 4 in. green coal carried over. So after many experiments a standard rule was adopted, based on the results of these experiments. A variety of tests were conducted with a view to getting the best grate speed and fuel bed thickness to operate at approximately 150 per cent. capacity. The most satisfactory of these results are given here.

The boilers are operated at approximately 150 per cent. of rating, and are 600 h.p. commercial rating. They are of the straight tube type. The tubes have an incline to the rear, and being 15 tubes high and 20 wide, with 4 inch tubes 18 feet long, and are vertically baffled. The water legs are forged steel.

The drums are 36 inch diameter, 3 drums to a unit and are bolted to the water legs instead of riveted. A copper grumet on the bolt, which is tapered, makes the job tight. The working pressure is 200 lbs per square inch, the steam being superheated to 125 degrees Fah. All the steam generated passes through the superheater, there is no mixing of steam and no provision made for by passing the superheater, so if one of the

Arrangement of water back.

elements gives out the boiler must be closed down. However, this has been known to occur but once since the installation of the plant, and was due primarily to insufficient expanding of the superheater tubes into their header. After the superheater tubes were properly rolled there was no further trouble from that source.

The bridgewalls are supported by a water back made of 1 inch Ex. heavy pipe as shown in sketch. In some installation of the type of boiler the water cask is connected to the water space of the boiler, and thus becomes part of the heating surface. This type is called the high pressure water back.

The grate surface is 110 square feet.

making the ratio $\frac{\text{H. S.}}{\text{G. S}} = 54..54$. The

average efficiency of operation for the boiler, furnace and grate is normally 70 per cent,, this varies, of course, up and down with the conditions, being about 65 per cent. on the night load and 75 per cent on the day load.

The boilers are connected to the main header by long crane bends. The connections are 8 inch, connecting into a 16 inch steel header, which is anchored at the centre and free to expand both ways. The steam header is fitted with valves so that any section can be cut out without interruption to service, and the main and auxiliary headers are so cross-connected that steam can be had from either for any machine or any auxiliary so long as there is one boiler under steam. The feed lines are also so connected that the pumps can feed the boilers through the injector lines, and vice versa, and should the city water pressure fail for any reason, the feed pumps or injectors can instantly be connected to the company's 300,000 gallon reservoir.

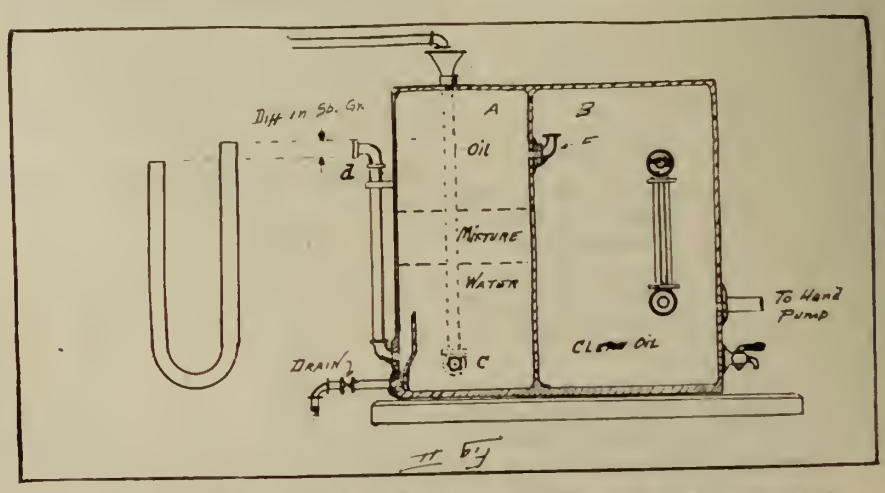
The feed water is supplied to the boilers at a temperature of 200 degrees Fah. to 210 degrees Fah. The overflow from the water backs at 90 degrees and the cooling water from the compressors at 90 degrees supply the feed heater with make-up water. The heater also receives the returns from the vacuum system as well as the condensate from the turbines.

The installation of steam soot blowers marked a vast improvement over the hand method both as a labor saver and an efficient cleaner. It was found that the hand method resulted invariably in banking the soot at the far side of the tubes instead of clearing it out entirely, whereas the mechanical blowers clean the soot off all the tubes almost 100 per cent. clean, except the two bottom rows, where the deposit (commonly referred to as birdsnesting) must be knocked off from time to time with a bar. The fireman showed me a nifty rig he fitted up for the purpose and it certainly did have some merit. It was made of 1 inch pipe reduced about the middle of its length to ¾ inch, and at three quarters of its length to ⅜ inch, with the end turned up. This he would connect to the compressed air hose and work it from the inspection door at the side, blowing up between the bottom rows of tubes and at the same time poking the nozzle into the deposits and dislodging them. Of course at week ends the tubes would be scraped clean.

This device had another use that should be mentioned. The fireman used to blow the accumulation of soot that forms on the bridgewall off every night and always had a clean bridgewall instead of a big sloping bank that we usually see, reaching clear to the bottom row of tubes, with the result that when it comes to be cleaned part of the bridgewall is liable to come with it.

The Engine Room

No. 1 Turbine is a 730 K.W. Curtis, built at Lynn, Mass., 3,600 R.P.M., of the Bleeder type. The bleeder is used in winter months for steam extracting from between the stages for shop heating. When the turbine is fully loaded 35,000 lbs. of steam per hour can be extracted from the first stage at a pressure of 5 lbs. gauge. The bleeder line (12 inch), is connected into the 24 inch heating main, with a suitable check valve between the turbine and the H.M., located in the 12 inch bleeder line, close to the turbine, at a predetermined pressure in the H.M., which may be anywhere between 0 and 5 lbs. The bleeder connection is automatically closed off and where the pressure falls off the bleeder is again automatically put into service. The turbine is a two-stage, using steam at 175 lbs. gauge superheated 100 degrees Fah. at the turbine inlet. The steam main is 5 inch, the water rate of the machine is guaranteed at 16 lbs per K.W.H. (When the pressure in the condenser is 2 lbs. absolute), the machine is fully loaded. Normally the vacuum is 29 inches or ½ lb. abs. in the condenser.



Description of Operation—Oil and water is piped to funnel and enters compartment (A) at bottom and displaces equal volume. Oil flows at (E) and water at (D), the mixture separating at (C), the oil floating to the top. The U tube shown at left illustrates the principle of operation.

The turbine and generator are coupled together by a solid coupling. There being three bearings, the packing on the shaft is of the labyrinth type steam sealed at a pressure of 10 lbs per square inch. The oil is supplied under pressure of 12 lbs per square inch by a gear pump driven from the main shaft. The cooling is accomplished by circulating water through a coil laid in the bearing linings. The oil reservoir contains 30 gals. The normal temperature of the oil is 145 degrees Fah. to 150 degrees.

The turbine is connected to the condenser by a corrugated copper expansion joint 30 inches in diameter. The condenser has a cooling surface of 1600 square feet, (a little over 2 square feet per K. W..H.) The condensate is discharged to the feedwater heater by a Terry steam turbine driven Worthington pump, size 2 inch discharge. The air and vapor is drawn from the condenser by a 10 inch by 12 inch by 10 inch Blake-Knowles dry vacuum pump, (speed 100 R.P.M.)

The generator is 3 phase, 60 cycles, 3600 R.P.M., 600 V-903 amps, 80 P.F. with a separate exciter. The cooling air for all the generators is conducted from the roof of the building through a duct having an area of 20 square feet. The air being forced through the ventilating spaces of the machines by fans mounted on the revolving field, and being discharged through a separate duct into the basement.

Turbo Gen. No. 2

This turbine is a mixed pressure Curtis type, which can be operated either as a straight high pressure condensing unit, low pressure cond. or mixed pressure.

There are two separate steam lines to the machine, One is a 6 inch high pressure (175 lbs gauge) the other a low pressure, about (15 lbs abs.) The capacity of the machine is 750 K.W. and speed 3600 R.P.M. built at Schenectady, N.Y., by the Gen. Eelect. Co.

This machine will develop its rated load (750) K. W. on low pressure steam, 15 lbs., at the throttle and a condenser pressure of 2 lbs. abs. with a steam cons. of 34 lbs, per K. W. H. As there is available in summer months quite a large quantity of exhaust steam over and above the feed heater requirements, the mixed pressure machine is operated on mixed pressure. The governor operates the valve gear by a cam that causes the L.P. admission valve to open full before the H. P. valve opens. Thus the full benefit of the L.P. steam is realized before any H.P. steam is admitted. If there is sufficient L.P. steam to carry the load the H. P. valves will not be opened. But if the supply of L. P. falls short of the requirements, the turbine governor continues to drop until the live steam is admitted to the turbine.

So that the vacuum won't reach back into the exhaust lines when the L. P. steam falls off, there is a Cochran multiflow valve placed in the line close to the turbine, which closes off communication between the low pressure nozzles and the exhaust lines. This prevents an inrush of air to the condenser impairing the vacuum and also prevents oil being sucked into the condenser and consequent polution of the feed water.

The generator, condenser and auxiliaries are practically the same as No. 1 machine, except that they are larger on account of the machine being run as a low or mixed pressure unit. The dry vac. pump is 10x20x10 inches, speed is 100 R.P.M. The wet pump is 2½ discharge and the condenser 3000 square feet, cooling surface, or 4 square feet per K.W.

Turbo Gen. No. 3

A H.P. non-cond. Westinghouse 750 K.W., 3600 R.P.M., connected to 750 K.W. generator, 3 phase, 60 cycle, 600 V-903 amps., with direct connected exciter.

This turbine is run non-condensing in the winter months. The exhaust steam being used for shop heating and kiln drying of lumber.

Turbo No. 4

A 125 K.V.A. non-condenser Terry steam turbine connected to a Crocker-Wheeler generator, 3 phase, 60 cycle, 1800 R.P.M., 600 V, is used for a standby set for lighting and small loads at week-ends. This machine can be started up and put on the S. B. in an emergency in 30 seconds. The machine is always kept warm and in readiness. It is particularly useful for getting the motor driven auxiliaries of the main units in operation when starting the plant so that the main units may be started condensing.

There are 3 turbo pumps at the tide water pump station. They are about an eighth of a mile distant from the central plant and can be started or stopped by remote control switch and all those pumps can be connected into the 18 inch circulating water main to the condensers if needed.

Power is supplied to the steel mills of the Nova Scotia Steel Company at 2100 volts and to the Nova Scotia Steel Shipyards at 600 volts (A.C.) and 250 volts (D.C.) also to the wheel foundry at 600 volts (A.C.) and 250 volts (D.C.) the balance being used in the car plant. The power house lighting system is so arranged that should anything occur at night to interrupt the main lighting system, one of the separate exciters, being steam driven, can be pressed into service for lighting the power house and boiler room and also supply power for the overhead crane.

Air Compressors

No. 1 compressor—Can. Rand compound non-condenser steam Corliss driven, capacity 3000 cubic feet per minute, at 90 R.P.M.

Steam cylinders 17"/34"x36".

Air cylinders 34"/20"x36".

No. 2 compressor—Can. Rand "Simple" non-condensor steam tandem compound air straight line type. Capacity 1000 cubic feet per minute. Equipped with Myer cut off size.

Steam cylinders 20"x12" stroke.

Air cylinders 20"/12"x12" stroke.

The steam is supplied to this engine through a reducing valve at a pressure of 125 lbs per square inch.

Hydraulic pump. Non-condenser Laidlaw, Dun & Gordon (Cincinnati, Ohio) now known as the International Steam Pump Company. This pump has a capacity of 400 gallons per minute against a 3000 feet head. The steam pressure is 175 lbs. at the throttle. This is a three-crank high duty engine-driven hyd. pump, having steam cylinders 19/30/30 by 24 inch stroke, and water pistons (outside packed) size 5 inch, the common stroke being 24 inch.

The engine is a Corliss, having single eccentrics with releasing gear on the H.P. cyl. and an adjustable knockoff cam. There is also a flyball governor which arrangement rather puzzles the beholder at first. However the flyball governor is a necessary provision when the nature of the work is understood.

In order to maintain a constant pressure on the hydraulic system, there is an accumulator with a 16 inch piston or ram floating on the line, weighted to 150 tons. At 1500 lbs. per square inch the piston begins to raise the weight, since the area of the 16 inch piston (201 square inches) times 1500 = 300,000 lbs. = 150 tons. When the piston reaches the limit of its travel (18 feet) it leaves a storage space which is equivalent to the piston displacement, equal to

$$\frac{201 \times 18 \times 12}{1728} = 25.12 \text{ cubic feet.}$$

When the accumulator weight reaches nearly the top of its travel it engages an arm to which is connected a cable passing over pulleys to the chrometer valve on the steam main to the high pressure cylinder. Any further travel must, therefore, close the pump down. When the accumulator ram falls again, due to withdrawal of water by the hydraulic presses, the chrometer valve is again opened and the pump starts up.

Oil and Water Separator

All the oil used on the reciprocating engines is collected in a home-made separator in the engine room basement. The operation of the separator is automatic and for a home made affair is worthy of description. The whole thing is made of galvanized iron and a few bits of pipe. The tank is divided into two compartments as shown in sketch. The oil, after being used in the engines, flows by gravity through a pipe and is delivered in compartment (A). The oil and water separating at (C) the oil rises to the top and the water is displaced through (D). At the same time there will be a displacement of oil at (E) into compartment (B), from where it is pumped by a hand pump to a 30 gallon Cross oil filter. The quality of the separated oil depends upon the difference in height of points (D) and (E). The best adjustment can be found by trial. It is easy to adjust if elbow (E)

(Continued on page 36)

Efficient Operation of Oil Burning Plants

A Discussion of the Plant—Characteristic Diagram, with Particulars Regarding its Use in the Establishment of a Standard of Performance and in Increasing Plant Efficiency

By C. H. Delaney*

DURING the past ten years there has been a remarkable increase in the efficiency of steam plants, both oil-burning and coal-burning. Ten years ago there were many plants operating reciprocating engines, in which the maximum economy obtained was not over 150 kw-hr. per bbl. of oil.

With the high-pressure steam-turbine plants of the present day a record of 330 kw-hr. per bbl. has been made. This increase in efficiency has been brought about by introducing more efficient machinery and increasing the range of steam pressure in the prime mover. The introduction of the steam turbine to replace the reciprocating engine effected a remarkable saving in the quantity of fuel required. Moreover the steam turbine caused a saving in operation due to the fact that its operation does not depend on the personal element in the plant.

In the old reciprocating engines there were many adjustments to be made by the engineer in charge, and the economy obtained depended very largely on the skill of the operating engineer and the care with which he made the various adjustments. With the steam turbine, however, there is nothing that the operator can do to improve the efficiency after the machine is once installed and placed in good operating condition. While this is true as regards the prime mover, it is not true in regard to many other features of the power plant. In the boiler room particularly there are many points where the operating engineer can effect a saving if he carefully studies the situation and pays attention to the small details of operation.

In condensers and vacuum pumps also a great saving can be made if proper attention is paid to maintaining a high vacuum. There is still, therefore, a large field for the operating engineer in improving the economical operation of the plant, and the question of operating efficiency is consequently one worthy of very careful study.

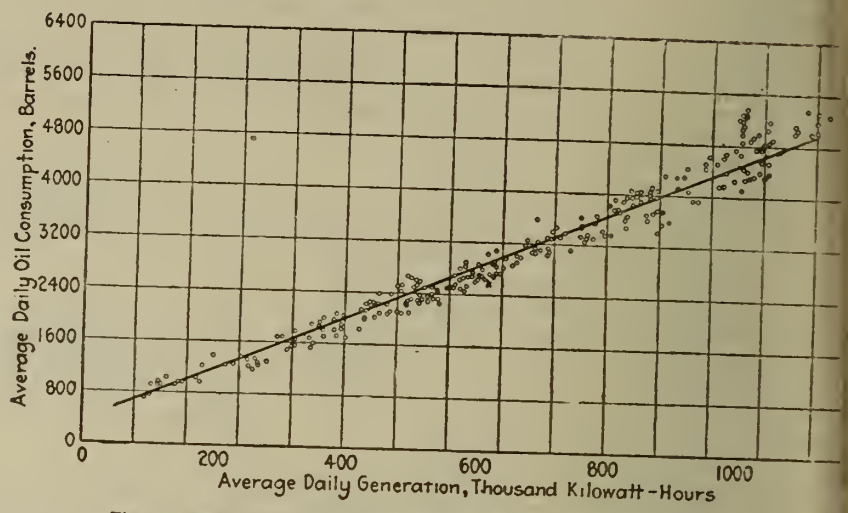


Fig. 1—Plant characteristic diagram for a San Francisco station.

Many tests have been published showing very high efficiency of boilers where fired with fuel oil, efficiencies as high as 80 and 82 per cent being not uncommon in test reports. It is very rare, however, that any such efficiencies are obtained in the regular operation of power plants. In order to maintain high efficiency in regular operation of a plant, the first requisite is some means of comparing one day's operation with another. In oil-burning electric power plants it is customary to report the economical operation of the plant in terms of kilowatt-hours generated per barrel of oil. This is an excellent method of comparing one day's operation with another provided there is steady load on the plant and conditions remain the same from day to day. With a variable load, however, such as occurs in an ordinary central-station plant, it is always found that the economy is much better at periods of light load. Thus it is possible with a fairly heavy load on the plant to secure from 220 to 230 kw-hr. per bbl. of oil without difficulty, whereas with the same plant operating at a light load it may be difficult to secure more than 150 kw-hr. per bbl. of oil.

When the good results are obtained with the heavy load, the operating men pat themselves on the back and consider that they are doing fine, because results are better than the average. On the days of light load when the results are poor, they do not worry but say, "What's the use, you can't expect good results with such a light load." Thus in neither case is there any incentive to improve the economical operation of the station. Another reason for more or less lax methods, so far as efficiency is concerned, is the fact that efficiency must always be secondary to continuity of service. The men at the plant know that any interruption to service will be a matter of close investigation on the part of the management, and they devote all their energies to maintaining the plant in operation and keeping the lights burning. For instance, if a fireman in endeavoring to carefully adj

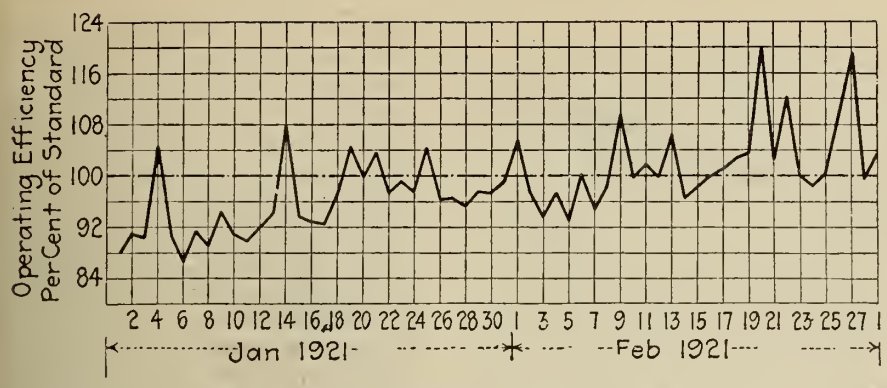

Fig. 3—Diagram of operating efficiency over two months period.

the air supply in boilers neglects to keep up the steam pressure, with the result that the turbine slows down and some of the load has to be dumped, he is sure to be called on for an explanation. If on the other hand he keeps up the steam pressure, but neglects to regulate the air in the proper proportion, there usually will be no complaint; and the boilers may be allowed to operate in this inefficient manner for a considerable length of time. The author is far from disputing the fact that continuity of service is a matter of prime importance, but he does wish to point out that efficiency is a close second. The problem before us, therefore, is to so interest the men who are operating the plants in the matter of efficiency that they will not neglect the various operating details that must have attention in order to secure good results.

In order to improve these conditions and to interest the men in the problem of efficiency, it is essential to devise some means of comparing the performance of a plant from day to day. For this purpose, the diagram here called the "plant characteristic diagram" has been plotted.

The Plant Characteristic Diagram for Comparing Performances from Day to Day

Fig. 1 shows such a diagram from one of the San Francisco stations. It consists merely in the plotting of the oil consumption against the kilowatt-hours generated. Each of the points in this diagram represents one full day's operation, and while the points as shown are more or less scattered, it is apparent that they form a well-defined line. It is thus possible to draw a straight line through the midst of these points in such a way that it will represent the average location of all the points in the diagram. There is nothing new in the use of a straight-line diagram, such as is presented. The line is similar to the Willans line for steam engines, where for throttling engines the total steam consumption plotted against the horsepower output is always found to be a straight line. A similar line for steam turbines is either straight, or very nearly so, depending on the design of the turbine. The use of the Willans line in the design of steam power plants was very ably described by R. J. S. Pigott in a paper read before the A. S. M. E. in 1916. [1]. The use of the plant characteristic diagram in improving the efficiency of steam plants has been described very fully by Robert H Parsons[2] of London; and in fact in describing this system as applying to oil-burning plants, the author is simply amplifying Mr. Parsons' paper on the subject.

Use of Diagram as a Standard for Guidance of Men in Operation of Plant

The diagonal line, having once been drawn through the points as described, may be used as a standard for the guidance of the men in future operation of the plant. Thus each day the kilowatt-hours generated and the oil burned the day before may be plotted on this diagram. If the point so plotted is found to fall below the diagonal line, it is evident that the results obtained are better than the standard. If the point falls above the line, too much oil has been used, and there is something wrong requiring a special investigation; and since the diagram takes in all loads from zero up to the full load on the plant, it is evident that it allows for the poor economy obtained at light loads. It is thus possible for the operating men to know immediately whether they are keeping up to the required standards of efficiency or running behind. They are therefore able to investigate causes of low efficiency immediately while all matters entering into the plant operation are fresh in their minds.

In adopting the standard it would be possible, instead of drawing a line through the average of the points, to draw a line through the best points, thus establishing a standard that would represent the best results obtainable from the plant. Again it would be possible to establish a standard by drawing a theoretical line below all the points, this line to be based on the steam consumption of the turbines and auxiliaries, as determined by tests, a boiler efficiency of, say, 80 per cent and the best possible vacuum. In other words, a line representing ideal conditions.

In adopting the average line as the standard it is felt that the men will have greater confidence in the method than if a theoretical line has been adopted. The average line is really a standard that has been established by men themselves. It is not an arbitrary ideal impossible to attain, but represents the average already attained. It should be as easy to improve on the results represented by the line as to fall below them.

If the men are successful in improving on the standard each day, it is obvious that the average for a given year will represent better efficiency than the average for the previous year. With all of the points falling below the line of the diagram, another line drawn through the average of these new points would also fall below the original line.

A diagram with the same diagonal line as determined by Fig. 1, but with the points omitted, may be used at the stations each day to plot the results of the day before.

Figure 2 shows a similar diagram, but with the scale altered so as to show the kilowatt-hours generated and the oil burned during a period of 8 hours instead of 24 hours. This diagram may be used by the different shifts in the station so that each shift can check up its own performance and compare it with the performance of the other shifts. A large diagram of this form is posted on the wall of the fire room, and different colored pins to represent the different shifts are inserted each day so that the diagram shows at all times which shift is running above the line and which shift is running below it. This system has a far-reaching effect in awakening interest in the men and leads to rivalry and competition so that they are extremely anxious to improve the efficiency, and the laxity which previously existed in regard to efficiency is disappearing. As the diagram allows for variations in load, it is possible to compare the day shift when the load is heavy with the early morning shift when there is very little load on the plant, thus making a fair comparison which was never possible with the old method of merely figuring the kilowatt-hours per barrel of oil.

There is one objection to the diagram —it does not indicate the order in which the records are plotted, and therefore does not show whether the results are improving as time goes on. In order to overcome this objection, and also to enable the operation of different plants to be compared with each other, the term "operating efficiency" has been introduced. Operating efficiency as used in this connection means the percentage of standard attained for the day's run. "Operating efficiency" is entirely distinct from "boiler efficiency" or "thermal efficiency" or "Rankine-cycle efficiency." All of these enter into the operation of the plant in determining the standard. Operating efficiency is merely a comparison of the results actually obtained with the standard.

The method of determining operating efficiency can best be shown by an example: During one eight-hour shift there were generated 313,000 kw-hr.

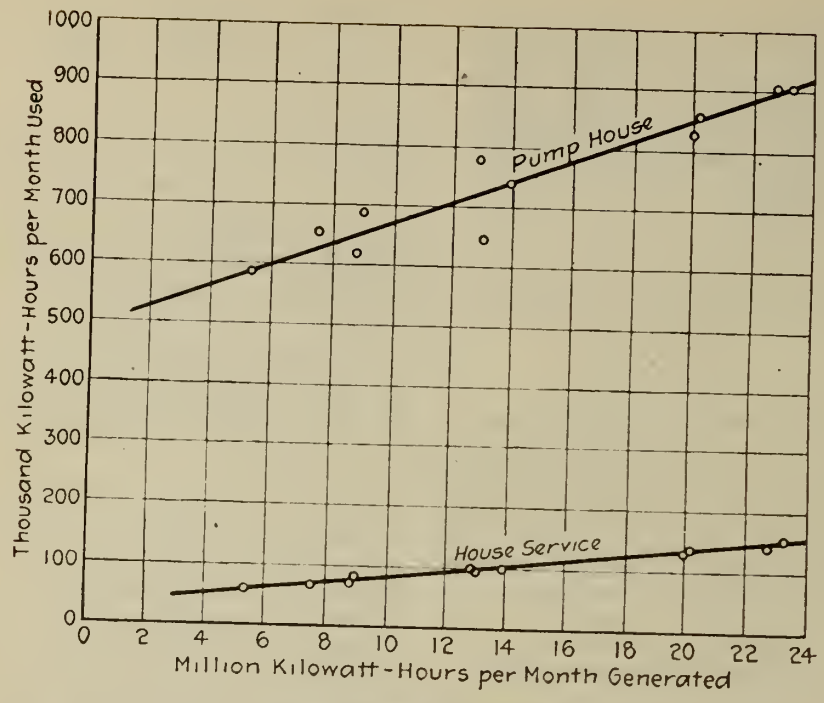

Fig. 4—Power used by electric auxiliaries, plotted against total generation.

and 1440 bbl. of oil were burned, representing an economy of 217 kw-hr. with standard efficiency, there would be burned only 1400 bbl. of oil, which would be equivalent to 224 kw-hr. per bbl., as against the actual result obtained of 217 kw-hr. per bbl. The operating efficiency is therefore 217 divided by 224 or 97 per cent. During another eight-hour shift, where there were only 25,000 kw-hr. generated, the oil burned was 200 bbl., equivalent to 125 kw-hr. per bbl. From the diagram it is found that for 25,000 kw-hr. with standard efficiency the oil burned would be 220 bbl., equivalent to 114 kw-hr. per bbl. The operating efficiency is therefore 125 divided by 114 or 110 per cent. It is thus seen that although in the second case there were only 125 kw-hr. per bbl. obtained, as against 217 in the first, operating efficiency was actually higher in the second case than in the first.

It is evident from the foregoing that if an operating efficiency of 100 per cent is obtained, it means that the economy of the plant is the same as the average of last year, since last year's records were used to establish the standard. If more than 100 per cent operating efficiency is obtained, the results are better than last year, and if less than 100 per cent is obtained, they are worse. It is obvious that this method of determining operating efficiency makes allowance for inefficient machinery, and it is just as easy to obtain 100 per cent operating efficiency in a plant having old-fashioned turbines of poor design as in a plant having the most up-to-date machines, for the standard is based on the actual records of the plant in question.

Fig. 3 shows the operating efficiency of one of the plants plotted for each day during the months of January and February. In this diagram the horizontal line at 100 per cent represents the standard efficiency and the zigzag line the actual operating efficiency obtained each day. The records show a gradual improvement in the operating efficiency during the period, which is a direct result of the attention to small details brought about by this method of checking up efficiency.

In addition to the use of the diagram for setting standards and creating interest among the men, a system of weekly and monthly reports and bulletins has been adopted. The weekly report, which is made out by the efficiency man at each station, gives the operating efficiency for each day and the average for the week, and in addition a brief statement of some of the more important instrument readings such as flue-gas analysis, vacuum, feedwater temperature, and steam consumption of turbines at different loads. The monthly report which is made out at the office and sent to each station includes a diagram of operating efficiency similar to Fig. 3 for all stations plotted on one sheet, together with a brief statement of comparative results obtained and suggestions for improved methods. A liberal use is made in the stations of flowmeters and other instruments that serve as a guide to the firemen in the proper regulation of their fires.

Since the diagonal line in the plant characteristic diagram is usually a straight line, it can of course be represented by a simple equation, namely:

$$y=a+bx$$

where y is the consumption in a given en period in barrels or pounds, x the kilowatt-hours generated in the same period, and a and b are constants.

Evidently the constant a is equal to y when x=O, or in other words a represents the quantity of oil burned for zero load; that is, the amount required to keep up steam on the boilers, keep the turbine running up to speed, operate the vacuum pumps and other auxiliaries, and keep the entire plant in readiness to take on load at a moment's notice. Obviously a will be larger if two turbines with their auxiliaries are kept in operation than only one, so that its value depends on the amount of load the plant is expected to take on. Where a plant is operated as a stand-by to a hydro-electric system and is kept in readiness to instantly pick up its full load in case of trouble, a will have a higher value than where it is possible to gradually shut down the turbines one after the other as the load falls. The constant b evidently represents the additional amount of oil burned in proportion to the load carried on the plant. It determines the slope of the line in the diagram, and is large for uneconomical turbines or engines and small for the most efficient types. The equation of the line in Fig. 2 in terms of barrels of oil and kilowatt-hours for an eight hour shift is—

$$y=120+0.0041\ x$$

Other Uses of The Plant Characteristic Diagram

The characteristic diagram may be used for many other purposes besides the overall efficiency of the plant. By plotting the steam generated against the oil burned in one diagram, and the steam consumption against the kilowatt-hours generated in another, it is possible to study the boiler-room and engine-room operations separately, and thus quickly locate the cause of low efficiency. By setting separate standards for the boiler-room and engine room crews, responsibility can be more definitely fixed and the advantages of the system of operation greatly enhanced.

Since boiler efficiency usually decreases quite rapidly as the capacity increases above the boiler's rating, a single boiler will naturally have a curved characteristic. In a plant containing a large number of boilers, however, the boiler-room characteristic will be approximately straight until the load exceeds the economical capacity of all the boilers in the plant, after which it will begin to curve upward. A curved line, based on previous performance, is just as satisfactory as a straight line for setting standards and calculating operating efficiency in the manner described. Fig. 4 shows the power used by electric auxiliaries in a station plotted against the total generation, and is of interest in showing that the points do form well-defined straight lines, and that the same methods may be used for standardizing these items as for fuel consumption and steam consumption.

To sum up, the essentials for securing

the best efficiency in power-plant operation are;

1 A fair standard by which the daily performance can be measured and compared with previous results, at the same time giving the operating men a definite goal to work to.

2 Means of comparing results obtained by different shifts of one plant or the crews of different plants, and the posting of this comparison so that the men can see the results of their efforts.

3 A system of reports that keeps up the interest of the men, combined with suggestions and advice that show where losses occur and how they may be avoided.

If the operating men are kept interested, see the results of their work, and have a definite standard to reach, they will do their best. As interest flags some sort of bonus or prize for the crew showing the best operating efficiency will stimulate them to greater effort, and by guiding this effort by means of thoughtful analysis of the technical features of the power plant, maximum efficiency may be obtained.

TORONTO SECURES NOVA SCOTIA COAL

Expect to Ship Coal Direct From Mines Believes This Will Overcome Shortage Troubles—Low Cost Said To Be Obtainable

Soft coal from the Sydney mines in Nova Scotia arrived in Toronto recently. According to Mr. Malone, western sales manager for the Century Coal Co., it is the intention of his company to deliver this coal direct by steamer to Toronto. Other steamers are at present en route to Toronto with further supplies.

Mr. Malone states that his company has succeeded in landing the Nova Scotia coal in Toronto at an economical cost, thus enabling them to meet the competition prices of coal from the United States. In this connection, Mr. Malone points out that the Turret steamers which are used have capacity for 4,000 tons. Owing to the limited depth of the Cornwall Canal they are obliged to lighter 2,000 tons at the bunkers in Montreal, the remainder of the cargo being brought direct to Toronto. After lightening her cargo in Toronto the steamer proceeds to Port Colbourne and loads grain for Montreal and other eastern points, thus giving the steamer the benefit of cargoes in both directions, the loading in each case, likewise, being accomplished in much faster time than ordinarily required to load freight consignments. This in itself, Mr. Malone states, makes it impossible for the company to compete with coal from the mines across the border. Under present conditions Toronto will be the western point of destination for the eastern coal until such time as the business develops and conditions at other points on the Upper Lakes warrant the transportation of this coal in that direction.

Assurance has been given by several large manufacturers in Montreal and members of the Montreal Harbor Commission that the Nova Scotia coal is equal in quality to that which is brought from Pennsylvania.

Mr. Malone believes that this will prove a practical solution in overcoming shortage conditions at certain seasons of the year, so far as soft coal for manufacturing purposes is concerned.

CANADIAN-BUILT PAPER MACHINES

In the Sept. 22nd issue we mentioned the installation of two 166 inch news machines by the Laurentide Co., Limited, Grand 'Mere, Que. These machines were built in Canada by the Dominion Engineering Works, Limited, at Lachine, Que., and represent a record in Canadian Machine Building. They were ordered in October, 1919. One machine was installed January 5, 1921, and the other February 2?. 1921. While these machines were being built, the makers rebuilt parts of these other machines and turned out a new 90 inch, four cylinder board machine, and 1418 inch Harper Fourdrinier machine, all of which represent a remarkably good rate of production of special machinery in a new plant. Speeds of 1,000 lineal feet per minutes of paper produced have been reached on kraft paper, but these 166 inch machines are now producing newsprint daily at the rate of 1000 to 1030 feet per minute, and the combined product of the two machines averages 160 tons daily.

Machines for operation at such high speeds must necessarily be equipped with all the latest devices for handling the sheet through the machine and for insuring freedom from breakages and getting practically continuous production. When one considers that under the above conditions, the speed of a 30" diameter couch roll is 127 r.p.m., it is evident that the limit of human skill in handling paper through the machine by hand has been left far distant.

The Toronto Harbor Commission have given an option on ten acres of property at $60,000 an acre. The type of industry which proposes locating in Toronto is so far a secret although the very location chosen leads one to believe the new plant will be engaged in the metal working field.

Toronto, Ont.—About half the usual staff of the Massey-Harris Co. went back to work a few days ago to fill a foreign order. Nothing definite is stated as to future prospects.

TOO BUSY TO STOP FOR ANYONE.

Exchanging Experiences

A CORRESPONDENT who writes in this issue calls attention to the fact that very few stationary engineers in Canada seem to send their experiences to their technical journal for the benefit of their fellows, while the engineers in the United States seem to be very prolific in this direction. There is no doubt that our correspondent is right, though of course, some of the difference in the amount of correspondence is to be found in the difference in numbers of the engineers in the two countries. The chief reason, is, we believe, the diffidence that so many men seem to have in giving voice to their thoughts in public. This is notable in every gathering of men, whether they are members of any particular profession or merely a gathering of citizens met to discuss some point of general interest. There will be one or two who will more or less monopolise the speaking, and these outstanding speakers will not always represent the best brains of the gathering. However, they are not troubled by bashfulness, but on the contrary have a remarkable degree of self-confidence, which carries them along, while better men sit quietly and listen.

In a gathering of men, of one trade or profession, met together for the purposes of mutual benefit, there are often those who have points that they would like cleared up, or some things that they are absolutely ignorant upon, and they leave the points still in doubt, and remain ignorant of the things they want to know, because they fear that by asking a question they will cause some other member to look down upon them. This state of mind should not be allowed to exist. A man with a question to ask should ask it, without any fear of ridicule, because it is very often the case that there are others in the gathering with exactly the same doubts, holding back for the same foolish reason. They may rest assured that the ones who laugh at them are not the ones who can answer their question, and clear up their doubts. Those that possess the necessary knowledge are those who have gone to the trouble to get acquainted with these points, and have not been afraid to ask questions whenever they had them to ask.

It is the same way in giving others the benefit of experience through the medium of the printed word. The fear of not being able to express one's ideas in proper form, or the feeling that the experience is perhaps not worth while recording, often results in something of value to the profession in general being hidden. It is a pretty safe rule to go by, that any happening in the course of daily work that appears to be of unusual interest to the man it occurs to, will be of interest to others, and not only of interest, but of help. Those great discoverers of other days, who first advanced the theory that heat was not a substance, but rather a form of energy, had lots of opposition to face but they had the courage of their convictions, and the present state of steam engineering is due to that courage. The sum total of engineering knowledge in the world today is only the sum of other men's experience set down and distributed broadcast so that all who wished might benefit. There are men whose only contact with others of their calling is through the medium of their technical journal, and to whom the reading of some plant trouble met and overcome would be invaluable. Is it not worth while to help a brother along the road, even if it involves a little trouble? The knowledge of little things that help in the daily task is just as welcome as the learning of broad principles, and it is only from the man engaged in actual practice that these little tips can come.

Exporting Hydro Power

THERE has been some suggestion that the Hydro Electric Power Commission should export some of its surplus power, which will be available on the completion of the Chippewa development, or on its partial development. It is said that the suggestion has been so far developed that a price of $35 per horse power has been offered by the Commission. We do not know if this is actually the case, but if it is it seems a strange thing that a publicly owned utility in Canada should go to an expense running into hundreds of millions of dollars in order to give cheap power to an American city. The only excuse there is for a publicly owned utility is that the people of the country should benefit from it by getting service at cost. Whether the people have been getting service at cost or under or over cost from the Hydro is not a point that we wish to bring up here, but that an American city should get power from Ontario at cheap rates or any rates at all in order to run industries that are competing with Canadian industries does not seem good business. If the fact is that the development is far in excess of the needs of the Province for a long time to come, it is unfortunate, but part of the price to be paid for an unreasoning belief in the wonders of public ownership. We expect that if any private company in Ontario was to develop part of the waters of the Province and then export them there would be a mighty howl from the friends of the people who are wedded to the public ownership of everything in sight.

TORONTO LODGE C. A. S. E.

Toronto Lodge No. 1 staged the opening celebrations of their new lodge room at Cumberland Hall on October 18th, when there were about one hundred members and friends present. The evening was devoted to entertainment and amusement, and a varied and attractive program was presented. There were twenty numbers on the program which is reproduced here.

One of the most amusing events of the evening was a dialogue, purporting to be taking place between an applicant for a certificate and a member of the board of examiners of the Stationary Engineers. The part of the applicant was taken by Brother Leach, while the examiner was Bro. Turner. The dialogue is good enough to reproduce, and we here do so.

An address was given by the chairman of the examining board, and in the absence of Mr. D. Crockett, the gap was filled by Dad Wickens, who gave the audience a general resume of the history and prospects of the C.A.S.E., about which Dad is well qualified to speak. Mr. Fenner, who was down for a song, was also unfortunately unable to attend, and his place was taken by Mr. Grant Cole of the Cole Trap Co., and Mr. N. Kingsland of Power House, who gave a short address.

Toronto lodge have certainly got away to a fine start in their new home, and we sincerely hope that success will crown their efforts in the future.

PROGRAM

Cumberland Hall, Oct. 18, 1921.

(1) Music—Interlude, "Hot time in the Old Town Tonight."

(2) Welcome to visitors by President of C.A.S.E. (8 p.m.)

(3) Song, "The Maple Leaf," by the whole audience.

(4) Introduction of L. J. Ellis.

(5) Reply by L. J. Ellis to "Visiting Brethren" (8.10).

(6) Song and music. (8.15).

(7) Introduction of J. M. Brown by President (8.30).

(8) Song, "For He's a Jolly Good Fellow" (8.35).

(9) Address by J. M. Brown "The Graded Licenses" (8.45).

(10) Dialogue "An Examining Board" (9.00).

(11) Song and music (9.15).

(12) Introduction of D. Crocket.

(13) Song, "See Him Smiling," etc.

(14) Address by D. Crocket, "The C.A.S.E. Advantages," (9.30).

(15) Song by T. H Fenner (10.00).

(16) Invitation to eats by A. M. Wickens (10.15).

(17) Refreshments.

(18) Vote of thanks to ladies (11.00).

(19) Group photo (11.15).

(20) Dispersal and song, "God Save the King" (11.30).

Entertainment Committee

A. M. Wickens, Chairman; A. E. Wagg, C. B. Turner, Geo. J. Soucy, Ed. Golightly, George Bones, T. Turner, R. C. Leach.

THE EXAMINING OF PROSPECTIVE ENGINEERS.

Personata—Applicant, Bro. Leach; Examiner, Bro. Turner; Clerk, Bro. ———. Scene, office of examining board.

Enter the Applicant—Clerk with roll in hand (to act as prompter). Examiner whittling in corner.

Clerk—How'd you come to blow in here? Applicant—Well, the door was open so I just perambulated along, see?

Clerk—Who are you? Applicant—Oh, just a guy looking for Sir Tificat. Is he here?

Clerk—What do you want? Applicant—The examining board. (Clerk hands him board 1"x12"x4'0").

Applicant—What's that for? Clerk—Board for you to be examined on.

Applicant—Are you the guy that does the examining? Clerk—No, he's busy.

Clerk—Do you want to be examined? Applicant—Yeh, I suppose so, especially if he's too busy.

Clerk (To Examiner, stamps)—There's an awful smart fellow over there wants to be examined, and say he's so sharp that if he ever fell on himself he'd be cut in two in a jiffy.

Applicant—Hello, old top, are you the executioner around this joint? Examiner—Evidently you need an examination; are you fresh from the soil.

Applicant—Say, quit your kidding and let me see how little you fellows know up here.

Examiner—Sit astride the board if you want to be examined, and repeat after me the formula C.A.S.E. or anything else you like best.

(Examiner takes large magnifying glass and examines head of applicant).

Applicant—What's the big idea—do you think it's vacant? Examiner—No, I wasn't thinking at all. Just looking to see if there was any evidence of ashes, coal dust or grease.

Applicant—Well, just look at these hands if you want to find out how much I know about boilers and engines.

Examiner—That isn't the point. We want to find out how much you don't know.

Applicant—Say, old top, if you know anything I don't know, just shoot it out.

Examiner—What questions do you think I should ask you? Applicant—None at all—tell me something instead.

Examiner—What do you want to know? Applicant—How to get Sir Tificat without examination.

Examiner—Go to an employment bureau and tell them you want a job without pay.

Applicant—Say, what's the idea of this examining board anyway—just to get some easy money from us fellers that has to work around steam in winter time, eh?

Examiner—Did you say you liked to work around steam? Applicant—No, I said we had to work around steam in the winter time, and in the summer we like to work around an ice house.

Examiner—Did you find anything in the last ice house you worked around? Applicant—Shhh, B.O.T.A.

Examiner—Have you let off all your steam? If so be still a minute and I——

Applicant—Say, Mr. Examiner, I'd sooner have you talk about steam than stills and worms.

Examiner—Well, what do you know about steam—what is it? Applicant—I know all about it—it's water gone crazy with the heat, and believe me it was some hot last summer.

Examiner—What do you mean by heat and hot? Applicant—Well the heat was so hot that some people said last summer that the weather was almost as hot as "Hell bent for Election."

Examiner—I see you learned something about religion as well as heat and steam. What do you mean by Hell? Applicant—Oh, that's a convenient place to send our enemies in the winter time.

Examiner—What do you know about firing? Applicant—Know, why, all about it—I just got fired.

(Clerk interrupts and suggests asking applicant)—Does he expect to become an expert?

Applicant—Yeh, I'll go buy a white collar and a white shoit and then I'll be an expoit.

Examiner—What kind of an expert will you be? Applicant—Expert! Boiler, Engine, Heater, Condenser, Filter, Economizer, Damp-her regulating, Flue-cleaner, Ash and Coal Conveyer, etc. (Clerk interrupts):—Say, that'll do old sport.

Examiner—What did you have in your plant? Applicant—An engine, boiler. Examiner (interrupts)—But why did you boil the engine? Applicant—To make it tender service for de boss.

Examiner—What do you know about an engine? Applicant—Everything about it, but I never was inquisitive about its internal parts, because familiarity might lead to repair work.

Examiner—What grade license do you want us to grant you? Applicant—The kind that I won't have to pay much for, and when I get it I won't have to work no more.

Examiner—Is there anything else you'd like? Applicant—Yeh, I'd like to tell you fellows what I tell my friends about you, but I can't remember it all.

Examiner—Well, tell us what you do remember? Applicant—Oh, nothing, it ain't so anyway.

Examiner—What? Applicant—Well, I said before I came here that I knew more in a minute than you fellers'd ever know—and now I don't know nothing, but say, I'm going to join the C.A.S.E. and see if they know any more than I do.

Examiner—Well, come back and see us again after they knock off some of the rough corners. Clerk—Just fill in this application card and I'll tell them about your CASE.

Applicant—You can't tell, I may be the Past President o the Grand Lodge of the C.A.S.E. yet.

Examiner—Yes, and I may revise your constitution an guard your inner courts yet.

(Curtain.)

Flourish and exeunt.

The Increased Use of Fuel Oil

FUEL oil, for use in oil burning equipped plants, has increased remarkably during the past year. J. J. Tyrell, in "Textile World," gives some interesting figures relative to this subject. Speaking of the oil burning boilers used by textile mills in New England and New Jersey, he says that approximately 50 textile plants with over 400 boilers were converted from coal to fuel oil. The oil consumption exceeds 4,500,000 barrels, displacing about 1,125,000 tons of coal per year.

The outstanding fuel oil installation in point of size, according to Mr. Tyrell, is that of the American Printing Company, at Fall River. The main storage consists of a concrete tank with a capacity of 640,000 gallons. This tank is about 30 feet from the boilers and oil is fed to the boilers by means of pumps. The storage tanks are provided with heating coils to hold the temperature of the oil to approximately 100°F. These heaters utilize the exhaust steam from the oil pumps.

In selecting apparatus to handle the oil some attentio must be given to its quality; that is to say, whether it i light or heavy. It is my opinion, says Mr. Tyrell, that al though the first cost of the apparatus to handle the heavie oil is greater, it is economical from an all-around view point to install the apparatus to handle the heavier oil. Suc installations will allow the engineer to take advantage of th market without regard to the nature of the oil.

Developments during the past year were chiefly concerne with the design and development of furnaces for high overloads. It is, of course, generally known that it is not economical to operate boilers on overload for any length of time. Yet, it is necessary to have them operate over shor intervals to take care of big loads. In concluding, he says that the men who burn the oil ought to be given apparatus to guide them to the best way to get efficient results, and to be certain that they know the purpose of such apparatus when installed.

THE POWER PLANT OF THE EASTERN CAR COMPANY

(Continued from page 29)

is swung on its thread so as to elevate or lower the point of discharge.

The principle upon which the separator works can be demonstrated by taking a U-Tube and filling half full of water, put some engine oil in one side. The oil will displace the water until the leg containing oil is full. It will now be noticed that while the oil leg is full the water leg is not full, but the water level is lower than that of the oil. This is due to the difference in specific gravity.

The use of the collector separator just described permits the oil from the sight feeds to be fed liberally to the engine bearings, since it is again recovered. There is no attempt made to save the oil used on the auxiliaries, and this amount must be added to the Cross filter tank each day, thus keeping the viscosity of the oil from getting too low. It is not our intention to recommend this apparatus as being better or even as good as some of the filter separators on the market, but it is better than nothing and costs very little. However, the apparatus described here seems to be very efficient and is a great improvement on the old paint can or oil cask frequently encountered.

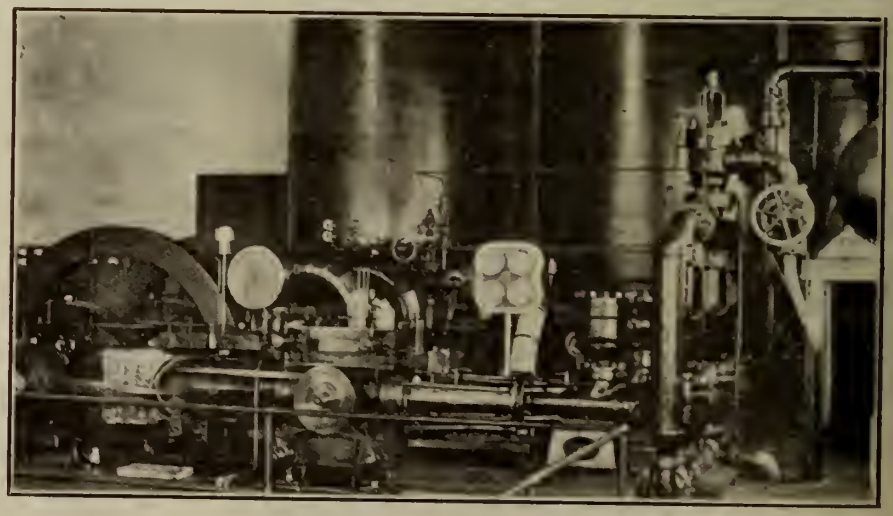
WOODSTOCK C. A. S. E.

C.A.S.E. Lodge No. 37, Woodstock, held a meeting recently at which a lecture was delivered on Boiler Settings and Combustion Space. Mr. C. Andrews was present and gave some interesting facts on this subject. Bro. Arnup was in the chair, and it is satisfactory to note that owing to the interest shown by Bro. Arnup and Bro. Watts, a sum of $75 has been collected towards the purchase of a lantern for the use of the lodge. It is hoped that at the next meeting the lantern will be ready for use, and interesting evenings will be forthcoming. Woodstock Lodge has now twelve new members on the books, and some more are expected to join in the next few weeks. The meeting was brought to a close by the passing of a hearty vote of thanks to Mr. C. Andrews, for his interesting lecture.

The Toronto office of the Independent Pneumatic Tool Company has been removed from 32 Front Street West to No 163 Dufferin Street. The new location will give this company larger space and increased stock facilities. The Toronto Office will remain in charge of Mr. Willima McRae.

COLOR VERSUS HARDNESS

Quite often a workman spends considerable time in carefully drawing the temper of a piece of carbon steel, only to find to his dismay that it is soft, while yet the color is real light brown! It upsets his ideas of steel and hardening. Really, the trouble is that the piece was not hard when taken from the water. Either it was not hot enough to harden when dipped, or else it was removed from the bath too soon and drew itself before the black was polished off. Test the piece as soon as taken out of the hardening bath—it is quite apt to prove soft. Remember that the **same** colors can be produced on a piece of mild steel but they do not indicate a state of hardness.



Hydraulic pump and accumulators.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

CONSUMPTION OF STEAM PUMP

Question.—What is the consumption of a feed pump size 14 inches diameter x 24 inches stroke, making 40 strokes per minute, with a steam pressure of 180 lbs. per square inch. The pump in question is a Weir?

Answer. — The consumption of a steam pump will depend on whether or not the steam is carried the whole length of the stroke or otherwise. With the make of pump in question, it is usual when working properly to cut the steam off at about seven eights of the stroke, finishing the stroke expansively. The consumption in the two cases, first carrying the steam the whole stroke, secondly cutting off at .875 of stroke. The volume of the cylinder is 14 x 14 x .7854 x 24 cubic inches, and this divided by 1728 will give cubic feet per stroke. The volume per stroke or cylinder volume multiplied by the number of strokes per minute will give the cubic feet per stroke. The volume per stroke or cylinder volume multiplied by the number of strokes per minute will give the cubic feet of steam per minute. Multiplying this by the weight of a cubic foot of steam at the pressure given will give the weight of steam per minute, and multiplied by 60 the consumption per hour.

The working will be

$$\frac{14\text{x}14\text{x}.7854\text{x}24\text{x}40\text{x}60\text{x}.4241}{1728} = 211.56 \text{ lbs. per hr.}$$

If the pump is cutting off at seven eights the consumption will be

$$211.56 \text{ x } .875 = 185.11$$

The weight of a cubic foot of steam at 180 lbs. gauge is .4241 lbs.

LIFT OF SAFETY VALVE

Question.—It was stated in the September issue of Power House that a spring loaded safety valve will raise from its seat a distance in proportion to the pressure of steam over and above the pressure it is set for. That is a 6 inch. spring would lift one quarter of an inch at 104 lbs. Will it raise ½ inch at 108 lbs. and 1 inch at 116 lbs. Is a ball and a lever valve subject to the same rule and if not how does it differ?

Answer.—Our correspondent has evidently misunderstood the statement in the issue he speaks of. What was stated was that the fact of the valve lifting produced a greater compression of the spring in direct proportion to the height the valve lifts, and for this reason a lip was formed on the valve to give a greater area to counteract this extra compression of the spring. The valve lifts an amount sufficient to give an opening about equal to the area of the valve. A lever safety valve is not subject to the same rule, as there is no extra leverage due to the valve lifting, such as the extra compression on the spring of a spring loaded safety valve. In connection with the amount of lift, supposing we have a valve of 3 inches diameter, its area would be 7.06 inches. Now in order to obtain the same area the valve must lift an amount equal to the circumference divided into the area, or 3 x 3.1416 divided into 7.06, the lift therefore being .677 inches. Now if we had a spring say 10 inches long, and the pressure the valve was set for was 150 lbs. per square inch, the extra compression of the spring due to the lift of the valve would be

$$\frac{.667 \text{ x } 150}{10} = 10.05$$

so that the total compression of the spring for that lift would be 160.05 lbs. This extra compression would be carried by the increased area of the valve due to the lip.

LEVER SAFETY VALVE

Question.—What would be the weight in pounds of a weight placed on a safety valve lever, the diameter of the valve being 3 inches, distance from fulcrum 3½ inches, length of lever 42 inches, boiler pressure 110 pounds per square inch? The weight of the lever and valve are not given.

Answer.—The weight multiplied by its distance from the fulcrum of the lever, must be sufficient to counterbalance the load due to the pressure on the valve multiplies by the distance of the valve from the fulcrum, neglecting the weight of the lever and valve. Thus the load on the valve will be the area of the valve multiplied by the pressure per square inch, and the distance from fulcrum.

$$110 \text{ x } 3 \text{ x } 3 \text{ x } .7854 \text{ x } 3.5 = 2721.4$$

and the weight to balance this will be

$$\text{Weight x } 42 = 2721.4$$

Putting this in the form of an equation we have, calling the weight W

$$110 \text{ x } 3 \text{ x } 3 \text{ x } .7854 \text{ x } 3.5 = W \text{ x } 42$$

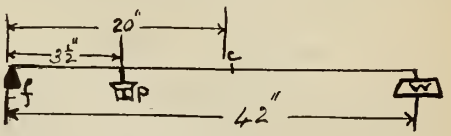
$$W = \frac{2721.4}{42}$$

$$W = 64.79$$

Say 65 lbs.

Supposing that we have the weight of the valve and the weight of lever given, the distance of the centre of gravity of the lever being 20 inches from the fulcrum. The valve weighs 5 lbs. and the lever weighs 10 lbs.

The total upward pressure on the valve will be due to the pressure multiplied by the area, less the weight of the valve, multiplied by the leverage which is 3½. The weight opposed to this will be the weight of the lever acting at the distance of its centre of gravity from the fulcrum, and the weight acting at a distance of 42 inches from the fulcrum. The equation will then be



P = Total Load on Valve
C = Weight of Lever = 10lbs
V = " " Valve = 5lbs

$$(P-5)3\tfrac{1}{2} = (C \text{x } 20) + W \text{x } 42$$

$$W \text{x } 42 = (P-5)3\tfrac{1}{2} - C \text{x } 20$$

$$W \text{x } 42 = (3 \text{x } 3 \text{x } .7854 \text{x } 110 - 5)3\tfrac{1}{2} - 10 \text{x } 20$$

$$W \text{x } 42 = 2703.75 - 200$$

$$W = \frac{2503.75}{42}$$

$$= 59.6$$

Say 60 lbs.

VOLUME AND TEMPERATURE OF AIR

Question.—Kindly explain if the following is right, or if not where I am wrong. I understand a pound of air at 62 F. has a volume of 13 cubic feet, and the absolute temperature is 522 F. Now will a temperature of 522 x 2 1044 F equal 26 cubic feet and double that absolute temperature equal 52 cubic feet. Will the volume of one pound of air at an absolute temperature of 261 F be equal to 6.5 cubic feet. Does steam expand and compress as air does?

Answer.—According to Boyle's law, the pressure and volume of a gas vary in direct proportion, that is pressure x volume equal a constant. This is known as the isothermal law, because the change of volume and pressure are supposed to take place without any loss or gain of temperature. It is expressed pv = constant. Another law, known as the second law of gases, takes into account absolute temperature, and is known as the adiabatic law, or Gay de Lussac's law. It is sometimes express-

ed as "Equal increments of temperature give equal increments of volume at constant pressure, or equal increments of temperature give equal increments of volume at constant pressure."

The law is based on the fact that for every degree of heat added to air in a cylinder, in which is contained a piston which is free to move, the volume of air will increase by 1/460.66 of its volume if the Fahrenheit scale is used, or 1/273 rd of its volume if the Centigrade scale is used.

If we have one pound of air at an absolute temperature of 522 degrees and increase it to an absolute temperature of 1044 degrees, we have increased the heat by 524 degrees. The air being originally at 62 degrees, the ratios of expansion per degree will be 1/522.66. The volume of gas after having a given amount of heat added can be obtained from the following formula:

Initial volume absolute temperature plus acquired temperature, divided by absolute initial temperature = heated volume or

$$\frac{1 \times 460.66 + 584}{522.66} = 2 \text{ volumes}$$

If the volume remains the same and the pressure is increased we get the ratio of expansion per degree 1/522.66. The difference or the heat added is 524 degrees, the initial pressure being 14.7 absolute. Then the ratio, multiplied by the difference in temperature, and the initial pressure will give the new pressure 1/522 x 524 x 14.7=14.7 lbs gauge pressure or 29.2 absolute. Another formula gives

$$\frac{\text{Abs, pres. x difference in temperature}}{\text{abs, temp.}}$$

$$14.7 \;/\; 522 \times 524 = 14.7$$

These two are practically the same and give the gauge pressure. The following gives absolute pressures.

Steam follows the same law as air in its expansion and contraction, but of course there are corrections to be made for moisture etc, and the expansion of air or steam in an engine cylinder does not quite follow either the adiabatic or the isothermal law, but lies somewhere between them.

COMBUSTION PECULARITIES

Question.—I have noticed when firing a coal fire that the flames reach a long way beyond the bridge wall as long as the furnace door remained shut, but as soon as the door was opened the flames would shorten up and disappear. On again closing the door, the flames would lengthen out again. The coal burned when this was noticed was a cheap Canadian lignite. Now can you explain if I was allowing too little air to pass through the furnace door, to complete combustion, so that when the door was shut the flames were the result of late combustion, and when the door was opened the combustion was taking place over the coals?

On another occasion I noticed with wood fires and sometimes with coal fires that I did not have a long flame, but on allowing air to enter the combustion chamber back of the bridge wall a large flame would burst out like a small explosion, and continue as long as the air was admitted. I pulled off the man hole cover on the clean out hole of the combustion chamber on a H.R.T. boiler, the draft drawing in a large volume of cold air, the result being an explosion that drove sparks and flames out of the door with considerable force. To me these two experiences seem to differ and I am at a loss to know which if either was due to incomplete combustion.

Answer.—When burning low grade coal, or coals containing a high percentage of volatile gases, the hydro carbons are distilled from the main body of the carbon, and are ignited if there is sufficient air burning with a long flame. If there is too much air the gases will not be ignited, but will flow on through the combustion chamber and tubes in the form of fine carbon, which becomes soot when deposited. Striking against the heating surfaces of the boiler will cool the gases down below ignition point sometimes. The reason that the flames shortened up when the furnace door was opened was that too much cold air was admitted, and therefore combustion was deferred, this accounting for the disappearance of the flame. Now in the second case it is evident that a large amount of partially consumed gas was present in the combustion chamber and the sudden admission of air enabled it to complete combustion so quickly that it became in the nature of an explosion. This is not an unusual thing. Under certain conditions large quantities of gas are generated in a boiler furnace, much the same as in a gas producer, and the sudden admission of air produces the explosion. The ordinary house furnace, fired with anthracite coal, gives a very good example of this. If the firebox is filled up with coal, until no fire can be seen, and left with dampers partially closed for a while, and the door is then suddenly opened, the gas which has formed on top of the coal will ignite with a sudden puff like a miniature explosion.

DUPLEX PUMP TROUBLE

Question:—I have a duplex pump taking its supply from a Moffat feed heater, the valves and plunger packing are in good order, and the pump works well when the temperature of water is low, but when the water gets very hot the plunger slips about 2 inches of its stroke at the beginning of every stroke. Now this pump has always worked well with very hot water up till now. I might say that the only cause that I can see is that the water ways leading from the cylinder to valve chest are partly blocked with scale. Will this cause the trouble with hot water, and if so how can these be cleaned out. It is difficult to get a toll in on account of the curves. Would it be better to apply boiler compound to the heater, instead of direct to the pump, as there is always a lot of scale in the heater. Would it help to keep the pump clean?

Answer:—Restricted water passages in a pump on the suction side may cause a pump to slip when using hot water. The heater is set above the pump to cause a pressure on the water, thus raising its boiling point, and preventing its vaporisation. However, if the water passages are restricted so that the water cannot follow the plunger up, there will be an effect some thing like wiredrawing, and the pressure on the water will be lowered, thus allowing a small amount of it to vaporise. This will cause the plunger to slip.

It is unusual for a pump to become choked with scale, and in order to clean it would perhaps be best to fill it up with a good strong solution of caustic soda, and leave it stand for as long as possible. The fact that the heater always has a lot of scale, and that the pump also has scale, would seem to point out the necessity of more frequent cleaning out of the heater. The presence of scale in the heater also shows that the heater is doing good work by precipitating scale before the water leaves the heater. The addition of a compound to the water in the heater might be helpful, but it is always necessary to look out for corrosion when doing this.

BOILER COMPOUND FEEDER

By James E. Noble.

A large number of boiler compound feeders have been described. The enclosed diagram shows the old one in a new design. A B being the funnel and filler valve, C and E the tank control valve, G the emptying valve. The tank can be made from large pipe with caps or flanged ends. By opening and closing the different valves, the tank can be emptied of water, filled with compound, etc., without stopping the operation of the feed water pump. The compound does not pass through the pump, therefore if soda ash or caustic soda is one of the chemicals in the compound, the fear of injury to the pump packing or valves is done away with.

By the way what is the matter with the Canadian engineers. Why do they not give your readers some of their power plant experiences. I note that the U. S. engineering journals print many interesting letters in every number. I do not want to "nose" in, but I sure would like to see you try and stir them up a bit. We all know where to get the high class stuff, in the text books. It is only in our engineering journals that we can find the real interesting stuff, and believe me, although I have been over thirty years in the good, old engineering game, the "simple stuff" very often proves more interesting than the "high brow" articles. Not to everyone of course, but I believe to the majority.

Editors Note—We agree with Mr. Noble that many more power plant engineers could contribute interesting experiences if they would take the trouble.

It is only the bringing together of different men's experience that builds up the technique of any profession, from lumbering to doctoring. In contributing to your technical journal you are helping others, as well as yourself.

SAFETY ELECTRICAL APPLIANCES FOR MINES

One of the drawbacks of using electrical apparatus in fiery mines is that explosions taking place inside switch boxes and other apparatus are liable to produce a flame outside, and ignite the gas in the mine. It is practically impossible to make the casing of the electrical apparatus strong enough to withstand the force of such explosion; and if a safety valve is fitted to prevent the cracking of the casing it is likely to permit the flame to escape with disastrous results. A solution of this difficulty has been devised by an electrical company in Great Britain. The cover of the casing is held down by bolts with a spring cover so arrranged that when an explosion occurs the whole cover lifts by not more than one theirty-second of an inch. This lift is sufficient to relieve the internal pressure, but the gases, in escaping through the narrow passage between broad pieces of metal, are cooled sufficiently to prevent the passage of flames. Stringent tests of this ingenious device has proved it to be completely successful.

COAL STORAGE AS AN AID IN COAL BUYING

The coal bill of a public utility is such a large percentage of the total operating cost, and the amount of coal consumed per unit of the delivered commodity is so true an index of the physical condition of the property, that in capably handled plants a great deal of attention has been given to both the delivered price of the fuel and the efficiency of the various power units which make available the energy stored in the coal.

In buying coal, consideration is given to the steaming qualities of the various classes offered and a comparison made of the delivered price, tests are often made to determine the test B.T.U.'s of the product as delivered, and in many cases the price to be paid has been determined upon this basis. In using coal there have been inumerable devices offered which would increase the ability of the boilers to convert the stored energy into heat, and careful design with care in operation has effected wonderful economics in power plant operation.

In general, the buying of coal has been by one of two methods; by contract, wherein the seller agreed to furnish the output of a certain mine, or from a certain district; or by the purchase in the open market of such coal as is needed to keep the plant in operation. The first plan has many advantages, inasmuch as the seller is interested in seeing that the coal arrives at such times and in such quantities as the plant finds desirable, and the purchaser can usually depend upon a steady supply of approximately uniform fuel. The second plan has more of an element of risk, since the price will probably fluctuate coniderably, and the available supply and quality may be subject to great variation.

Variations of the above plans were tried by the Metropolitan Water District of the city of Omaha, but due to the difficulties that were encountered under each, a study was made to evolve a plan which would obviate a part or all of them. It had been noted that at certain times of the year there would be large offerings of the finer grades of coal at prices that were very attractive, and that the price per ton at the mine would bear no relation to the quality of the coal being offered. A plan by which purchases could be made during these periods, and the coal stored until required for use appeared to offer the maximum advantages in economy and also insure an ample reserve for operating peaks and temporary failures of supply. It was known, however, that it would be impossible to store any considerable quantity of the fuel in the ordinary manner due to heating in the piles, and very great consequential loss in heat value. The solution was obvious, and it only remained to provide a storage of such type that heating could not take place, and of such capacity that sufficient coal might be stored to carry of scarcity and resultant high prices.

In 1913 the District constructed the first pit for the storage of coal under water. It was located parallel to the boiler room and at a sufficient distance away as to provide space for two railroad tracks for the handling of loaded and empty cars. Constructed of concrete entirely below the ground level, it had a capacity of fully submerged coal of 2,500 tons, and when piled about 3,500 tons could be stored. It was anticipated that, due to capillarity, this amount of surcharge could be kept sufficiently damp to prevent heating, but this has not been entirely successful, and small areas considerably above the water line have at times fired, making necessary the use of hose lines to cool the coal piled high.

In 1918 a second pit, having a submerged capacity of 6,000 tons, was added, only slight changes in design being made to conform to the experience with the first pit. With the two pits in use it is possoible to store a sufficient amount of coal to carry the plant about five months, and since there is a small tonnage moving to the station at all times it is possible to make practically all purchases during the semi-annual periods of low prices.

The coal is handled from cars to pit by a 25-ton steam locomotive crane equipped with clam-shell buckets, and the same machine takes coal from the pit for filling the hoppers built into the roof, from which the supply is distributed to the boilers by a larry in the boiler room. The same crane also removes the cinders from a pit located at the end of a tunnel passing under the boiler room floor in front of the ash dumps.

Low prices of coal are due in general to two factors. The most important is that there is an excess of screenings at such times of the year as there is a large movement of screened or prepared sizes and with no appreciable market for the finer grades at steam plants having small storage capacity. This occurs in the spring and fall, and it is often possible to obtain very low prices on grades that are highly desirable, and in such quantities as are determined only by the unloading capacity of the receiving plant. The second element is the so-called spot coal. Companies having contracts with the steam users for their requirements must have moving at all times sufficient coal to supply the wants of their customers, and oftentimes sudden warm weather will cause a considerable tonnage to be in transit or actually arrived at destination for which there is no storage

Graton & Knight Leather Belting

Improved methods and the most expert tanners in the world produce leather that is tanned especially for Graton & Knight Standardized Leather Belting. The leather is chosen for the kind of belt it must make.

All users of belting are learning that it is safer, simpler, more economical in every way, to discard complicated belting specifications and buy belting on the basis of Graton & Knight Standards.

Fairbanks-Morse engineers will analyze the requirements of a single machine, or an entire mill, without any obligation, and make their recommendations that will ensure the right belt for the job, whatever it is.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

Canadian Representative: W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA

COAL STORAGES AN AID IN COAL BUYING

(Continued from page 39)

available, and for which there is no sale among those who are generally in the market. Brokers may have many cars due to the same causes, and a resulting weak market forces the spot coal to a price which makes the price attractive to the plant that made the neccesary invesment to enable it to take advantage of such conditions. And the coal dealer or broker is not at all adverse to having a dump, for he may be reasonably sure of disposing of surplus tonnage, even though he must take a loss that would only be greater had he not had such an outlet.

While an accurate check has not been possible with this plan of coal buying, the management feels sure that in the case of each pit the entire cost of construction was wiped out during the first year of operation, and this in addition to the feeling of security that came from having at all times an ample reserve of the plant's most essential supply.—From "The American City."

METALPAC FLEXIBLE ALL-METALIC PACKING

A new metallic packing "Metalpac" has recently been put on the market by the Valve Engineering Co., Toronto. "Metalpac" is composed of continuous metallic sheets fed through a bath of lubricant and crinkled in such a way that the material inside the soft braids of copper, which forms the outside covering, is as pliable and compressible as the outer surface and at the same time indestructable against the highest pressures. All materials used in the manufacture of "Metalpac" are the best obtainable and are treated in the course of manufacture with graphite. When the packing is put in the stuffing box, the graphite is compressed into the packing, making it almost frictionless and giving it a perfectly smooth and permanent bearing surface. The packing, which is made in continuous lengths, is very flexible and will hold together without the aid of fibrous material; the possibility of flaking are therefore eliminated.

"Metalpac" may be used for almost any kind of service such as high pressure hydraulic rams, hot and cold water pumps, ammonia compressors, pumps handling oils and chemicals. For steam service, it is an ideal packing for high pressure steam engine rods and valve spindles, also for throttle valve spindles. "Metalpac" resists heat up to 800 deg. Fah., and can be put up for specially high temperatures; it is therefore quite suitable for superheat steam. "Metalpac" is made in coil ofrm, in all sizes by sixteenths, and can readily be cut to make rings if required. It is recommended only for rods or plungers that are running in line and that are not scored or shouldered.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

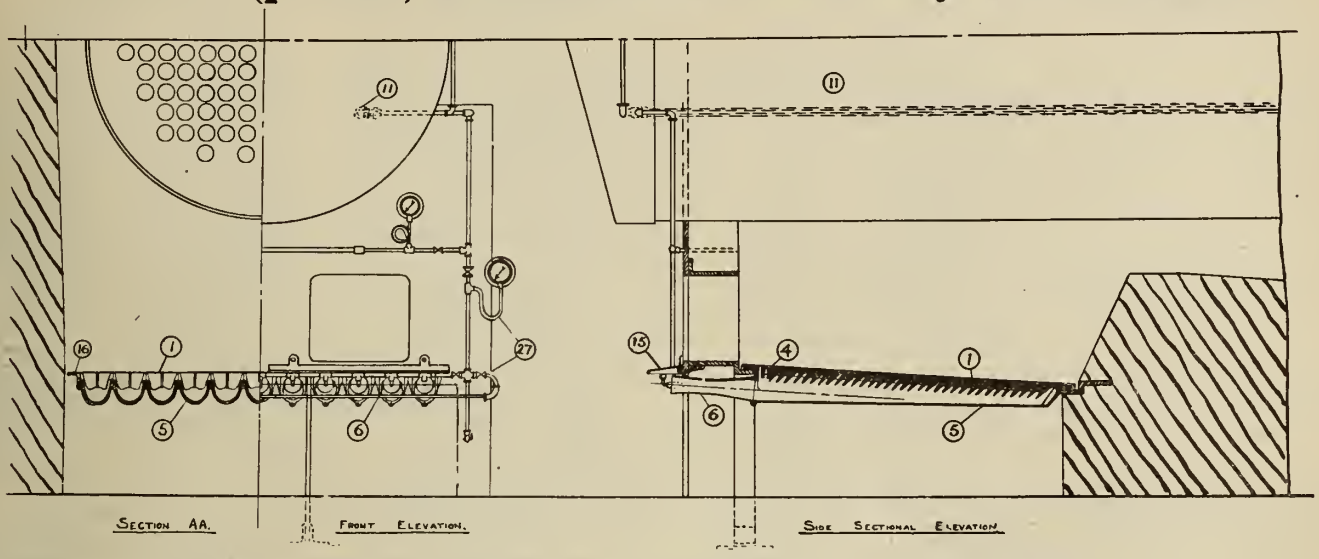
Turbine (patent) Furnace for Externally Fired Boiler



1. Removable fire bars. 5. Air trough. 11. Superheater. 16. Side extension.
4. Locking bar. 6. Air injector. 15. Ash guard. 27. Steam fittings.

Also supplied for internally fired boilers. Write for particulars of the performance of the Turbine (patent) Furnace—using coal slack or coke dust. If you have cheap low grade fuel available let us furnish you with full information at once. Over 1,100 of these furnaces are giving satisfactory service in Britain now.

Manufactured by:

The Turbine Furnace Co. Ltd. London, England

Sole Canadian agent:

If you want something unusual

and it isn't advertised here, the logical thing would be to advertise for it. You'll find that a small ad. in the Classified Advertising Section wll save you a great deal of time in locating men or machinery. Look over these pages and if you don't see what you want, send us your copy to-day for next month's issue.

POWER HOUSE

Classified Advertising Section

143-153 University Avenue
TORONTO

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS WANTED—MALE

ENGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821. Power House. p.2.h.

INSTRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any province, stationary or marine. Terms and particulars on application. Box 13921, Power House. Ph2

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House. P2H

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

POWER HOUSE

Solves the Problem

It is a dominating factor in maintaining power plant efficiency in equipment and service.

Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

HEPBURN

HAND OVERHEAD CRANE

Built with Single or Double I-Beams, in a range of sizes from ¼-ton to 20-ton capacity. Powerful, reliable cranes.

You Need This Handy Crane

IT can save you a lot of valuable time and labor and quickly pay for itself. Send us a plan of your shop, stating the width, the height, the loads to be lifted, and the headroom available. Then we will show you just how the crane will be of indispensable service to you. You will be under no obligation to us in submitting a plan—act now.

A full line of Pumps, Vertical Engines, Compressors, Iron Castings, etc. Enquiries Solicited.

Who was the Third Man?

WHEN the retirement of Sir Robert Borden as Premier of Canada was first announced, three outstanding men were considered as his possible successors. Their names were displayed prominently in every Canadian newspaper. The present Premier was of course one of the men mentioned. Sir Geo. Foster another. Who was the third man? You would remember him no doubt if his name were displayed prominently in the daily press to-day—but he has retired from the political arena, and his name is seldom mentioned.

How easily names slip from the memory when they cease to be given publicity.

There is a lesson here. If you wish your name and the name of your products to be remembered, you must give them constant publicity.

The prudent manufacturer of machine tools, power plant equipment, or industrial supplies of any kind places his name and the name of his products where they will be seen and remembered to best advantage: **in reliable technical newspapers.**

Reliable technical newspapers in Canada are those included as members of Canadian National Newspapers and Periodicals Association. Their circulation is bona-fide and their editorial practice is carefully guarded, in fact their whole policy must conform to the highest standards else they would not be eligible to membership in the association.

Canadian Machinery

Power House

Canadian Foundryman

Marine Engineering

Each of these technical newspapers is a member of the Canadian National Newspapers and Periodicals Association.

Know What You're Doing

Power plant records tell the efficiency of the plant to-day and furnish a means of comparison with the results obtained a day, a month, or a year back. The

VENTURI METER

by indicating, registering and recording the rate of flow to the boiler reveals immediately any condition detrimental to economical boiler operation and furnishes an indelible record of its import and duration.

Bulletin 197 lists in detail the advantages which may be derived from VENTURI METER records, and will be sent on request.

The VENTURI measures hot and cold water, sewage, brine, chemical solutions, oil, gas, air and steam.

Still Best After Test of 8 years

Invariably manufacturers wishing to prove the mechanical merit of anything resort to a rigorous test of some sort.

Abundant proof of the superiority of the Steam Trap Sarco over the costlier, more cumbersome bucket or float type of trap is furnished by two New York manufacturers who replaced float traps with Sarco Traps more than eight years ago.

For eight years the Sarco has been saving steam and money for Walter W. De Bevoise and for Henry Heide of Brooklyn—just two of the many hundreds of manufacturers who have found that the Sarco serves as a valve, a bypass, a check valve and a steam trap all in one.

When steam is shut off at night the Sarco opens automatically and stays open until steam is turned on again. When steam comes on in the morning it forces all the air out and closes the trap, which stays shut until condensation again opens it.

You can install the Steam Traps Sarco for one-third the cost of bucket or float traps and they'll do the same work.

As evidence of Sarco dependability, we quote just a few names of prominent Sarco users:

New York Central Railroad; Pennsylvania Railroad; Erie Railroad; D. L. & W. Railroad; Consolidated Gas Company; Standard Oil Company; Atlas Powder Company; William Cramp & Sons Shipyards, and many, many others.

Let us send you a Sarco on 30 days' trial. If you are willing to part with it at the end of this period, send it back and it will cost you nothing. Write for booklet J-20.

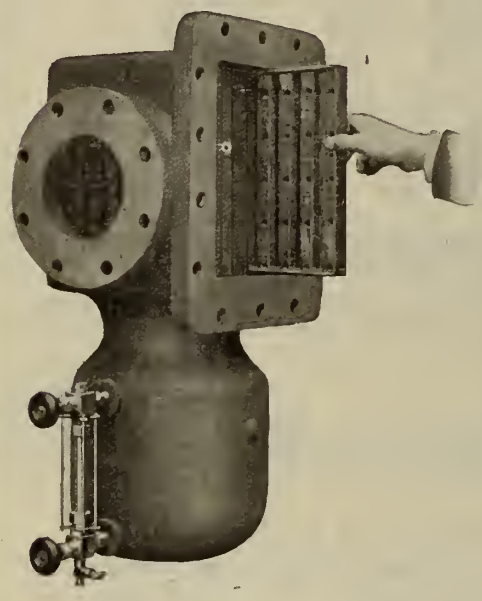
BUNDY Steam Traps and Separators

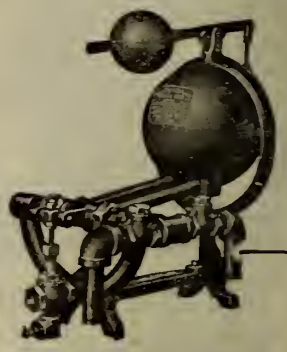


Are the Scientific Answer to Engineering Problems!

THE BUNDY OIL SEPARATOR

is a device perfected to the finest degree possible. In actual service it is the only type that fulfills the following requirements. Insures maximum removal of oil from steam. Prevents steam from again picking up oil. Maintains high efficiency because it is easily cleaned.

Bundy Oil Separators and Steam Traps can be obtained at any of our branch agencies. Drop a line for further particulars.



Return Trap

Bundy Steam Traps can be safely bought on their rated capacity. They are made of cast iron and semi-steel—built for long service. Rigidly tested under actual working conditions.

How Do YOU Judge a Power Plant Investment?

CONSIDERED from any one of five angles, Elesco Superheaters make a good power plant investment:

Fuel Economy:

Elesco Superheaters save from 10 to 20 % of the coal bill.

Additional Capacity:

Elesco Superheaters, at one-fifth the cost of new boilers, increase present boiler capacity 25%.

Reduced Maintenance:

Elesco Superheaters eliminate water hammer and decrease maintenance cost of entire plant.

Increased Revenue:

Elesco Superheaters by adding to boiler capacity increase the revenue of utility plants.

Cost:

Elesco Superheaters quickly pay for themselves in fuel and maintenance savings.

Consider an Elesco investment for your plant. Elesco engineers, after a study of your problems, will give you a recommendation upon which to base your decision.

Uehling CO_2 Equipment

CO_2 Recorders in the Chief Engineers Office keeping him posted on furnace conditions for each individual boiler

MAKE FUEL WASTE VISIBLE

to firemen, chief engineer and manager with

UEHLING CO_2 EQUIPMENT

Then they will co-operate to reduce the waste. This is not theory. Power Plants the world over are saving 10 to 20% of their fuel expense in just this way at a trifling cost.

Complete combustion requires about 15 tons of air per ton of coal. More than this simply chills the fire. Many plants are wasting nearly half their fuel up the chimney simply because the average fireman unknowingly uses too much air. Uehling CO_2 equipment eliminates guesswork and insures maximum fuel economy.

You can estimate YOUR PRESENT FUEL WASTE in dollars and cents. We have a chart for the purpose. It is free. Send for it.

CO_2 Indicator at boiler front to guide the fireman

Uehling Instrument Co. *Combustion Engineers* 2008 Empire Bldg., New York City

D.K.McLaren's

Genuine British Oak Tanned

LEATHER BELTING

D. K. McLaren's Leather Belting is made from the backs of selected hides. The Genuine British Oak Tanning process preserves all the hide's natural strength and gives it a durability and grip that enables us to sell it on a **Service** basis.

Specify D. K. McLaren's Leather Belting in your next order. It is the cheapest in the end.

Quality in Belting!

Quality in the belting you use determines to a great extent the output of your plant. The better the belting the better the output.

D. K. McLaren's products represent a **quality** in belting that is unsurpassed.

It is flexible, gripping, tough—carries all the power that any belting can possibly carry, yet wears long and always gives good service.

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

Waterous

BRANTFORD, ONTARIO, CANADA

Close Regulation

of Steam-Driven Boiler Feed Pumps

Hand control of steam-driven turbine pumps is not successful. The turbine needs a constant load for efficient operation. A sensitive, AUTOMATIC control is the only reliable way to maintain a constant load.

FISHER

Excess Pressure Governor

(Type 4)

is designed to render this accurate, automatic control.

It will maintain a fixed or over-pressure in feed lines regardless of variation in steam pressure. It will do so under all conditions either on the ordinary plunger or steam-driven turbine type of boiler-feed pump. It will work satisfactorily whether supplying one or a battery of boilers.

It is recommended for use in conjunction with automatic feed water regulators.

The valve body is of our standard type of construction; the control is of the diaphragm actuated type.

Valve and seat rings are cast from our special formula, hard phosphor bronze which resists corrosion and wire-drawing.

Write for Bulletin No. 101. It contains full information about the Fisher Excess Pressure Governor and other Fisher Pump Governors.

PUMPS

Pumping Devices similiar to this were, until recently, in occasional use in this country.

Centuries before the Christian Era, the inventive Chinaman had developed a rather efficient pumping device. A bullock turned the wheel. Wooden pegs on the rim of this wheel meshed with the smaller wheel on the long shaft. A heavy chain, equipped with buckets, descended into the well and drew forth the water which was carried to the gardens and fields.

All things considered, this was a fairly efficient device. Modern American-Marsh Pumps are **wholly** efficient. They can always be depended upon for reliable, effective, powerful service.

Write for Bulletins.

New Truths and Old Fallacies

HIGH SPEED

Upon a babbitt metal's self-lubricating quality also depends its ability to stand up under high speeds because of the increased rubbing surface and liability to metallic contact.

Where speed and high pressure are combined, a bearing is tested to its maximum capacity, as was the case in the test of Magnolia Versus Genuine Babbitt, by Doctor Torrey.

This Magnolia quality fits it peculiarly for use on high-speed, heavy-duty machinery, such as planers, shapers and other woodworking machinery sometimes running at speeds as high as 5,000 R. P. M. Three to five years in this service is common, and in one case reported to us, the bearings have been running fifteen years and were then still going in good shape.

On light running bearings there is probably no speed limit to the capacity of Magnolia.

Professor John Goodman, before mentioned, says of Magnolia, in this connection: "Under heavy pressures and high speeds, I find that it is very materially superior to any other metal on the market that I have tested, and under such conditions the friction is much lower and above all the metal never seizes."

The frictional co-efficient invariably denotes the extent of a babbitt's self-lubricating quality and it is useless to expect to find that quality combined with a high frictional co-efficient. The co-efficient of friction is the ratio of the force required to produce motion. It is also defined as being the ratio obtained by dividing the entire force of friction by the normal pressure.

A Good Boiler

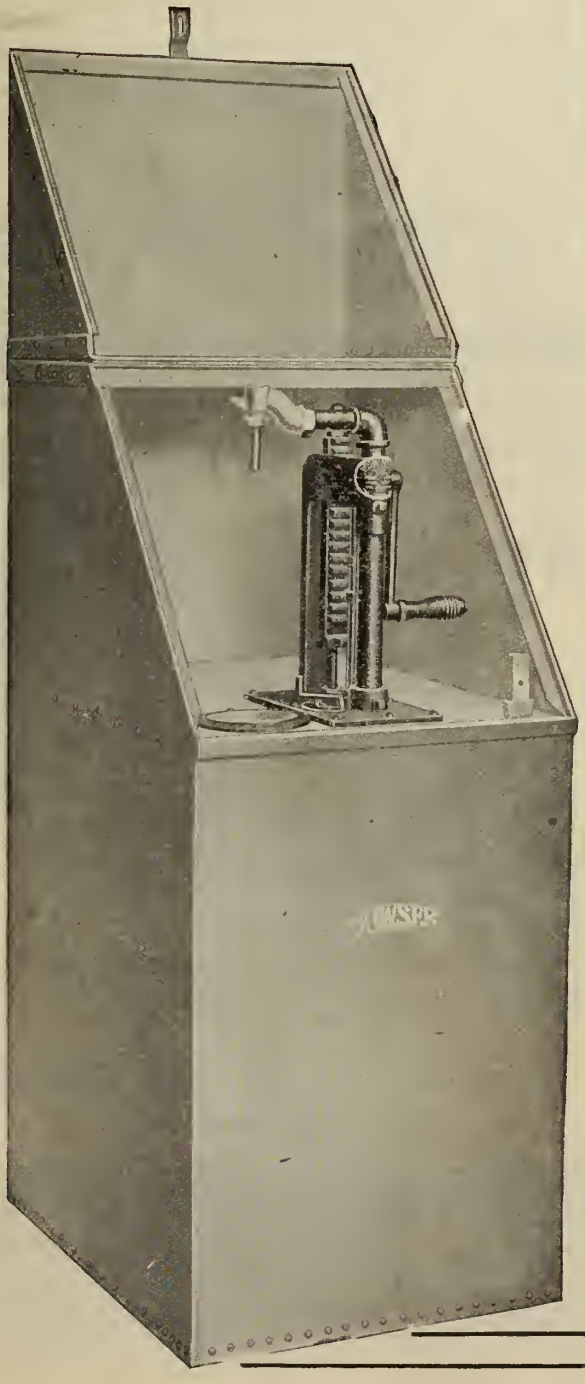
Will make its economy and efficiency very quickly felt. With our Boiler prices where they are today it does not pay to put up with out-of-date, worn out Boilers. Let us quote you surprisingly low figures. Delivery service excellent now.

We build Boilers for Power and Heating uses, in all types, all sizes.

Get Better Lubrication at Less Cost

Install Bowser Oil Handling Equipment

Incorrect lubrication will take its toll of your machinery slowly but surely. Undue depreciation is bound to result from the friction caused by gritty oil. And no matter how good the oil you buy, you cannot have correct lubrication unless it is *kept clean.*



By storing oil in Bowser leak-proof and dust proof Tanks, you will keep *your* oil clean and give better lubrication to your machinery. The Piston-Type Pumps deliver exactly the amount required directly into the distributing container, eliminating waste. Bowser centralizes your oil storage, making it easily accessible. The safety of Bowser is also an important element to consider.

Not once in 35 years has Bowser Equipment started or contributed to a fire.

Whatever your requirements, there is a Bowser to meet them. Ask us.

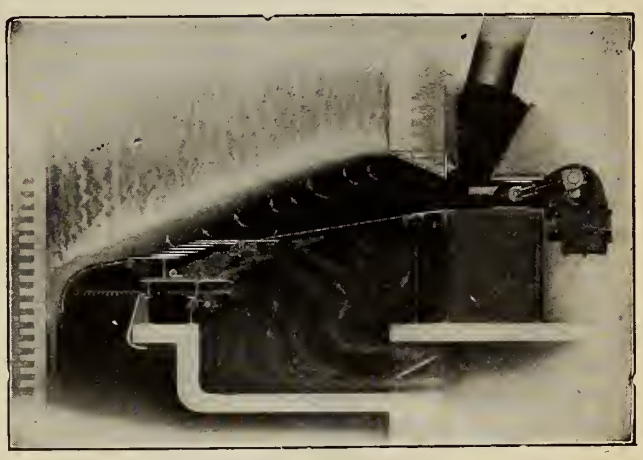
High Efficiency and Capacity



Riley Stokers at the McKeesport Tin Plate Company are carrying daily an average load ranging from 230% to 265% of boiler rating. Here 8-retort stokers are installed under 606 H. P. boilers.

CO2 readings indicate the efficiency being obtained. Taken at five minute intervals over a period of thirty days these have averaged slightly over 14 per cent.

The Riley moving grates are a big factor in obtaining efficiency and capacity for:

1. They keep the fuel bed always active and even.
2. The shearing action of each line of grates slices any large clinkers that may form and pushes them to the dump, thereby keeping the fuel bed clean.

To learn more of exclusive Riley features ask for Catalog HR-11.

For information on Murphy Automatic Furnaces for small boilers, see Sept. 20 advertisement, or send for Murphy Furnace Catalog HM-10.

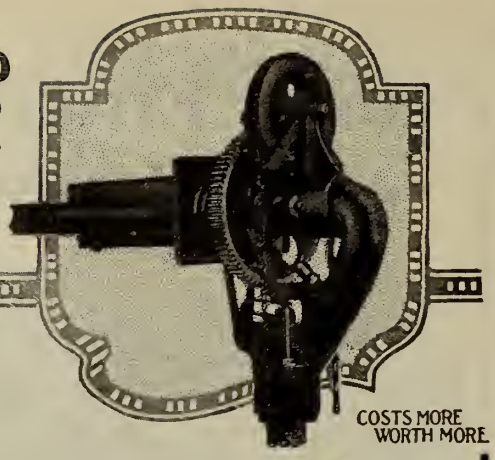
DIAMOND
VALV-IN-HEAD
SOOT BLOWERS



DOLLAR FOR DOLLAR!! *POINT FOR* POINT!!

Dollar for dollar the Valv-in-Head soot blower is a tremendously better investments than the independent valve soot blower.

AMONG THE VALV-IN-HEAD ECONOMIES ARE:

1. **Steam for Operation:** Saving of 50 per cent.
2. **Labor for Operation:** Saving of 50 per cent.
3. **Pipe, Valves and Fittings:** Saving of 66-2-3 per cent.
4. **Maintenance:** Saving of 25 to 50 per cent.

These savings alone offset any extra first cost of the Valv-in-Head system. Once installed, the new blowers pay for themselves several times over each year.

Now note some of the outstanding mechanical advantages:

5. **Valve Design**—time of opening and closing exactly adjusted to soot blower operating conditions being slower than the standard quick-opening valve and faster than the standard globe valve, thus solving a problem of long standing.
6. **Valve Body**—heavier and stronger than that of high grade valves for equal pressures and temperatures.
7. **Tightness**—unless operator makes two trips, to close globe valve, one to shut off line (while valve is hot,) and second to tighten valve (after it has cooled and contracted,) the globe valve tends to leak as wire drawing and erosion take place. With Valv-in-Head system, valve is tightly closed at all times. Fewer joints and fittings with Valv-in-Head system mean fewer opportunities for leaky lines.
8. **Control**—steam may be intermittently discharged over two or more arcs in revolution. Arc or arcs of steam jets within boiler invariably cover exact predetermined limits. Speed at which blower element may be revolved is so controlled by reduction gearing as to make improper operation impossible, owing to the fact that there is an audible signal to indicate valve open.

There are dozens of other mechanical points. Why not let us tell you about them.

Every boiler needs a mechanical soot blower and you will save money by buying the best. Diamond Valv-in-Head blowers are adapted to all types of water tube boilers. On request our Service Engineer will go over your existing soot blower installation and advise whether it can profitably be replaced with the Diamond Valv-in-Head system.

Ask for Your Copy of Bulletin 287 Describing the New Blower.

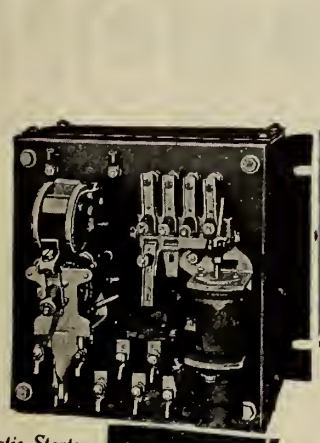
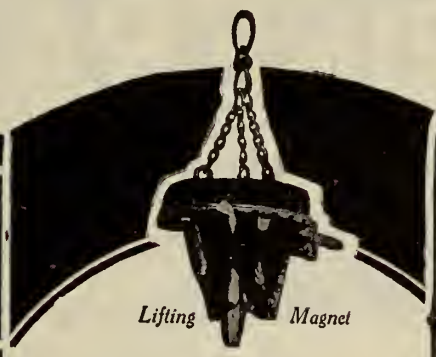
CUTLER-HAMMER



Automatic Starter



Lifting Magnet

Compensator

Magnet and Control Devices

¶ Cutler-Hammer Lifting Magnets and Magnetic Separators have proved of exceptional value in the mining field, in steel mills and in many other industries for lifting and separating metals. The Magnetic Clutch and electrically operated Brake, used primarily in steel and rubber mills and for crane control repectively, are widely applicable to many industries where the gradual engagement or adequate braking of a load is desirable.

¶ In electric controlling devices of all kinds Cutler-Hammer is the recognized standard of dependability, whether for fine speed adjustment of a machine, extremely close voltage regulation, the wonderful light dimming and colour effects in a modern theatre, or the automatic control of heavy loads or other special operations.

¶ Details and recommendations of suitable Cutler-Hammer apparatus for your control problems are available at our branches.

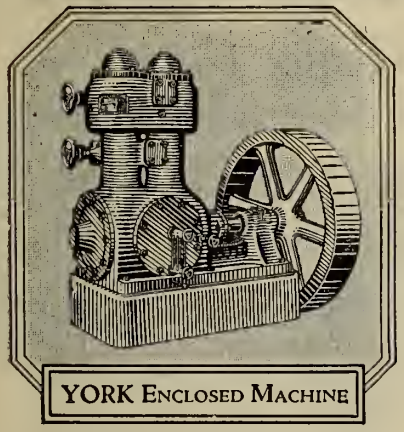
YORK



RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

P⊕H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend P⊕H Lap Joint.

No Disarmament Here

WHATEVER the conference decides to do about armies and navies, industry must maintain its warfare on production losses. And one of the most important defenses in your plant is the protective armament on your refrigerated lines.

The loss of refrigeration from uninsulated lines is so great that the saving effected by applying Nonpareil Cork Covering will pay for their insulation in a year or less—an annual return of 100% that can be depended upon for years to come.

Not only does Nonpareil Cork Covering afford the maximum protection but, given reasonable care, it will retain its insulating value indefinitely. Protected, internally by its binder of natural gum, and externally by its ironed-on mineral rubber finish, Nonpareil Cork Covering is impervious to moisture. Hence, it is proof against any deterioration in efficiency or structural strength. It "lasts longer than the pipe."

Do you know how much you lose from uninsulated lines? How to figure the loss and how to stop it is fully explained in the 64-page book, "Nonpareil Cork Covering," which will be sent you, free on request.

This Bulletin Points a Way to Boiler-room Economy

The crying need of the world to-day is ECONOMY—and still MORE ECONOMY—coupled with greater efficiency in production.

There is a host of ways to arrive at the much desired result, of course.

One of them—a tremendous help in reducing boiler-room losses—is the Vulcan Soot Cleaner. It reduces stack temperature, increases steam capacity and production, and decreases fuel consumption.

Send for a Vulcan Bulletin and let it show you how and why Vulcan Soot Cleaners are a vital necessity in the modern boiler-room.

The Bulletin shown describes the Vulcan Soot Cleaner for Stirling boilers. Other Bulletins are: No. 541, for B. & W. boilers; No. 547, Wickes; No. 550, Connelly, Badenhausen and Erie City Vertical; No. 552, Edge Moor; No. 556, Keeler, Geary and Union; No. 534, Return Tubular. Ask for the one for YOUR boilers.

Bailey Fluid Meter
Type C-2

Sometimes a Boiler Just Quits

But the Others Cover Up the Deficiency

Where a number of boilers are all in operation, how are you going to tell which is the non-productive one? How will you know which one to eliminate or replace?

A "Bailey" will tell you

By the use of Bailey Meters you accurately and speedily tell the individual performance of each boiler and can apportion your steam charges accordingly. You can tell whether Department A used more steam than Department B. You can check the steam flow to your turbines, heaters, and all other process work. Bailey Fluid Meters are simple, convenient, and easily read. They seldom get out of order.

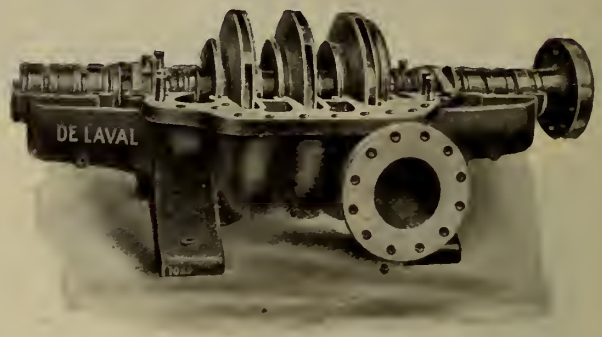
Centrifugal Pump Perfection

Like perfection in any of the many difficult arts which look easy to the outsider, perfection in the building of centrifugal pumps is compounded of an accumulation of exact knowledge and long and extended experience.

The unequalled efficiencies obtained by De Laval centrifugal pumps (one recently showed over 86% under official test) have been attained only through consistent experimenting and testing. De Laval centrifugal pumps are carefully tested as to capacity, efficiency and running qualities, and it is thus possible for our Engineering Department to note the effects of every change in design.



De Laval multi-stage pump with casing cover removed.

High efficiency is further effected by the use of De Laval labyrinth wearing rings, which reduce to a minimum the leakage from the discharge to the suction chamber.

Every De Laval centrifugal pump is fully guaranteed. If you will state the proposed conditions of operation, our engineers will promptly give you the benefit of suggestions based upon an extensive experience, and will quote results which we are prepared to guarantee.

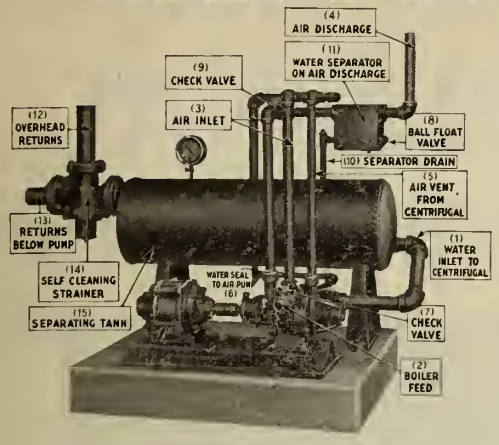
44-6 Lombard Street, Toronto, Ont., Canada

If it isn't BETSON'S it isn't Plastic Fire Brick



Referring to Fig. 3, the heating returns, air and water,, pass through the self-cleaning strainer (14) into the separating tank (15). The water falls to the bottom of the tank (15) and passes into the centrifugal through the pipe (1), driving out the air through the pipe (5). As soon as the centrifugal is full of water it begins to pump and forces the condensation into the boiler through the pipe (2), emptying the tank (15). The centrifugal now stops pumping because it cannot handle air, the check valve (7) preventing a back flow. The power required to drive the centrifugal is closely proportional to the quantity of water handled. It takes almost no power when it is not pumping.

The air is rapidly exhausted from the system by the air unit, which is connected to the top of the tank 15 by the pipe 3. The small amount of water necessary to keep the air end primed is obtained from the bottom of the separating tank 15 by means of the pipe 6. This water is discharged with the air and is thrown to the bottom of the separator 11 and automatically returned to the tank 15 through the pipe 10, the ball float valve 8 preventing any air from re-entering the system.

JENNINGS

HYTOR VACUUM HEATING PUMP

FOR return line heating systems, dryer exhaust systems in paper mills, or other vacuum work where large percentages of liquids have to be handled with gas.

The Treatment of Boiler Feed Water

In This Article, Which is the Third on this Subject, the Author Considers the Artificial Zeolite Systems, and the Evaporating Methods. He also Gives Figures, Illustrating the Investment Side Of the Question

By ROBERT JUNE

OUR PRECEDING articles have dealt with the various impurities in boiler feed water, the resultant operating troubles, and we have also considered the use of boiler compounds, boiler metal treatment and water softening plants, as a means of overcoming our difficulties. Several important methods of water treatment have yet to be considered.

The Zeolite Water Softening Method

All of the troublesome calcium and magnesium in boiler feed water may be removed by passing the water through a bed zeolite. Zeolites are silicates which possess the valuable property of effecting a rapid exchange of the sodium, which they contain, for calcium and magnesium in the water. As hard water comes in contact with zeolites this exchange takes place instantaneously, harmless sodium salts being formed and the hardness remaining in the zeolite. The action is a chemical exchange, and takes place in the cold. There is of course a definite limit to the quantity of sodium which may be exchanged for calcium and magnesium in the water, this limit depending upon the total amount of exchangeable sodium in the zeolites, which is regulated by the sizes of the zeolite bed.

When the limit of exchange has been reached, the zeolite bed is regenerated by passing through it a brine composed of common salt. As the reverse of the softening exchange takes place, sodium replaces the absorbed hardness and the hardness forming constituents are carried off to the sewer as a clear solution. The zeolite bed is then ready to treat another batch of hard water. As the exchange involves no loss of the zeolite, the same bed may be used for an indefinite number of years without the addition of a new supply of zeolite.

The use of zeolites for softening water for industrial and domestic purposes was introduced in the United States about ten years ago by the Permutit Company, who use the trade name Permutit in marketing their various products.

The design of any particular zeolite system will of course depend upon the chemical composition of the water to be treated and the maximum hourly and total daily amounts. The area and depth of the zeolite bed must therefore be determined in each individual case after the water has been analyzed and the desired capacities determined. Many other factors are also involved as zeolite equipment is frequently installed in combination with other apparatus such as iron removal apparatus, aerators, lime-soda pre-treatment apparatus, etc., depending upon the amount and variety of impurities that it is desired to remove from the water, and other operating conditions.

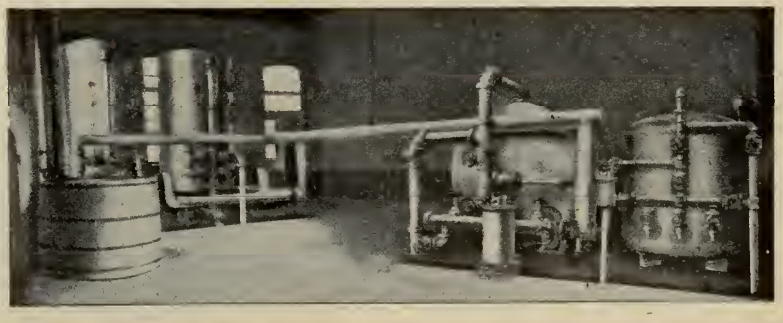
In the main, however, satisfactory operation is obtained through the use of a zeolite water softener alone. The rate of softening through zeolite bed is normally about the same as through a rapid sand filter, and in the case of fairly soft waters it may have as much as double this rate, for the reason the equipment takes up a comparatively small amount of floor space in proportion to the quantity of water handled.

In the design of this equipment the water is passed through the zeolite bed. Operating valves are provided so that during the process of cleaning and regeneration the flow may be reversed, thus thoroughly loosening and carrying off all sediment that has been deposited in the zeolite bed during the process of softening as well as the calcium and magnesium impurities that are removed by the regeneration process. These impurities are all discharged to the sewer and by reversing the flow in this manner any tendency to form channels in the zeolite bed is removed.

When continuous night and day supply of water is desired it can be accomplished either by arranging for storage of the softened water or by means of the two zeolite softeners in parallel that permits the regeneration of one while the other is softening water.

The regeneration is accomplished by introducing into the water softener a brine solution that contains exchangeable sodium in excess of the amount of calcium and magnesium that is to be removed from the zeolite bed. This solution percolates hrough the zeolite bed forcing out the calcium and magnesium to the sewer and continuing until all particles of zeoli e have been regenerated. The length of time required for regeneration is governed by operating requirements as it may be accomplished in twenty to thirty minutes, or over a period of six hours or more.

If a single zeolite softener unit is operating on a ten hour day it can be most advantageously regenerated by occupying the idle time over night as it is obvious that the more slowly a zeolite bed is regenerated, the more completely this function will be performed. If there are two softeners in operation working



The 200,000-gallon Permutit Water Softening and Clarifying System of a Manufacturer in Rensselaer, New York, Which Operates on a Four-Grain Water From the Hudson River.

alternately the period for regeneration is best arranged to occupy the full softening period of the unit that is in operation. For other operating conditions, other periods of regeneration may be most suitable, it being kept in mind that the longest periods of regeneration give the best results.

Because of its positive character and its flexible adaptability to all operating conditions, zeolite water softener offers a real solution to feed water problems. Boilers and auxiliary apparatus fed with zeolite softened water are found to be maintained permanently clean. Zeolite water softening apparatus because of its simplicity and automatic features has a the cheapest commodity existing, its cost for regeneration purposes is equally low per thousand gallons of water softened. It has been shown that a return of 50% on the investment may be expected from the average zeolite water softening installation for boiler feed purposes and there are many recorded instances of installations in textile mills, paper mills, laundries, soft drink manufacturies, canning factories, etc., in which the softened water is used for manufacturing processes, that investments in zeolite equipment have made a return of several hundred percent. For this reason and because of the large amount of capital that is necessarily tied up in boilers and auxiliary equipment it may be seen that the consideration of zeolite water softening apparatus may prove to be a very profitable move on the part of the manufacturer.

Zeolite Plants from an Investment Standpoint

The figures in Table 1. have been tabulated for a small steam plant operating three 200 H.P. boilers, average load 500 B.H.P peak load 750 B.H.P. Make up amounts to 50 per cent of the total boiler feed. This data is from average figures based on the experience of Borromite users.

TABLE 1

(Coal at $5.00 per ton in the firebox)

Cost of Operation with Scale.

(1)—Make-up water is 12 grains per gallon in hardness. Scale in 3 weeks is 7-64 in. thick—average about 1-16 in.; loss in heat is 10 per cent. Boilers opened for cleaning and inspection every 3 weeks	
(2)—One of the 3-200 H.P. Boilers is cleaned each week. Labor cost—2 men, 2 days at $5 per day, per annum	$1040.00
(3)—Coal for heating the water drained out of boiler and that to fill boiler after cleaning—1-4 tons x 52 weeks x $5.13 tons;, per annum	65.00
(4)—Investment in a Boiler and Stoker, $5000. Since a boiler is out of service 2 days each time it is cleaned, this means with 3 boilers there are 104 days one is out of use in a year ($5000 x 7 per cent x 104) ÷ 365 = interest loss on investment	99.00
(5)—Excess blow-down over normal, to eliminate sludge from use of boiler compound, and hard water is 2 gauges extra per day or 310 gallons total for three boilers. (310 gal x 8.3 lb x 210 degrees [rise in temperature] x 365 days x $5.00) divided by (8400 (B.T.U. per lb of coal; x 2000 lb;—	58.70
(6)—New tubes, 12 per boiler or 36 at $10.00 per annum	360.00
(7)—Coal, 1400 tons at $5.00 per annum	7000.00
Total	$8622.70

SUMMARY:

Cost of operation with scale	$8622.70	
Cost of Scale-less operation	$6416.50	
Gross annual saving		$2206.20
Cost of Borromite Softener for plant of this size—$3000.00		
Interest and depreciation at 15 per cent	450.00	
Cost of operation, 26 tons salt at $10.00	260.00	710.00

TABLE 1

(Coal at $5.00 per ton in the firebox)

Cost of Scale Less Operation with a Borromite Water Softener

(1)—Make-up water is 0 grains per gallon in hardness. No scale is formed. Boilers opened for inspection once every 12 weeks	
(2)—No scale, no labor cost for cleaning..per annum	$0000.00
(3)—Coal for heating the water drained out of boiler and that to fill after inspection 1-4 ton x 12 months x $5.00 (3 tons) per annum	15.00
(4)—Investment in a Boiler and Stoker $5000. Since a boiler is out of service one day each time it is inspected, this means with three boilers there are 12 days one is out of use in a year, ($5000 x 7 per cent x 12) ÷ 365 = interest loss on investment	11.50
(5)—No excess blow-down with clean soft water	00.00
(6)—New tubes, 3 per boiler or 9 at $10.00 per annum	90.00
(7)—Coal 1400 tons—10 per cent (140 tons) or 1260 at $5.00	6300.00
Total	$6416.50

SUMMARY (Continued)

Gross annual saving	$2206.20
Less interest and operating charges	710.00
Annual "Pay-Balance," Net	$1496.20
Return on investment in Softener	50 per cent

Distilling Plants and Evaporators

Distilled water for boiler feed is in successful use in many power plants. It is first produced by vaporizing the raw water in an evaporator, and then passing the steam to a condenser, or preferably into the boiler feed heater, where it is condensed by means of the feed water entering from the main power plant condenser.

The Reilly Submerged Type Evaporator, consists, essentially, of a closed shell for holding the raw water, into which are introduced a number of steam coils. Live steam from the boiler, sometimes at reduced pressure, or auxiliary exhaust steam, is passed into the coils where, upon condensation, it gives up its latent heat to the raw water, thus vaporizing the raw water.

In order to effect greater economies in operation "double effect" distilling plants are frequently used. In this type of plant steam from the "first effect" evaporator is condensed in the heating coils of the "second effect" evaporator, the vapor from the "second effect" evaporator being condensed in the usual way.

As a matter of general practice it will be found that the production of the "single effect" distilling plant is approximately one pound of distilled water for one and two-tenths pounds of steam supplied to the evaporator coils, whereas the "double effect" distilling plant will produce about one pound for each seven-tenths pounds of steam supplied to the "first effect" evaporator coils.

Therefore, in choosing between the "single effect" evaporator and the "double or multiple effect" evaporator, consideration must be given to these facts.

As a matter of general practice it will be found that the production of the "single effect" distilling plant is approximately one pound of distilled water for one and two-tenths pounds of steam supplied to the evaporator coils, whereas the "double effect" distilling plant will produce about one pound for each seven-tenths pounds of steam supplied to the "first effect" evaporator coils.

Therefore, in choosing between the "single effect" evaporator and the "double or multiple effect" evaporator, consideration is to be given to first cost on the one hand, and to the economies effected by the use of the compound equipment on the other. From a dollars and cents standpoint it is usually more economical and better engineering practice to use the "double" or "multiple effect" system.

Evaporating plants are generally designated as "low heat" level or "high heat" level. In the "low heat" level plant the evaporators may be operated with boiler steam at full or reduced pressure, or with auxiliary exhaust steam at a pressure as low as two pounds. The latter installation, where auxiliary exhaust steam is used, is apt to be quite expensive however, owing to the large volume of steam handled and to the fact that evaporation must take place under a vacuum, thus requiring vacuum pumps, etc.

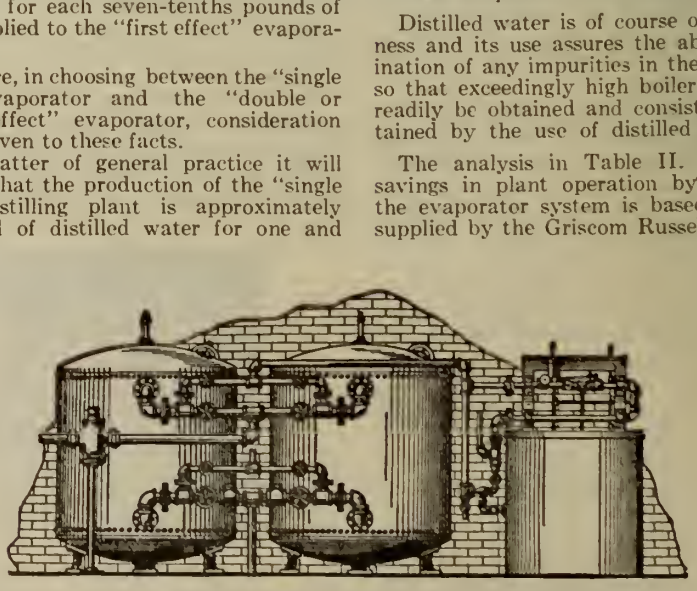
The "low heat" level evaporator is usually preferable where economizers are used, and it may also be a profitable investment where there is considerable auxiliary exhaust steam.

Where there is say 10 per cent or more of make up water required and where economizers are not used, it will generally be found that the "high heat" level evaporating system is the most satisfactory and economical. As the name indicates, evaporation in this system takes place at comparatively high temperatures and pressures. As the steam consequently passes from the evaporator at high temperatures it can be condensed in a condenser, using circulating water at coreespondingly high temperature.

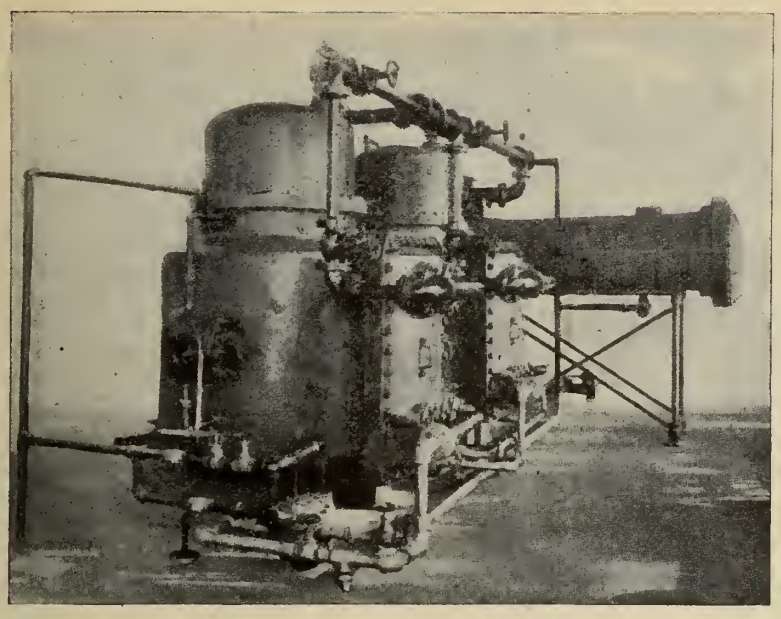
In the Griscom-Russell Company "high heat" level condenser the boiler feed is pumped from the boiler feed heater through the "high heat" level condenser or condensers, on its way to the boilers. Drains from the "high heat" level condenser and from evaporator coils are passed to the boiler feed heater. With this system the boiler feed water reabsorbs all heat given up in the evaporating coils with the exception of the small amount lost in radiation and the evaporator blow off.

Distilled water is of course of zero hardness and its use assures the absolute elimination of any impurities in the feed water, so that exceedingly high boiler ratings can readily be obtained and consistently maintained by the use of distilled feed water.

The analysis in Table II. of probable savings in plant operation by the use of the evaporator system is based on figures supplied by the Griscom Russell Company.



A Borromite 2-Unit 24-hour, Continuous Service Type Softener.



Griscom-Russell High Heat Level Evaporator Plant Simple Two Effect.

TABLE II

Net hourly boiler evaporation . . . . . 150,000 lbs
Net hourly boiler feed make-up. . . . . 15,000 lbs
Net hourly boiler blow (without evaporator system) . . . . . 7,500 lbs
Boiler steam at 200 lbs gauge, saturated
Hot well temperature . . . . . 90 d'g's F
Raw water which would be used for evaporator feed . . . . . 63 degrees F (Brackish)
Auxiliary exhaust steam, 13,600 lbs per hr at 0 lbs g
Boiler evaporation, 9 lbs of steam to 200 lbs g per lb of coal (Useful heat per lb of coal equals 10,513 B T U)
Cost of coal . . . . . $4 00 per 2000 lbs
Cost of present make-up water $1 00 per 1,000 cu ft (Purchased from Public Water Works) . . . 63 degrees;

BOILER BLOW—

Will be practically eliminated
Savings per year—7,500 x 330 x 8,760 x $4 00
10,513 x 2,000 $4,124 00

BOILER TUBE HEAT TRANSFER—

Will be increased sufficiently to save approximately 5 per cent of coal bill
Saving per year—150,000 x 8,760 x 05 x $4 00.
9 x 2,000 $14,600. 00

BOILER TAKE DOWN—

Will be largely eliminated
Estimated saving per year $1,000 00

BOILER MAINTENANCE—

Tube replacements, etc, will be greatly reduced
Estimated saving per year 500 00

COST OF PRESENT MAKE-UP WATER—

Will be eliminated
Saving per year—15,000 x 8,760 x $1 00
62 5 x 1,000 $2,100.
Total yearly savings in plant operation $22,324 00

Charges Against Evaporator System

FIRST COST—

Approximate total cost of Evaporator System including piping, lagging and erection $26,900.00

RADIATION—

Approximate total radiation surface—800 sq ft
Assuming radiation—60 B T U per sq ft per hr
Heat losses per hour—800 x 60—48,000 B T U

EVAPORATOR BLOW—

With the system proposed, evaporator blow will be about 2,500 lbs per hour at 212 degrees F (Temp of raw feed 63 degrees)
Heat losses per hour—2,500 x 149—373,500 B T U
Total heat losses per hour—421,500 B T U
Cost of these losses
per year . . . . 421,500 x 8,760 x $4 00
10,513 x 2000 $703 00
15 per cent per year on $25,900 . . . . . $4,035 00

COAL STORAGE ECONOMY

That there are no unsolvable technical difficulties in the way of the plan recently suggested by President Harding to the American Mining Congress whereby the production of coal be made more uniform, and conditions of unemployment ameliorated and seasonal periods of depression largely obviated in the mining industry by the provision of storage reservoirs in which coal could be stored in quantity by large consumers and producers, is declared by Dr. H. Foster Bain, Director of the Bureau of Mines. Careful analysis may show an extremely slight loss in the heating value of most bituminous coal after storage for a considerable period, says Dr. Bain. This loss, however, is very much smaller than is commonly supposed by the public, and in burning the coal little or no difference can be distinguished. Certain coals have an extra market value when carefully sized; handling these coals in and out of storage causes some breakage and may lower slightly the market value of particular coals, but this loss in value relates largely to the availability of the coal for certain classes of equipment and for certain uses, rather than to its actual heating value.

Spontaneous combustion in coal, the most troublesome factor in handling large storage piles, can be prevented, if proper methods of storage and supervision are adopted.

"The adoption of a general policy which would provide reservoirs of bituminous coal to be drawn upon in times of great demand or of low production is entirely a commercial question," continues Dr. Bain. "If the producer, or the dealer, or the large consumer, could produce or buy coal in the spring or summer for a price low enough to justify the cost of putting coal in storage and its rehandling, minus a fair insurance rate that would be gauaranteed a continuous supply in time of need, storage would become common."

"This lower seasonable price of coal could be brought about by concessions on the part of the miner, the mine operator, and the railroads. For the sake of obtaining more regular employment, the miner might accept a lower wage or rate in certain seasons of the year, although this is doubtful; but the mine operator might accept less profit during the same periods in order to keep up his production. Steady and regular mine operation at capacity production always means lower production costs, as compared to with intermittent operation and lessened production. Overhead expenses —taxes, interest, management, together with the expense of keeping the mine in proper working condition—all go on, whether production is light or heavy, or has entirely stopped. The railroads could assist by accepting a lower freight rate on coal moved in the spring and summer.

"The small individual consumer, especially in the cities, often has inadequate storage space. Storage at the mine may allow a steady working-day in time of shortage of cars but will not ensure steady seasonal operation. Again, large scale storage at the mines does not do away with the difficulty of transportation often experienced to the points of consumption. Moreover, a great many mines are in a hilly or mountainous country, where but little, if any, space is available for large storage capacities. The proper place, therefore, for storage on a large scale is at or near points of consumption.

"This latter kind of storage involves the use of a large plot of ground, as coal stored 10 feet high allows slightly less than 10,000 tons storage per acre. The purchase and installation of mechanical coal handling devices and systems would also be necessary.

"There are in existence numbers of Americans who have successfully designed and built many coal storage systems for public utilities and other corporations which at present store considerable quantities of coal. In addition, there should be a fuel engineer in charge who has a practical and technical knowledge of the way in which different kinds and sizes of bituminous coal will probably act in storage, and who knows the engineering features vital to the economical handling of coal. These three factors are today easily obtainable in the United States; their purchase and employment involve large capital expenditures on which an adequate return must reasonably be expected.

"When, at such a projected storage plant or yard, coal can be purchased at a delivered price sufficiently low to secure a fair return on the investment, after adding the operating costs of storage and rehandling, then coal storage yards will become established near all of the points of heavy consumption and the present seasonal variations will be largely avoided.

"There are no mysteries or unsolvable technical or mechanical questions that block the way to the adoption of a general policy of storing bituminous coal, in either large or small quantities."

Some Experiences with Hydraulic Accumulator

The Author Relates Some of the Difficulties Encountered When the Hydraulic System is Called on to Supply a Heavy Overload, and the Methods Adopted to Keep the Plant Running

By J. A. McGillivray

A LARGE number of engineers in the Steel Plants of Canada will look back to the period of the War and the time when munition making was at fever heat, with mixed feelings. Many could, if they would, tell of worth-while stunts that they had to pull off at a moment's notice in order to keep the old mill going. Certainly there is none who will give the soldier, "Jack," "Tommy" and "Sam," more credit for the glorious stunts pulled off in the mud of Flanders than the engineer, but there was glory in it for them if nothing more. But the engineer had his Flanders mud in the accumulator pits, packing a rod maybe with the water streaming down his arms and back, trying to keep his footing on greasy timbers, endeavoring to raise into place a gland that weighed 200 or 300 lbs., that wouldn't enter on studs that were forced out of true by the swaying and bumping of accumulators that were carrying pressures of 1500 to 3000 lbs. to the sq. in. supplying pressures and gap-riveters operated by near-madmen who thought of nothing but tonnage. (They were usually paid piece work).

If his Flanders mud wasn't there he might be found wallowing on his belly in it inside of a hot boiler that had to be in the line in the morning, or maybe he was waiting for zero hour (12 midnight when the munition workers took 20 minutes for lunch or to change dies), with a spanner in his hand to go over the top with a blown out gasket or a broken stud in a plunger packing gland. There was damn little thanks for it, let alone glory. But just the same they were days of real sport—eh, Old Timer?

A recent visit to my old hunting ground brought some of those almost forgotten memories back again. Therefore, I will set down a few of the incidents that may interest others who are still having their Flanders mud, and who knows but that some of the old timers who can talk but won't will change their mind and give us a yarn.

During the early Fall of 1914, about the time the late Sir Sam Hughes was making history at Valcartier, Colonel Tom Cantley was making history in the Nova Scotia Steel Mills, experimenting at shell forging and installing hydraulic presses. The hydraulic presses at the Eastern Car Company's plant were being used for experimental purposes and when the first difficulties were overcome, shell forging commenced in earnest at that plant.

There were two presses, one 500 ton and one 250 ton, R. D. Wood Vertical Hydraulic Presses, and one Laidlaw Dunn Gordon Comp. Engine driven hydraulic pump that could more than supply the presses and other equipment when working on ordinary car work, but when forging shells it was quickly found that the pump was not going to fill the bill easily. The press operations were becoming quicker as the munition makers became more expert and a general improvement in the treatment of steel used for punches and dies enabled them to turn out more work without changing.

One morning the master mechanic came into the Power House and sized up the situation thus. "Mac, we've got to bolster this thing up some way. There are two new presses on the way here now."

"Oh, goodnight," I thought, "the accumulator is hitting the blocks now."

I told him I'd overhaul the water end Sunday. I did so and found the valves in good order. It was the same thing Monday. All the pump could do. At times when both presses operated together they would bring the accumulator to the bottom and the pressure would fall to zero—the pump going for all it was worth—when the press operator closed the operating valve the pressure built up instantly to 1500 lbs. per sq. in. with a shock that would almost carry the lines away.

"Well," I thought, "if the pump can stand up to this kind of work it is better than any machine I ever saw," and at short notice another pump was out of the question.

The speed of the pump was 55R.P.M., this speed being determined by the flyball governor, "belt driven." I took up the matter of increasing the speed to 72 R.P.M. with the master mechanic next day. After arguing that the whole system would be wrecked before a new pump could be had, I finally got his consent and had a new pulley made and put on. Well, we got 72 R.P.M. all right.

Hitting A Snag

This is what happened. Everything started away O.K. and the engine was doing nicely. I felt pretty good over the stunt just pulled off, but when I happened to look around the accumulator was up at the blow holes on the rod and the engine going full speed. Before I got to the throttle the accumulator was bounding up and down at the top of the rod like a trip hammer, the pressure gauge showing 4000 llbs. every surge of the accumulator and back to zero. Out at the press the operator let the operating lever go and beat it for his life, leaving the shell press thrashing up and down until it was almost wrecked before I had the pump shut off. Half a dozen men came running in to see what happened, some of them heard on the way in that the boilers exploded and others thought it was a German bomb explosion. Anyway when we saw who they were I postponed explanations and solemnly assured them that the whole thing was caused by an accumulation of air in the top of the accumulator. That it was O. K. now. They went away marvelling at our ability to handle such a serious situation in so short a time and passed the word that "there was air in the accumulator, but Mac's got it straightened out."

It was early and the Master Mechanic had not arrived so I put a man at the throttle for the time being. When the Master Mechanic came in I told him what happened. Now he was a man that when you were in trouble was right with you to the limit until it was over and lecture afterwards. What did happen was that the inertia of the heavy flywheels at 72 R. P. M. with what steam was between the chrometer valve and the engine and what was in the receiver carried the engine forward after the accumulator had closed the chrometer valve until it had uncovered the ports again by overtravelling, thus admitting fresh steam and forcing the accumulator up to the blow holes in the rod at a pretty good clip. The inertia of the weight carrying the accumulator past a number of the holes thus relieving all the pressure on the line for an instant. The weight of 150 tons was, you might say, suspended in mid air, then falling back onto the column of water compressed the air in the top of the cylinder and at the same time compressed all the spring shock absorbers on the line. The combined reaction of the shock absorbers, the expansion of the air at the top of the cylinders and the discharge from the pump driving the accumulator up again above the blow holes. This was repeated with the regularlity of steam hammer until the throttle was shut off.

How It Was Remedied

Before another day passed we devised a slotted link that would allow the inertia of the engine to be spent before the accumulator pulled the valve across the seat, the slot being made long enough as may be seen from the sketch. The cable was made fast to a turn buckle so that the length could be adjusted as the cable stretched. When the valve is open the pressure on both sides is balanced and a spring keeps the lever up to the forward end of the slot. As soon as the ports in the valve are closed the pressure is all on the back or inlet side and the unbalancing causes the valve to remain stationary while the

spring allows the link to be carried forward. When the accumulator comes down, the backweight opens the chrometer valve and allows the pump to start up.

Part of the unbalanced pressure on the valve is carried on an adjusting stud so that the valve won't bear too heavy on the seat. This stud used to make contact with the valve stem and the constant motion used to wear it quite rapidly as there was not much chance to oil it. This meant that with the accumulator at the top of the rod and the presses standing at the valve stem shortened by contraction, due to steam being shut off, the engine would allow the valve to seat so firmly that a 60 lb. weight would not open it when the presses started again. It was usual to watch it at such times and give the weight a kick away, but it sometimes happened that the accumulator would be down before it would be noticed. One day my assistant noticed that the valve was stuck. He ran over and grabbed the rope at X (see sketch) and gave a pull, with the result that his hand was drawn into the sheave and he lost three fingers.

Then I cudgelled my brain for an idea. Two electricians were doing a repair job shortly afterwards and were making a fibre plug. As I watched them I decided where a fibre plug would be a good thing and as far as I know that fibre plug is there now. It is inserted between the adjusting stud and the valve stem. Now the new presses were installed and we were up against it again, for capacity. We had been using one accumulator and keeping the other all ready packed for a standby, during those strenuous days a set of packing would last about 72 hours as a rule (and it was some job to pack the rod, especially if the accumulator did not set level after letting it down). So now we had to put both in the line as this gave increased accumulator capacity and so sensitive were they that if the packing was tighter on one than the other we had to balance them by throwing scrap iron from one to the other.

Emergency Tools

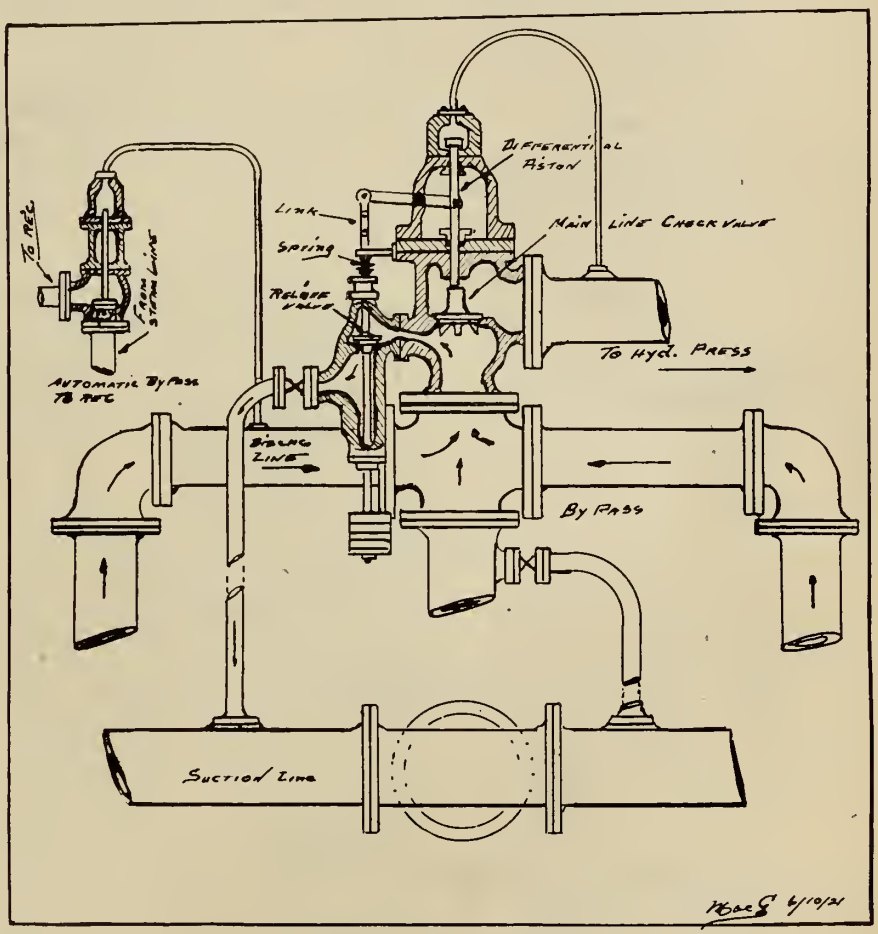
About this time the valves in the water end were getting bad. Formerly we used to reseat and regrind the valves between car orders, having anywhere from two weeks to two months in which to do the work. We used to do the work by hand, grinding the valve into a seat, but now all the time we could expect was from 11 o'clock Saturday night to 6 a.m. Sunday morning and we had 42 valves and seats in bad condition and no spares. So one week end we had a draftsman make a drawing of a valve and seat and by the next Saturday we had a cutter made that could be used with an air motor and a socket for grinding by motor. We commenced at 6 A. M. Sunday morning and at 9.30 P. M. we had 42 valves fitted and all the covers on but the last one. A test that night showed a displacement efficiency of 96½%, which was good when you consider that we rushed the job and that the pressure pumped against on the test was 1500 lbs. per sq. in. See sketch for tools used with air motor for reseating and regrinding. For regrinding we used a light air motor.

Once when two of the studs in the plunger stuffing box broke causing the gland to be broken in three pieces and tearing the plunger, so badly that it was ruined, we simply dropped a blank gasket into a flanged connection on the suction of the crippled plunger, cleared the broken gland and cut the damaged neck ring clear and started up with two plungers working again, after a shut down of 17 minutes. Of course the press foreman logged two hours delay against hydraulic pump, but he didn't know that the general manager happened to be on the scene as well as the master mechanic. The time was about 2.30 P. M. If it had been 2.30 A. M. Mr. Foreman would have got away with it. However five minutes delay at the power house might easily under some circumstances cause two hours delay at the forging presses unless there was a warning given before closing down. Of course when an accident happened there was no chance for a warning.

In those days the general managers worked side by side with the men during the early stages when shell forging was yet in a somewhat experimental stage—everybody worked (but the engineer). We had strict orders to challenge anybody except a company official found inside of the premises and to ask to see their pass. If they had none or refused to produce one, "Call a Cop."

The execution of this order called for a certain amount of judgment and diplomacy, since it was difficult to know who was an official and who was not, as officials did not always go about with white collars, shaven chins and manicured finger nails, and instead of being in bed the night before they may have been in the mill all night trying out some new punch or die or furnace and would look somewhat disreputable to a stranger. So we got in wrong once in a while.

An amusing incident occurred about this time. One day I was busy (A strange thing for the engineer to be busy), when I looked up from my work. I saw two men standing in the middle of the floor taking stock and discussing the equipment. One of them did not look too bad but the other was to say the least, disreputable looking, but I could see at the first glance that he was no fool. It was more than mere curiosity that brought him in. There was something uncommon about him, "looked like a dangerous cuss." That was the way we sized him up. (If he should read this he will smile.) They were duly challenged and could produce no passes and



Hydraulic regulator for by-pass.

seemed rather unwilling to give satisfactory answers. After explaining that Col. Cantley's orders were that visitors should have a pass or leave the premises they were not inclined to go I started for the telephone when they explained who they were and produced satisfactory evidence. I found to my utter astonishment that the disreputable looking fellow was the son of Col. Cantley and was assistant to his father, as well as Superintendent of shell forging in the steel works and one of the smartest mechanics in Eastern Canada.

I found out a little later that same day that he had been on the job for 36 hours without sleep or rest and had dropped into our plant to compare notes. His father was President and General Manager of both concerns.

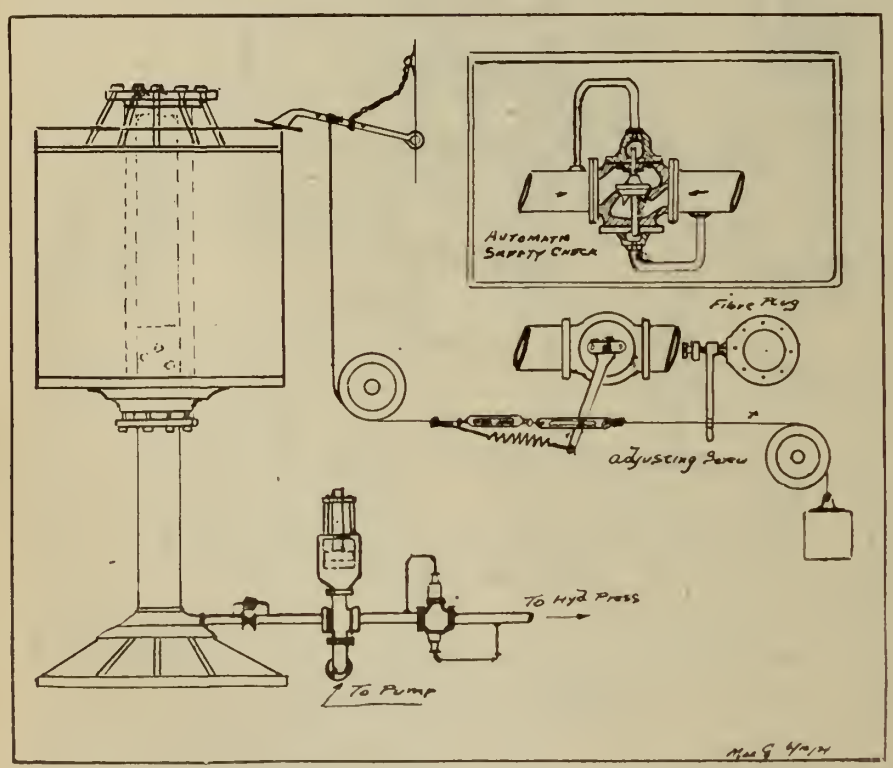
A Serious Accident

It was Sunday evening at 5.30 P. M. that one of the most serious accidents occurred. During the period I speak of shell forging activities were at their height. We were supplying two 250 ton C. P. R. Hyd. presses, one 250 ton and one 500 ton R. D. Wood presses with one 400 gal. pump and using two accumulators. There was nothing to spare, we were short of power at best so everything had to be in the best of order to carry on through the week. Sunday was repair day. It was the custom after the pump was packed and the accumulators packed and all the leaks on the system were attended to, press operating valve leathers renewed and pump valves overhauled, to test the system. After the test the accumulator was pumped to the top of the rod, the pump was stopped and if the system as a whole was tight the accumulator stayed up, if there were leaks the accumulator would creep down, then there would be a hunt for the leak, with a view to repairs. This day we found everything O. K. The accumulator was at the top and staying there, the men beat it for home. I filled my pipe to have a comfortable smoke while waiting for the night engineer, feeling that we were in luck to get through so early. I was facing the accumulator when I saw it start for the bottom like a falling stone. There was a crunch of timbers and a crash of bursting metal when it struck the bottom. (A weight of 150 tons falling 18 feet will do some damage to itself when it strikes solid bottom).

The accumulator when resting sits on oak timbers built up from the foundation 10" x 10" oak laid on top of each other to a height of 5 ft. The weight went through the oak as if was match wood. The rod was driven out through the cap, the pipe lines cut off and gland and stuffing box smashed, in fact the whole thing was wrecked.

What happened was that a length of double ex-heavy hyd. pipe in the pipe tunnel split for its entire length, releasing the water. The Master Mechanic rushed out a gang of pipe fitters, had the lines repaired and we were operating at 12 P. M. that night with one accumulator. It was a costly repair job and if we had had both accumulators up at the time of the accident we would have lost them.

The Master Mechanic came in one day and says "Mac. what's to prevent that happening again?" "Nothing" says I. But that set me thinking. By night I had an idea. We both got at it with the result that we patented the safety check valve shown here. Moreover we developed the idea until we succeeded in patenting a triple duty valve (not shown).



Throttling arrangement on hydraulic pump.

The valve is kept in open position by having an area in contact with the line side greatly in excess of that on the accumulator side to prevent slamming, should the pressure on the pump or accumulator side fall off greatly such as would be caused by a broken line the accumulator pressure will force the check valve to its seat. So that there won't be too much of a shock when the check seats there are holes drilled in the valve to allow a small amount of water to pass through and let the accumulator down slowly.

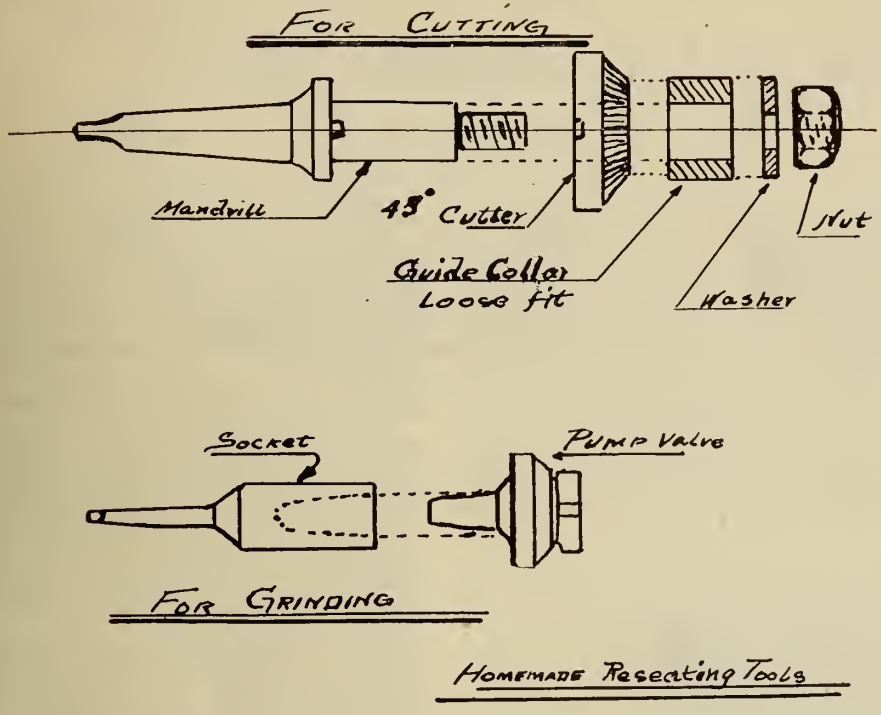
The relief on this pump is very interesting and requires very little explanation. When starting up, the bypass is opened up but when the pump is in operation on ordinary classes of work there will be many times when the presses or hyd. riveters are not using water. The pump will be stopped and the accumulator weight will maintain the line pressure at 1500 or whatever normal pressure may be. This means that if there is no relief valve the pump must start against line pressure (This the pump won't do if the Engine is stopped on a weak point, say with the H. P. steam adm. valve hooked off or when just over the centre without the aid of a steam bypass. This condition is taken care of by an automatic bypass described later). So the idea of a relief valve is to allow the pump to keep in constant motion at a slow rate of speed without coming to a dead stop.

Operation of the relief valve is as follows. When the pump is checked by the closing of the chrometer valve the main line check valve seats. The line pressure acting on the top of the differential piston forces it down following the check valve. This movement opens the relief valve. The pump will then pump through the relief to the suction.

When the pump speeds up for work all the volume of water pumped cannot pass through the relief valve but forces the main check from its seat and forcing the differential piston to its highest position, allowing the relief valve to be closed by the weight. Then all the water goes through the main check to the lines.

Automatic Steam Bypass to Receiver.

When the pumping engine is for any reason standing there is no water pressure on the pump side of the main line check. Should the steam adm. valve on the H. P. be unhooked the chrometer valve would not admit steam to the receiver and the low pressure cylinders so a bypass was connected into the receiver, being opened when the chrometer valve opened by the steam acting underneath the disc. and when the pump started up the bypass valve was closed by hydraulic pressure from the pump side of the main check. Thus the pump would start from any position, being automat-



Home made tools used for reseating and regrinding hydraulic pump valves. With the above outfit and two spare cutters, 42 valves and seats were cut and ground in 12 hours actual working time. A test showed the water end efficiency to be 96½%. Slight gland leakage not measured.

ically bypassed both steam and water ends would normally be kept moving slowly when the presses were idle, preventing an accumulation of condensation and excessive strains set up by expansion and contraction.

Besides the hydraulic system we had the air compressors, boilers, stokers, turbines and generators to look after, any one of which was necessary to shell making.

In this connection I might mention a stunt pulled off by the electrical engineer.One evening, as we had only one exciter available at the time just as if the devil himself was conspiring to throw us down, the exciter went on the blink.

The electrical engineer was called in for consultation. It looked bad, for a time. There was an old D. C. line coming in from the steel works that had been there from construction days. The voltage at the steel plant was 220, but owing to the line being small it would not serve 25% of the D. C. required at the car plant and anyhow we had to have A. C. to operate at all. After locking himself up in the office for ten minutes he had a plan and inside of half an hour we were operating. This is what he did.

The line drop was considerably over the old D. C. line (this was favorable) so he disconnected the A. C. field resistance from the idle generator and put two A. C. field resistance in series on the one generator, put a man at the A. C. rheostat to regulate the voltage as required. The result was that we were able to operate (with a somewhat fluctuating voltage) until the necessary repairs were made.

INVESTIGATION OF COAL GAS

As the result of a study of the formation of tar emulsions in water-gas sets, made under a co-operative agreement of the United States Bureau of Mines, the University of Illinois, and the Illinois Geological Survey, at Urbana, Illinois. it has been proved that tar emulsions could be largely prevented by proper manipulation. A method was developed for determining rapidly the percentage of water in tar emulsions. A full report of the results of these experiments and the methods of preventing emulsions in operation is being published by the University of Illinois Experiment Station at Urbana, Ill.

The results of a series of experiments conducted for the Bureau of Mines by W. W. Odell, illuminating gas engineer, at Davenport, Iowa, indicate that mixtures of some mid-western coals and coke give satisfactory service as fuel in water-gas sets in substitution for the high-grade eastern coke generally used in that section. By the use of such mixtures a considerable saving in cost may be effected without introducing any serious difficulties in the process of manufacture. A report on these tests will be published as a technical paper of the Bureau of Mines.

On the transfer of Mr. Odell to other duties, the study of the use of central district fuels in water-gas sets was continued for the Bureau of Mines by W. A. Dunkley. Mr. Dunkley conducted experiments in the 11-foot water-gas sets of the Coal Products Manufacturing Company, at Joliet, Illinois, with coal from the No. 2 bed mined at Murphysboro, Illinois. Many difficulties encountered in using coal have been gradually overcome. A report of these experiments is in preparation. Mr. Dunkley devised a test for comparing the activities of iron oxide for gas purification. This test has been tried out by seven gas laboratories, and substantial agreement in results with six standard samples of oxide has been obtained.

A series of tests on the effects of using steam in steaming horizontal gas retorts has been made by the Bureau of Mines, in co-operation with the Illinois State Geological Survey, at Mendota, Illinois, with coals from the Elkhorn district of Kentucky and from Franklin County, Ill. With a coking time of 6 to 8 hours, approximately 5 per cent. more heating value in the gas per pound of coal was obtained.

At the Pittsburgh, Pa., experiment station of the Bureau of Mines, investigations relating to the purification of city gas are being continued in co-operation with the purification committee of the American Gas Association. A. C. Fieldner, chairman of the committee, and Superintendent of the Pittsburgh Experiment Station, is in general charge of the work. At this station, A. R. Powell and G. S. Scott are working on the development of improved methods for determining the efficiency of iron oxides for gas purification. A bibliography on gas purification is in preparation.

At the Pittsburgh Experiment Station, co-operative work has been conducted with the Bureau of Standards relative to the quantity of carbon monoxide produced when natural gas is burned in house-heating appliances under different burner adjustments. Carbon monoxide is formed in appreciable quantities if a burner is not carefully regulated as to the height of the pan above the burner, the quantity of primary air added, and the design of the burner

An investigation has been conducted at Pittsburgh by the Bureau of Mines to determine the quantity of nitrogen produced when gases are analyzed by the slow-combustion and the explosion methods. The tests indicate that negligible amounts are produced by the slow-combustion method when properly conducted and none by the explosion method when air is used as the oxygen supply, although appreciable quantities are formed when mixtures of air and oxygen are used.

CATALOGUES

Chas. Cory & Sons, New York, have taken over the manufacturing and selling of the Royer Flow Indicators from the A. H. Sloan Company Inc. of Detroit, Michigan. The catalogue Bulletin 5-B describes a number of types of these indicating flow meters, designed for a wide variety of service. The Pitot tube is the basis of the design of all these meters, the construction being modified to suit the different services.

The Value of Intercooling Air

By C. K. Bennett*

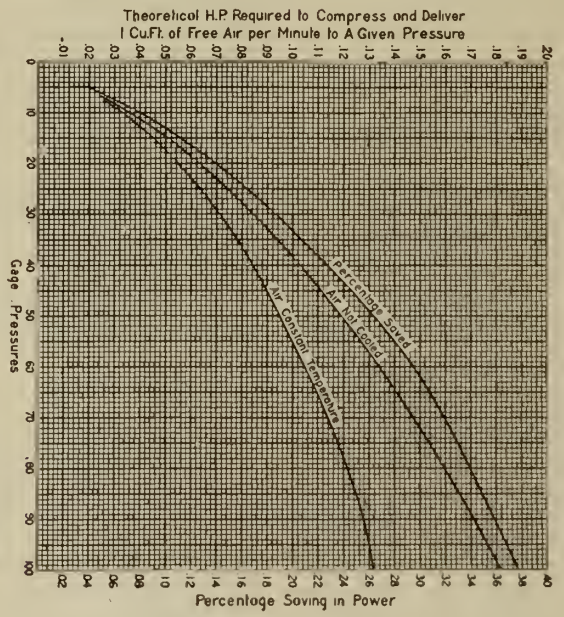
COMMERCIAL air compressors are water cooled either by injecting water into the compressor cylinders, water-jacketing the cylinders, or by compressing the air in two or more stages and cooling the air between cylinders by means of water-jacket vessels known as intercoolers. Two of these methods are generally used together on the same compressor.

Water injection has never been extensively adopted in this country inasmuch as its use is limited by several disadvantages. The water feeding devices demand constant attention. The air becomes saturated with water vapor and this moisture increases cylinder and piston wear, and later frequently gives trouble by freezing when air is expanded in doing work.

Jacketing the cylinders is simpler than either of the other cooling methods. However, it is less efficient. Since the period of compression is short and therefore only a small percentage of the total volume of compressed air, delivered at each stroke, can come into contact with the water cooled cylinder, the cooling effect is small.

For these reasons, modern practice is to compress the air in stages, and to cool it between stages by means of efficient inter-coolers. Thus the increase in pressure from atmospheric to desired delivery pressure is divided among two or more cylinders, and the temperature rise per cylinder is limited. The air is first compressed to a moderate pressure in one cylinder and thereupon passed to an intercooler wherein its temperature is considerably lowered and the volume of the air correspondingly reduced. The cooled air is then forced to the next cylinder and so on, until the final delivery pressure is attained in the last cylinder, whereupon the air is passed to an after-cooler and thence to the receiver or storage tank. The intercoolers between the cylinders and the aftercooler after the high pressure cylinder remove most of the heat of compression.

The most important advantage of compressing the air in stages and intercooling the air between cylinders is that power is saved—particularly in instances where the compressed air is passed to a receiver in which it remains for some time before being put to use, or where the air is transmitted a considerable distance from the compressor.



Theoretical H.P. Required to Compress and Deliver
1 Cu.Ft. of Free Air per Minute to A Given Pressure
Gage Pressures
Percentage Saved
Air Not Cooled
Air Cooled to Constant Temperature
Percentage Saving in Power

Fig. 1.—Theoretical power to compress air.

Power Saved By Cooling

Fig. 1 shows the theoretical H. P. required to compress and deliver 1 cu. ft. of free air per min. to a given pressure; first, when the temperature is maintained constant during compression, second, when the air is compressed without cooling. The first process is known as an isothermal compression and is approximated by compressing in stages and intercooling; the second is an adiabatic compression, and the difference in the power requirements for the two processes is the theoretical saving in power that under ideal conditions may be approximated by means of multi-stage compression and intercooling. No allowance is made in Fig. 1 for friction or other losses.

Kent mentions that in cards taken from the 2,000 H.P. two stage air compressor at the Quai De La Gare Plant of the Paris compressed air central station company, the saving realized by means of multi-stage compression and intercooling is 85 per cent. of the theoretical amount. Of this 77 per cent. is mainly due to intercooling the air between the two compression stages.

Another advantage of intercooling compressed air is that most of the water vapor in the air is precipitated in the coolers and for this reason trouble by freezing is avoided. This is of value, especially when the air is subsequently to be used in air agitators in ice plants, stone drills, riveting machines, paint guns, etc. As the air expands in doing work in the pneumatic machine, it must absorb heat; and since the process takes place rapidly or adiabatically, most of the heat is supplied by the air itself. If the air contains any moisture, this vapor will be condensed during the air expansion and the condensation will either damage the pneumatic machine, or cause other trouble as in varnish sprays where the water would be sprayed over the furniture surfaces causing bubbles and pitting. Further if moisture condenses and collects in air pipe lines, it causes water hammer, leaky joints, and loss of power by accumulating at low points and reducing the air passage.

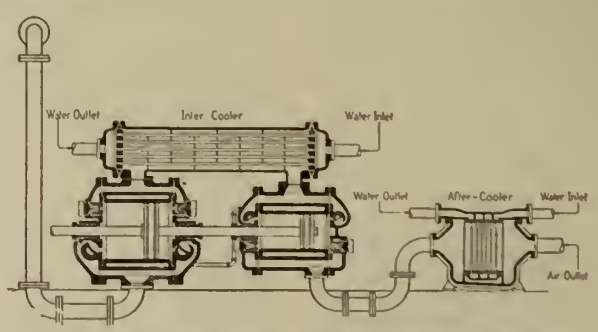


Fig. 2—Typical two stage air compressor with Inter and After Coolers.

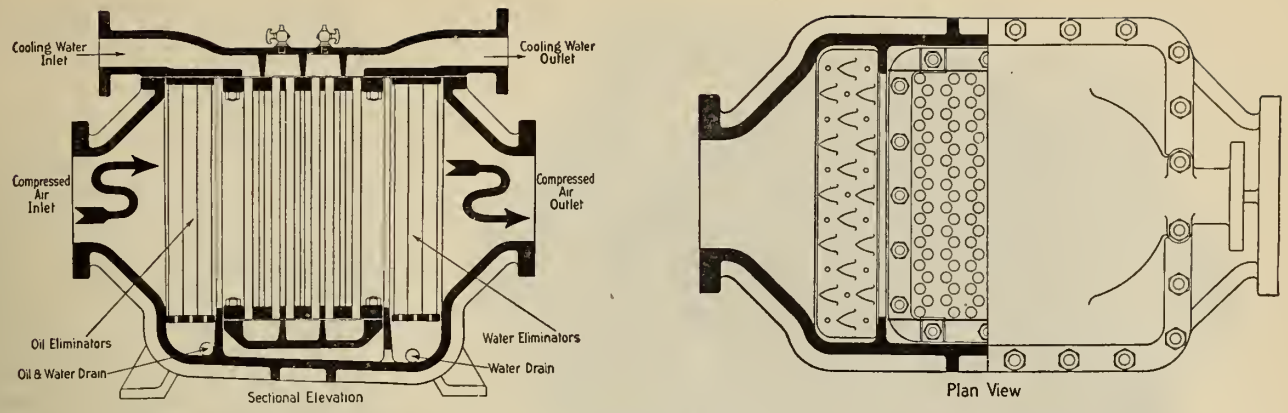

Fig. 3.—Sectional elevation of a typical intercooler, showing moisture and oil eliminators.

With single stage compression without intercooling, there is always danger of an explosion due to operating conditions. The air remaining in the clearance of the cylinder is at a high temperature, and is repeatedly recompressed, raising the temperature still further until a point is reached where the lubricating oil decomposes under the heat and vaporizes. The compressed air and vaporized oil form a mixture that may explode and cause serious damage.

Typical Two Stage Compressor

A typical two stage air compressor equipped with inter and after coolers is shown in Fig. 2. Air enters the low pressure cylinder through the open inlet valve, which, at the end of the suction stroke, closes. As the motion of the piston compresses the air filling the cylinder, the discharge valve opens automatically and allows the compressed air to pass to the intercooler where it is cooled and then discharged to the second cylinder or the subsequent stage. During its passage through the intercooler the air surrenders to the water practically all the heat of compression although some of this heat has already been absorbed by the water in the compressor water jacket. After the air leaves the last stage, it is usually conducted to an after-cooler, where the heat generated in the final stage of compression is removed in exactly the same manner as in the intercooler. The cooled high pressure air is then passed to the receiver where it is stored until drawn off for use as required.

A sectional elevation of a typical intercooler is shown in Fig. 3 and an outside view in Fig. 4. The air is carried around the outside of the tubes, and the cooling water through the tubes. As it is a simple matter to clean the inside of the tubes, very dirty water can be used. The current of air drawn across the tubes is continually divided or sliced into thin sheets or films, due to the close tube arrangement. Sluggish air flow or eddy currents are avoided. The air is brought into intimate contact with the tubes and a rapid and efficient absorption of the heat is effected. The use of straight tubes and the ease with which the cover plates can be removed contribute to rapidity and readiness in cleaning the cooler of scale deposited from the water. Any tube can be plugged or replaced without disturbing the others. Notwithstanding the small dimensions of the apparatus, the resistance to flow is low, and large quantities of air can therefore be handled with small frictional losses. Both oil and water eliminators are provided—thus practically all of the entrained moisture and oil is removed from the air. The importance of this has already been considered.

Fig. 5 is of interest inasmuch as it gives the heat transferred in B.t.u. per hr. per sq. ft. of cooling surface for 1°F. mean temperature difference between the air and water corresponding to different air and water velocities. The density of the air passing through the cooler generally varies from 0.6 to 0.025 lbs. per cu. ft. Thus, for an air speed of 50ft. per sec., the heat transfer rate from curve is about 48. This value however, must be corrected for the velocity of the water. Assuming the latter to be 1 ft. per sec., the correction factor from the curve is 1.4. Therefore 48 divided by 1.4—about 34, or the corrected heat transfer rate for a water velocity of 1 ft. per sec., an air velocity of 50 ft. per sec., when the density of the air is 0.2 lbs per cu. ft.

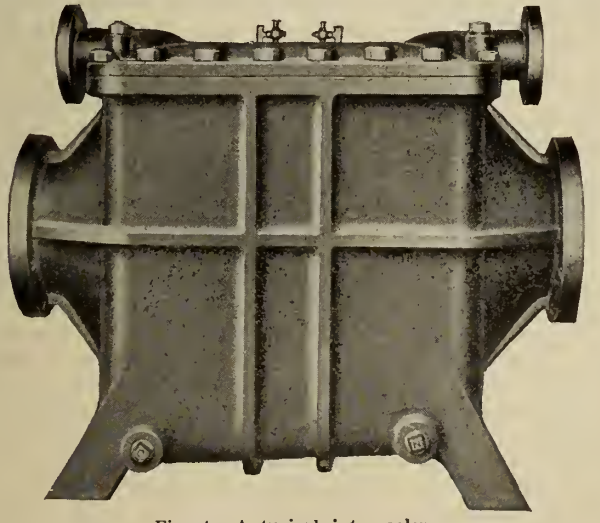

Fig. 4.—A typical intercooler.

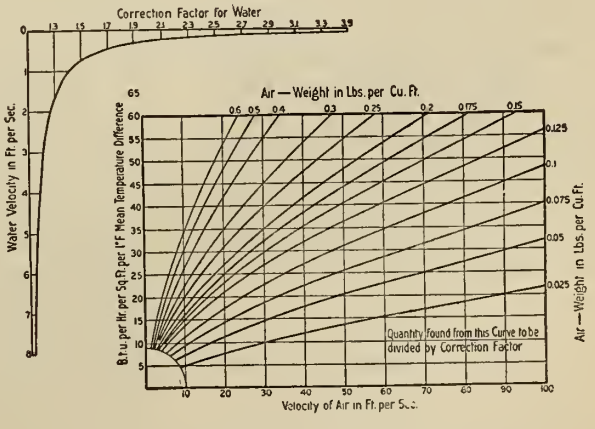

Correction Factor for Water

Quantity Found from this Curve to be divided by Correction Factor
Velocity of Air in Ft. per Sec.

Fig. 5.—Heat transmission curve for an intercooler.

Frequently the atmospheric air around power plants contains large quantities of dust and dirt and must be filtered before it is drawn into the air compressor. A typical dry air filter is shown in Fig. 6, and consists of a box open on two opposite sides for the admission and discharge of the air. Inside the filter are a number of vertical frames, the openings of which are so dimensioned that any given velocity of air flow can be obtained. The frame is built in a rectangular shape to which are fastened many fine parallel cotton threads forming the openings of the filter. The open sides of the filter box are protected by wire screens.

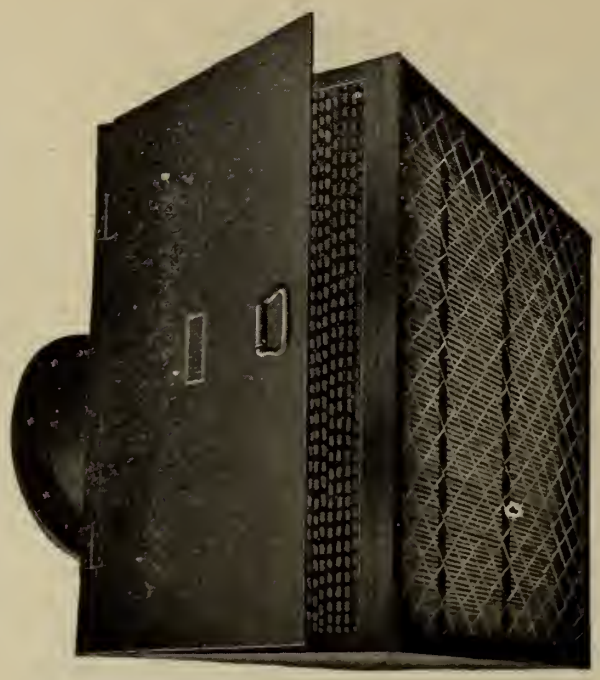

Fig. 6.—A typical dry air filter

Unless coal dust and dirt are removed from the air, they will enter the compressor cylinder, adhere to the oil film, and the combined dirt and oil will under the influence of the high temperature be baked into a gritty mass and deposited on the valves, etc. Under these conditions the machine must be shut down frequently and the valves cleaned, otherwise there is danger of an explosion.

As many filter boxes as required are usually coupled together. The system occupies relatively small space and is generally arranged in a basement underneath the compressor or outside of the power house as conditions may warrant. The filter frames can be cleaned without interfering with the operation of the system, simply by opening the door and removing one frame at a time.

INVESTIGATING COKING COALS

The obtaining of a good grade of coke from coals which seemed devoid of any coking property has been accomplished by investigators at the University of Illinois, Urbana, Ill., working in co-operation with the United States Bureau of Mines, by the employment of a specially devised low temperature coking process. As a result of the process, valuable by-products, in the way of ammonia, gas and tar, are derived.

The experiments were undertaken in connection with an investigation by the Bureau of Mines of the smoke problem at Salt Lake City, Utah. It was found that coke was regularly obtained from only a few coals tributary to the Salt Lake City district, and, if the use of coke, a smokeless fuel, was to be increased in that city, it would be necessary to demonstrate the possibilities of coking coals not regularly used for that purpose. Six coals from various Utah districts were tested.

Although, so far as present standards of coking indications are concerned, the coals tested seemed quite non-coking, treatment by the methods devised by Prof. S. W. Parr of the University of Illinois resulted in a yield of good coke amounting approximately 60 per cent of the coal employed. The coke is dense and of good texture, and seems adapted to use as a domestic fuel and for metallurgical purposes. In some respects the coke seems superior to anthracite for use in domestic furnaces. Slightly more than 20 pounds of ammonium sulphate, valuable as a fertilizer, were recovered per ton of coal coked. The gas recovered as a by-product is especially suitable for utilization in city mains. The tar oils obtained should lend themselves readily to cracking processes, thereby furnishing a product suitable for motor-fuel purposes, and may also prove a source of creosote oil and other wood preserving materials. These tar oils, on account of their marked drying properties, may also be available for paint and varnish manufacture. Other uses suggest themselves, such as direct combustion in engines of the Diesel type, as fuel for steam generation, as a source of heat for metallurgical purposes, the carburetting of water gas, and as the source of pitch as a binder for the briquetting of breeze, lignite fuels, etc.

The results of the investigation are of two-fold importance, indicating the possibility of coking many coals not generally considered to have coking qualities, and also constituting a factor in the solution of the smoke problem in communities not favorably situated for the obtaining of smokeless fuel.

DON'T FORCE A BELT

Many millwrights make the mistake of thinking that it is perfectly proper to force a belt to stay on its pulley by any means whatever. They seem to think that as long as the belt "runs" it is all right, and is doing as much as should be expected of it.

For instance, one millwright "took a piece of old three-inch rubber belt, pulled off one ply, wrapped it twice around the centre of a wooden pulley and nailed it solidly to the pulley," and then he goes on and says, "The belt immediately took its place on the centre of the pulley and stayed there."

It is true that nailing a ridge of any kind of belting on a wooden pulley to increase the crown will cause the belt to move over and run on the intensified crown, even though the alignment of the pulleys may be poor.

However, such a condition is hard on the belt, and if the millwright would give that side of the question some thought he would see that if the belt has much work to do it cannot endure.

Let us say that the width of the belt is 6 inches, and that the width of the ridge nailed on the pulley is only 3 inches. Six inches minus 3 inches equals 3 inches, which means that about 3 inches of the belt (1½ inches on each side of the centre) is not in contact with the driving pulley or driven pulley at all or is in poor contact. A very intense pressure between the belt and the pulley occur over the 3 inches of width of the ridge. In other words, 3 inches of width of the belt is compelled to do what 6 inches was intended to do.

Furthermore, with the rough face of the ridge rubbing against the equally rough face of the belt, and with the pull per square inch and the pressure per square inch doubled, it is evident that the wear on the 3-inch ridge is going to be greater than it would be on a smooth iron or smooth wooden pulley. It is quite possible that the slip is greater with the 3-inch strip than without the strip. At least the creep is as great one way as the other. From every angle, therefore, it is obvious that nailing a ridge around pulleys to increase crown is poor engineering.

It is far better to carefully align the pulleys and shafting so that the belt will run exactly as was intended by the designers of the pulleys. By using the low crown, the entire belt surface comes in contact with the pulley, both the load and the wear are evenly distributed.

In fact, pulley coverings should not be used at all. It has been proved time and again that the natural smooth face of a metal, wooden or other pulley is far superior to any roughened face. Rough faces are too hard on the belt.

A TWIN JET CONDENSER FOR A 20,000 KW. TURBINE

Herewith is illustrated the latest large jet condenser unit manufactured by t Wheeler Condenser & Engineering Co., Carteret, N. J., which is of special interest on account of its size and the operation of auxiliaries. It was built to serve a 20,000 KW. General Electric turbine at the Hauto, Pa., plant of the Pennsylvania Power and Light Co. Designed for 28 in. vacuum with 75 deg. injection water, it will handle a total of 25 000 g. p. m., or 12,500 g. p. m. for each removal pump.

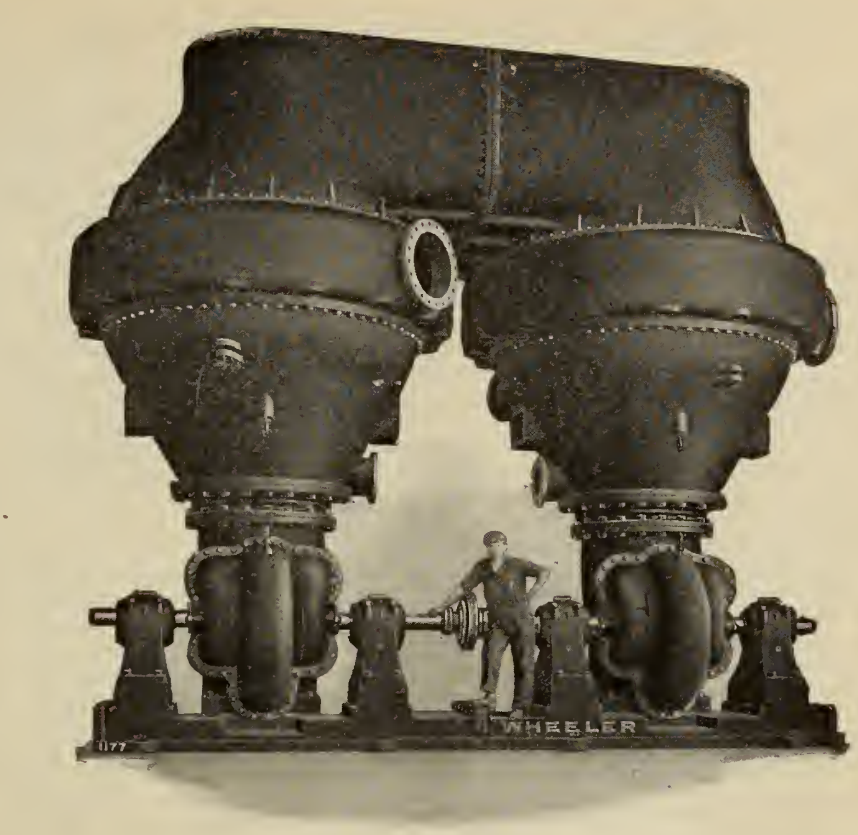
Twin jet condensers are frequently furnished for serving large units because they have greater flexibility, are easier to handle, and reduce the headroom. Each condenser body, as shown, is mounted over a separate removal pump, and will also provide with separate air pumps, so in times of light load or with cold injection water, only one-half of the unit need be operated, resulting in a saving of 50 per cent of the normal power. When in full operation, the water levels in the two bodies are equalized by means of a connecting pipe, flanges for which are the two lower ones shown on the condenser bodies opposite each other.

Both a geared turbine and motor are furnished to drive the removal pumps of this unit—each being large enough to drive both pumps alone—so that the load can be divided as required to maintain the heat balance of the plant by producing more or less exhaust steam, as can be utilized economically for heating feed water. These are not shown in the photograph, as they were sent direct to the plant, and could not be assembled in the shop where the photograph was taken. A feature of the pump drive is a magnetic clutch, which unites the shafts between the inside shaft bearings. It permits either pump to be driven independently of the other, without interfering with continuous operation, when only half of the condenser is to be operated.

As will be noted from the photograph, an expansion joint is provided between each condenser body and its removal pump. By this arrangement, the condenser body is suspended from the turbine nozzle, while the removal pump and driver are mounted upon a rigid foundation; the expansion joint in this way eliminates the large expansion joints usually placed between the turbine and the condenser.

Another point of interest is the vertically split casting of the horizontal double suction tail water pump serving each condenser. When it is necessary to inspect or repair the rotor or any of the wearing parts, it is simply a matter of removing the bolts, and uncoupling the rotor. Before this design was developed, considerable time and effort were required to get at and remove the rotor.

This huge condensing unit will be served by two large Wheeler steam jet air pumps of the combined surface intercondenser and heater type, and two turbo air pumps, each pump being large enough for one condenser. Boiler feed make-up is circulated to the intercondenser and heater of each steam jet air pump.



Large jet condenser for a 20,000 k.w. turbine.

MINING FATALITY RATE

According to reports received by the United States Bureau of Mines from the various state mine inspectors, 152 men were killed during September in and about the coal mines of the country, as compared with 197 killed in the corresponding month in 1920. The 1921 figures show a decrease of 45 fatalities, or about 23 per cent., from the record of the same month of last year. Based upon an estimated output of 42,229,000 short tons in September, 1921, the fatality rate is 3.60 per million tons produced. The corresponding rate for September last year was 3.66 and the production of coal was 53,810,000. The production of coal during September, 1921, represents a decrease of 22 per cent.

The average number of lives lost during September of each year from 1913 to 1920 has been 189. The production of coal has averaged 51,886,000 tons showing a fatality rate of 3.64 per million tons as representative of the month of September for the past eight years.

During the first nine months of the present year 1,455 have been killed by accidents at coal mines, against 1,686 killed during the corresponding months of 1920, a decrease of 231 fatalities, or 14 per cent. The output of coal for the same months was 362,800,000 short tons in 1921 and 473,100,000 tons in 1920, a decrease during the present year of 110,300,000 tons or 23 per cent. These figures represent a fatality rate of 4.01 per million tons mined in 1921 and 3.56 per million tons mined in 1920.

Of the total of 152 fatalities during September, 30 occurred at the bituminous coal mines in Pennsylvania, a decrease of 15 from September a year ago; 25 in West Virginia, a decrease of 6; 14 in Illinois, a reduction of 3; 6 in Kentucky, a reduction of 8; 5 in Ohio, a reduction of 13; 5 in Alabama, a reduction of 4; 3 in Indiana, a reduction of 12. At the anthracite mines in Pennsylvania, 41 men were killed, as against 20 during September of last year.

The Quigley Furnace Specialties Co., Inc., New York have disposed of their Pulverised Fuel Department to the Hardinge Company of the same city. The engineering department of the Quigley Company in connection with the pulverized fuel division has been taken over in its entirety, so that the Hardinge Company will be able to carry on the business without a break. This new arrangement leaves the Quigley Co. free to devote their efforts to the refractory specialty business, which has assumed proportions that call for their full attention.

It is understood that the electric power plant at Morinville, Alberta, owned by Mr. E. A. Brault, will shortly be changed from a gasoline engine to a steam engine prime mover.

Central Oiling Systems for Power Plants

The Treatment of Oil For Continuous Use—Correct Lubrication —Impurities—Precipitation — Filtration — Entrained Water — Action of Heat—Filtering Materials—Separation of Water—Oils Themselves Nearly Perfect

EVERY known device that will assist in producing the highest mechanical efficiency in power manufacturing apparatus is used in the modern power plant. Very prominent among changes in recent years is the item of scientific lubrication.

What is meant by scentific lubrication? It means: Choosing the correct lubricant for a particular class of service; distributing the oil to the bearings through an automatic oiling system that is positive and needs no personal attention; applying the oil in such a manner that the least possible energy will be consumed in internal bearing friction; practising the utmost elimination of waste by recovering every drop of the used oil after it has passed through the bearings, reclaiming it, and putting it back into the system.

Correct Lubrication

Stream feeding of the proper quality of oil to the engine bearings is recognized as being the ultimate in perfect lubrication, and is the limit beyond which friction cannot be reduced by lubrication. Correct lubrication requires that the thinnest possible film of the most friction-reducing fluid must possess sufficient cohesive property, that its film be unbroken and never permit the rubbing surfaces to come in contact, even in spots. It must not have a body any heavier than is just enough to maintain this film, for unnecessary energy will be lost in overcoming the internal friction of the fluid.

In order that the oil possessing the least amount of internal friction or viscosity can be used on a bearing and yet maintain the continuous lubrication film, it is necessary to put as much oil on bearing as it will take and introduce it in the journal at the point of least film pressure. This flood of oil insures an unbroken film of the most friction reducing fluid; carries away worn metal, which, if allowed to remain will cause unnecessary wear; keeps the bearing cool by absorbing what frictional heat there may be generated and gives to that bearing every condition that makes perfect lubrication possible.

The merits of stream feeding of oil for bearing lubrication are unquestionable. Although when one thinks of the enormous expense necessary to keep a stream of new oil running on all bearings in a plant, the cost of this kind of lubrication seems to be almost prohibitive; but the impossible expense of flood lubrication vanishes when a system may be installed for collecting this used oil and continuously circulating it from a large reservoir to the bearings and back to the reservoir again. There is no wear-out to good oil, if it is properly separated from the impurity which it has picked up during use. Good oil may be used indefinitely with positively no chemical change and only a very small decrease in volume due to slight evaporation. When an efficient filter is added to this oil circulation system, a combination is had that will deliver perfect lubrication to all bearings at a cost that is almost nothing.

Impurities

Used lubricating oil contains various kinds of impurities which it picks up during its travel through the engine bearings, drip pans, oil conductors, etc. These impurities must be entirely removed before the oil is fit for re-use. The character of this foreign matter differs with the kind of oil used, the class of service the oil is used in, bearing temperature, atmospheric conditions surrounding a plant, quality of water and kind of boiler compounds used. The objectionable impurity is composed of grit, graphite, grease, slimes, worn metal, paraffine, sludge and water, but for its clarification in a gravity filter it may be roughly classified as, first, those impurities heavier than oil, and second those impurities the same weight as, or lighter than oil.

Lubricating oil has been passed through sand, charcoal, sawdust, cotton waste, Fuller's earth, and even water as a means of separating from it all of those impurities which impair it as a lubricant, and make it unfit for reuse. The quality of the recovered oil generally has been pretty good after the use of these various filtering media. However, the requirements of a modern oil circulation system, in average size power plants, demand the continuous purifying of too much oil per hour for the use of a drip filter bed, of any porous material. Such a bed to be efficient and have enough capacity would have to be too large to be practical.

Oil filters of the latest design used in handling continuous flowing large capacities, resort to other methods than the use of a filter bed, composed of coarse materials. The efficiency of these new filters has been very high, for they have used the value of precipitation to its fullest extent. This precipitation action is combined with the use of a filtering medium of such material that it can present a large area of surface compactly in a small amount of space. Those impurities heavier than the oil are removed by the process of precipitation, and all impurities possessing the same weight as or lighter than oil, in which they are suspended, are removed by filtration. It is found by handling each of these two groups separately and by taking advantage of a very thorough process of precipitation, that in the filtering action, a finer medium may be used and a better quality of purified oil will be the result.

Precipitation

Precipitation can be the result of the action of some chemical reagent or the natural settling by gravity of any impurity heavier than oil. If the oil be permitted to stand at rest in a vessel during a long period of time, and be free from the slightest movement, all impurities held in suspension will seek a stratum in the oil depending entirely upon their relative weights. Impurities heavier than oil will rest on the bottom of the vessel, while lighter impurities will seek the surface and remain on the top of the oil. The best known example of this precipitation or separation by gravity is found in the paint bucket. The heavy coloring pigments will settle to the bottom of the bucket after separating from the vehicle, while the lighter thinning liquids rise to the top of the bucket. The thoroughness of this separation depends upon the length of time the paint is allowed to stand at rest.

Filtration

Filtration is another name for screening the oil through a fine mesh or porous substance capable of permitting the clean oil to pass through the small openings. Filtration of a liquid may be compared to the screening of a dry substance. Uniform, dry, granular substances are separated from the large undesirable sizes by passing the grains through a screen. A liquid is made free of the large undesirable matter by passing the liquid through a filter. The two processes are identical for the action of the screen and the filter are the same.

Filtration is a continuous method of removing impurities, in which method time is not as much of a factor in determining its most perfect performance as is the density of the filtering material. If the liquid be allowed to pass through some material having microscopically small openings, exactly uniform in size and shape, perfect filtration of the liquid would be the result. The highest commercial degree of perfection is reached when the clarified oil has been freed from all injurious impurities and its condition returned to such a state, that, for the duty it is to perform, the oil is as good as new. To make it any better would require an expenditure out of proportion to the gain of value in the oil.

A drop of lubricating oil is composed of thousands of minute globules or mo-

lecules of oil. In a pure oil that is highly refined, there is only a very small percentage of foreign matter between these molecules, and the molecules, are very close together. A poorly refined, or impure oil, contains a great deal of foreign matter between the molecules, so that a drop of this substance possesses only a few scattered molecules of real oil, and consequently is a poor lubricant.

Entrained Water

All used engine and turbine oils, due to contact with steam, collect more or less water, which must be extracted during filtering process. Free water, or water that is in no way mixed with the oil, will settle rapidly by gravity; that is, the water is so much heavier than the oil that it falls to the bottom of the containing vessel, while the oil rises to the surface of the water. The separation is complete and almost instantaneous. Where live steam comes in contact with the oil, however, it is possible for the steam to become so entrapped in the body of the oil that it will not condense as water, but will remain suspended in the oil as vapor until a point of saturation is reached, above which the steam will collect and separate as free water. This entrained water that has been trapped between the minute globules of oil will not settle out by gravity under ordinary conditions—no matter how long the oil may remain in a state of rest. It must be remembered that every molecule of foreign matter contained in the oil, including entrained water, is so covered with a coat of oil that the oil prevents the particle from separating.

Action of Heat

When oil is heated to a temperature of approximately 180 deg. F., the cohesive force between the oil globules is temporarily weakened, sufficiently to spread the globules apart and to release the foreign impurities which are entrapped between them. This cohesive force or viscosity, possessed by the oil, is a necessary lubricating property. Nevertheless, this physical property must be temporarily changed during the process of purification. Increasing the temperature of the oil reduces this viscosity, and at a temperature near 180 deg. F. depending upon the quality of the oil, the oil loses its cohesive force and becomes "thin" as water. While at this temperature, if it be allowed to remain approximately in a state of rest for a comparatively short time, all the water and other impurities heavier than the oil will precipitate. It is upon this principle that the separator in the latest purifiers is based. So efficient is its action that only a very small per cent of the impurity is left to be removed by the filtering medium.

Filtering Materials

Of all the various kinds of filtering material used in a continuous flow oil filter for removing those impurities that will not settle by gravity, nothing has been found that can equal, in every respect, a closely woven heavy grade of cotton cloth. It is a material that is cheap and will not dissolve or possess fine particles that will work into the oil and find their way to the bearings to clog and injure them. The material provides uniform microscopically small voids or openings for the passage of oil so that the straining action will be uniformly complete. This material is such that an extended area of straining surface can be provided for the oil. It is the area of surface and not the depth of medium that does the straining. In passing a dry material through a number of screens of the same mesh, it is the first screen that does all of the separation. Any size that will pass through the first screen will pass through each of the succeeding screens having the same size openings, no matter how numerous these screens may be. This cotton cloth is of such nature that it adapts itself to the best approved mechanical arrangements, and when firm and strong will withstand many thorough cleanings before being thrown away.

The use of a low pressure head of 4 to 6 in. to force the flow of clean oil through the cloth is very desirable. For the best results, this pressure should be uniform over every square inch of the area of cloth and remain constant during its entire period of use.

When it is necessary gradually to build up a high pressure head upon the filtering medium as the sediment accumulates, a stream of dirt as well as oil will be forced through the cloth which would otherwise be completely obstructed. The only duty of a filtering medium is to separate impurities from the oil; but, if, for additional capacity, under either normal or overloaded conditions, this action has to be sacrificed to any degree, the purpose of the filter is lost.

Separation of Water

The worst impurity to separate from oil is entrained water, which is held in suspension as an emulsion. Free water separates readily, but entrained water will only settle out when the surrounding conditions are ideal. Heat at a temperature around 180 deg. F., state of absolute rest in the body of the oil, and the action of gravity during a long period of time, are all necessary conditions which will aid in separating an emulsion, provided its resistance is not too high. While these conditions can be approximated in a continuous flow filter, it is only in a filter that will handle oil in batches, that their value may be used to their fullest extent. Better clarification of oil can always be had in a batch filter, than one built for continuous flow. The element of time which enters in their action is a most important factor.

An oil filter is a device that will remove physical impurities from dirty oil, and will retain those impurities until they are removed by some outside means, therefore, a filter that successfully performs these functions requires periodic cleaning. Whether a filter be classified as good or bad depends almost as much upon its easy accessibility for inspection and thorough cleaning as on its capability for purification. In the selection of a type of filter for any class of service, it is important that its arrangement for accessibility be given much attention.

In view of the ever rising cost of lubricating oil and its enormous consumption in the operation of the present day industry, an efficient lubrication and filtration sytem, with its wonderful economical possibilities, is being welcomed as most necessary engine room equipment. Correct lubrication for the increase of plant efficiency is being acknowledged as a science.

The importance that scientific lubrication is playing in our industrial management is evidenced by the disposition on the part of large concerns toward the employment of expert lubrication service. Their duty is to search out power losses, correct wastes in the use of oils, to save time and labor by the prevention of bearing troubles, and to insure at all times more power at less cost. The central oiling and filtration system, delivering flood lubrication of a correct oil mechanically, gives just this kind of service and performs its duties automatically.

There is very little doubt that the question of lubrication in power plants is receiving more careful attention than it has in the past. There are many reasons for this, among which are the increasing demand for, and the greater cost of, oil. Lubricating oils as marketed today are the result of years of experiment, and little improvement can be hoped for in the oils themselves. The field which promises maximum results regarding efficient lubrication lies in better and more scientific methods of application, the selection of the proper grade of oil for the purpose and the reclamation of used oils so far as this is possible. While the cost of lubrication may appear small in proportion to the total production cost of power, poor lubrication and inattention to the proper use of oil will assume an importance out of all proportion to the cost of a suitable oil and attention paid to its application.

The logical solution of these conditions is the use of a central oiling and filtration system.—Power Plant Engineering.

The American Engineering Company Philadelphia, have issued a new bulletin entitled, "The Central Station and The "Taylor Stoker" which describes and illustrates very fully a number of installations in public utility plant. A double page illustration of four great cities Taylor stoked is very effective, while there is a detailed description of the apparatus at the back of the catalogue.

The Drake Non-Clinkering Furnace Block Co., Inc., New York, have issued a catalogue describing their product, and its application to various styles of stokers and furnaces. The stoker applications include practically all the well known types in general use, and the results of a comparative test carried out on two B and W boilers with and without the blocks is included. A list of users of the blocks is given on the back page.

An Unexpected Result

AN ACCIDENT which resulted in the death of ten persons and a large amount of property damage was recently caused by the carelessness of a workman in taking a cover off a gasoline tank. This car contained a particular highly volatile type of gasoline, known as casing head gasoline. The gasoline is also known, according to the "Traveller's Standard" which describes the accident, as "wild" or "natural gas" gasoline.

Thec causes which led up to the disastrous effect seem to have been the omission of certain precautions, and the commission of grave errors. There is a safety valve on each gasoline tank car, which is supposed to lift at a pressure of 25 lb. per square inch, but which is also, according to regulations, supposed to be slacked off before the cover is taken off the dome of the tank, thus releasing all pressure that there may be inside. The workman who was detailed to unload the car first neglected to release this valve, and therefore the pressure, and secondly, on attempting to turn back the cover of the dome with a bar, and not succeeding, took a hammer and chisel to start the cover back. This practice is specifically forbidden by the regulations. When the dome cap was started, the gasoline being under pressure, forced some of the vapour through the cap, and a spark presumably from the chisel, ignited this vapour, with the disastrous result already mentioned.

It seems that no amount of warnings, regulations, or propaganda can ever imbue men with a sense of responsibility, or keep it alive in them day in and day out. It is probable that this man who was doing this was fully aware that he was breaking a regulation, and it is quite probable that he had done so before, and thought he could save a little time or a little trouble by disregarding it on this occasion. He not only lost his own life but caused the death of others, and huge damage besides. In most cases regulations are made for the purpose of protecting life and property, and are made after due consideration of their effects as regards retarding work. This loss of time is considered of less importance than the danger that would ensue if the regulation was not there. It seems to be inevitable however, that familiarity shall breed contempt in the minds of those who should be governed by these regulations, and sooner or later their contempt is visited by some calamity. This carelessness is not confined to any one industry, but can be found almost wherever men are engaged in occupations that carry a hazard of any kind. Even power plant men are not immune to this form of carelessness, and it is not unusual to find guards around eccentrics or crank webs removed for some repair, and never replaced. It is not unknown either for electric station operators to be killed by working in narrow places on live wires which could have been switched off with a little expenditure of time or trouble. The remarkable part of the whole thing is that men who would ordinarily kick loud and long if ordered to do any dangerous thing, will of their own free will break regulations made to safeguard them, for the sake of saving themselves a moment's inconvenience. The safety movement may not be always conducted in the most wise or effective manner, but it has performed and is performing a great service. It seems, however, that nothing short of a change in human nature will ever have the best results, and as some short-sighted reformers have found out, human nature cannot be changed by regulations or laws, however well meant.

Uniform Boiler Laws

WE UNDERSTAND that there is once more an effort being made by some of the various provincial authorities, to obtain a uniform law covering the construction of boilers throughout Canada, and including of course the various fittings and mountings comprised in the complete boiler. We have commented at various times on the desirability of such laws, not only for Canada, but also for international purposes. Why there should be any difference in boiler construction regulations is hard to see, because there can be only one correct standard, and that is the highest. There is but little difference in the laws of the various provinces of Canada, but in the States conditions are much more chaotic. The American Society of Mechanical Engineers has formulated a code, which we believe is high enough in its requirements to satisfy the conditions in any State, but we are not aware that that code is compulsory in every State.

There are some authorities with such wide experience and knowledge of conditions that their rules commend themselves to all people as being all that is desired. The oldest authority and the one with the highest standards and widest experience is probably the British Board of Trade, and this authority has recently enacted an improved code for boiler construction, after deliberations by the leading engineers of several of the great classification societies, in collaboration with the Board's own engineers. The various rules of the Canadian provinces are largely based on the Board of Trade rules as they existed at the time of the formulation of the provincial rules, and we cannot imagine that the provincial authorities could do any better than to adopt the Board of Trade rules in their entirety. This would make a uniform rule not only in Canada, but in most of the British Empire. These rules have immensely better backing behind them than any rules made by a provincial authority, as these authorities

are as a rule, merely local. In a matter of this kind, it seems to us that local pride might well take a back seat, and the general good of the engineering industry be considered. We cannot help feeling that any body of engineering talent which might be gathered together in Canada to consider this question, could not formulate a code which would be in any way superior to that promulgated by the Board of Trade, and the adoption of a recognised authority's requirements would smooth out any feelings of local jealousy that might crop up between the various local representatives.

Why Not a Dominion Wide Certificate?

IN conjunction with the effort to establish uniform laws for boiler construction, would it not be a good idea to obtain uniform laws for engineers' certificates? Is there any real good reason why one province of Canada should refuse to recognize the qualification granted by another one? Well, we would admit that at present there is, but that condition is fast being adjusted. The requirements of each province are gradually coming nearer and nearer to each other, and the policy of the closed door between provinces is losing whatever excuse it had.

Now the same objections are operative when discussing uniform regulations for engineers as are in force when discussing uniform regulations for boilers. They are, chiefly, the petty jealousies of local authorities, who will not admit that the other party may have as great a share of wisdom as themselves. Their own prestige is the thing that is paramount with them, and not the good of the great body of engineers or the good of the engineering industry. If this were not the case uniform construction laws would have been in force long ago, instead of still being in the talking stage. It is probable that before any real result is arrived at, the matter will have to be taken out of the hands of provincial authorities altogether, and handled by a Federal Government department, just as the marine regulations are handled by the Department of Marine. We are a very much governed people in Canada, and the multiplicity of Governments and authorities under those Governments leads oft to confusion. There are some things that are better for the sake of all concerned to be put under a central authority.

How does the engineer stand today, with the different Provincial regulations? He may obtain in the Province of Ontario, a certificate which entitles him to run a plant of unlimited size. Having obtained that certificate, he may decide that some other part of Canada offers him a fairer field, or we may say larger opportunities. He finds on moving out of Ontario, that he may be granted a temporary permit of the same, or more likely a lower grade, and after a certain period, he must present himself for examination in his new province. Now he is not only up against the proposition of passing an examination which may be made three times as stiff as the one he has already passed, but he is confronted with local influences and local prejudices which may effectively prevent him obtaining the certificate, no matter what his ability is. One may say, "Oh, the examining boards are above such petty feelings." Well, perhaps they are, but not all of them all of the time. Suppose a local man in a town, well known to the examiners and most of the engineers, and popular with both, is after a certain position. Opposed to him is a man from another province, whose ability to land the job depends only on his obtaining the local certificate. How much chance has he to obtain the certificate, and although he may eventually obtain it, is it probable that he will do so in time to beat the local man out?

This may be a very desirable thing from some points of view, and there are perhaps many men who would exclude engineers from other provinces altogether and make the stationary engineering profession a closed circle, keeping those in, who, are already here, and keeping all others very much out. That is not, we think, the general attitude. The average man likes to think that he can hold his own against all comers, without special legislation to help him out. Besides, a man never knows what urgent reasons there may be for him to move his home to another province, when his ability to earn a living at his chosen profession will depend on his ability to obtain a certificate.

There have been cases where men from outside of a certain province have been deliberately refused the opportunity to even sit for examination, because there were a large number of local engineers out of positions. There have been cases where the man from outside has been refused a certificate because the authorities felt there were too many outsiders coming into the province. They may have been all right from their point of view, but should it be in the power of any authority to interfere with a man's freedom to work where he chooses if he has the ability? As long as each province has its own governing authority it is inevitable that there will tend to be discrimination against men from outside the Province. Would it not be fairer for everybody, if, when a certificate was once granted, it should be good all over Canada? This would be easy enough to arrange, and easy to handle, and would result in a higher standard all round. There need be no increase in cost to anybody, and there should if anything, be a reduction in the fees to be paid by the candidate for a certificate. The fees charged in some of the provinces to day are out of all proportion to the value of the certificate when it is obtained, and the salary that can be earned by its possessor. The reason that the fee is so high is that a comparatively small number of engineers have to pay the salary and expenses of a comparatively large number of examiners and their staff. In some provinces these examining boards do nothing at all but hold examinations, while another body looks after boiler inspection work, and still another body after general factory inspection. There is no good reason why the surveyors or inspectors of engines and boilers should not be examiners, as they are in the Department of Marine in Canada, and the British Board of Trade. This would tend to economy, and furthermore, the expense could be borne proportionately more by the boiler owner, who is much the better able to bear it, than the none too highly paid engineer. The vexatious renewal rule, which is merely a method of collecting revenue, and serves no other purpose, could be abolished if the certificates were Dominion wide in their scope, and granted by a central authority. If a man is capable of running a plant of a certain capacity in the year 1920, he should not have to pay a fee for a certificate saying he is fit to run it in the following year. Unless he commits a serious breach of regulations, or is proved incompetent in some manner, he should hold his certificate for ever, if once obtained.

Supposing all the representative bodies from the different provinces met together and drew up a code of qualifications, covering third, second and first class engineers. As a matter of fact, two grades ought to be quite sufficient, because the third class certificate is practically only a fireman's qualification, and it is in the opinion of many people, somewhat of an injustice to make a fireman carry a certificate at all. However, whether two or three grades were decided on, this committee could frame standards of examination which would be acceptable to every province concerned. These regulations could then be submitted to the Federal Government, to em-

body in a Federal law, and endorsed by a Federal certificate. The provincial staffs could still carry out the examinations for the Dominion Government, in addition to their other duties, and examination fee could be divided pro rata between the Dominion Government and that of the province in which the examination was held. The staff at Federal headquarters could be of the smallest possible dimensions, that is allowing for the fact that it is a government department. Its duties would practically be only those of recording and registering the certificates issued. The examiners in the different centres would have no possible reason for discriminating between candidates, as a successful candidate might be as likely to travel away from his own district as to stay in it. The examination fee could be considerably reduced, as the examining board's staff could be used for the purposes of boiler inspection, which would furnish enough revenue to carry them. The renewal system could be dispensed with entirely. Incidentally, the examination could be made of a higher standard and that standard enforced, as it is not at present, in many cases. Every engineer throughout the Dominion would be on equal footing, and if he went out of the Dominion, a certificate granted from a Dominion authority would carry a much greater weight with foreign countries or other parts of the British Empire than a certificate granted by a local authority.

The objections to such a scheme, would no doubt, come from those provinces which have at present poor or no regulations for the examination of engineers. It is a scheme that should commend itself to engineers in general, and could be worked out without inflicting any hardship on anyone. After Dominion regulation came into force, all those holding certificate from a provincial authority that had formerly issued certificates, could exchange them for a corresponding certificate isued by the Dominion. Those in charge of plants in provinces where there were no regulations in force could be allowed to continue in charge of those plants for a period of twelve months, on a special permit, and come up for examination after that time. In the case of men who had supervised plants for five years or over, a certificate of service could be issued which would be good for the remainder of their working days. There would be other details to be worked out, but nothing of a very difficult nature. The Federal authority would have to maintain a small staff of inspectors who could drop in, preferably unnanounced, on the various local examiners, from time to time, and see how the examinations were being conducted. This would keep them on the mark. On the other hand, an engineer who thought he had a grievance, could take his case to the Federal authority, which would investigate it impartially. As it is at present, a man who thinks he has been unfairly treated has no appeal at all, unless he can, by devious means, gain the ear of the Minister who is above the examining board.

There may be other objections to such a method of qualifying engineers, but the suggestion is put forward here for what it is worth, and comment is invited from those interested.

A Study In Contrasts

THE FIRST public railway for steam locomotives was opened between Stockton and Darlington, England, by Edward Peese and George Stephenson on September 27th, 1825. This event caused great excitement, and nearly everyone prophesied that the "iron horse," as the engine was called, would be a failure. The train weighed about 90 tons, and consisted of six wagons loaded with coal and flour. Then came a covered coach which held the directors and proprietors, with twenty-one coal waggons fitted up for invited passengers, these numbering nearly 600. Stephenson's engine, which was named the "Locomotion," had a ten foot boiler and weighed not quite 1,500 pounds. As six miles an hour was supposed to be the limit of speed, it was arranged that a man on horseback should ride on the track ahead of the engine, carrying a flag.

The train was started without mishap and many of the spectators attempted to keep up with it on foot, some on horseback galloping across the fields to accompany this new means of transportation. After a few minutes Stephenson got impatient and shouted to the horseman with the flag to get off the track, for, to use his own words, "I am going to let her go." Spectators and passengers were alike afraid, but hung on tight while Stephenson opened up the throttle. Soon he was going at 12 miles an hour, later finishing with a glorious spurt at the rate of 15 miles. Spectators were left far behind, and one newspaper reporting the incident said that the performance had exceeded even the most sanguine expectations.

Compare this first locomotive with the modern type which is capable of eating up distance at the rate of 82 miles per hour. Hundreds of improvements have been made in addition to that in speed until at present we have a carefully prepared and massive piece of mechanism which excites wonder even in the heart of locomotive men themselves. The latest achievement in locomotive history is the "Thinking Engine."

The danger of collision has been ever existent, and unfortunately has been the means of a heavy loss of life. Some weeks ago, A. R. Angus, an Australian, demonstrated in London, England, a new device which he has invented, and which makes the locomotive so safe from collisions that he named the engine the "thinking locomotive." Three tests were made. In the first, two locomotives going head on towards each other at great speed on a single track were automatically stopped on approaching the danger distance without the intervention of the engineer. In the second test a locomotive heading towards another standing still on the same track was similarly stopped, and in the third test a rapidly moving locomotive overtaking one moving slowly was stopped.

On another page we give a brief description of the device. The thought, however, which remains uppermost in our minds is that marvellous inventions are continually being perfected and yet attract practically no attention. Here we have a life saving device which practically eliminates the human element, yet we sit back and take it all for granted. It is to be hoped the invention proves a success and a commercial possibility, so that all engines may be equipped with this added safety measure. The present safety condition of our railroads is excellent, but anything we can do to make them fool-proof, so far as switch operators are concerned, would be well worth while.

IT IS REPORTED by a British investigator, Mr. F. G. Cawston, who has been studying leprosy at Durban, that the administration of colloidal antimony appears to produce good effects. According to the British Medical Journal, he found that lepers in an advanced state of the disease, with all of their fingers and toes suppurating, were helped to such an extent by this treatment that the suppuration entirely ceased.

Progress in New Equipment

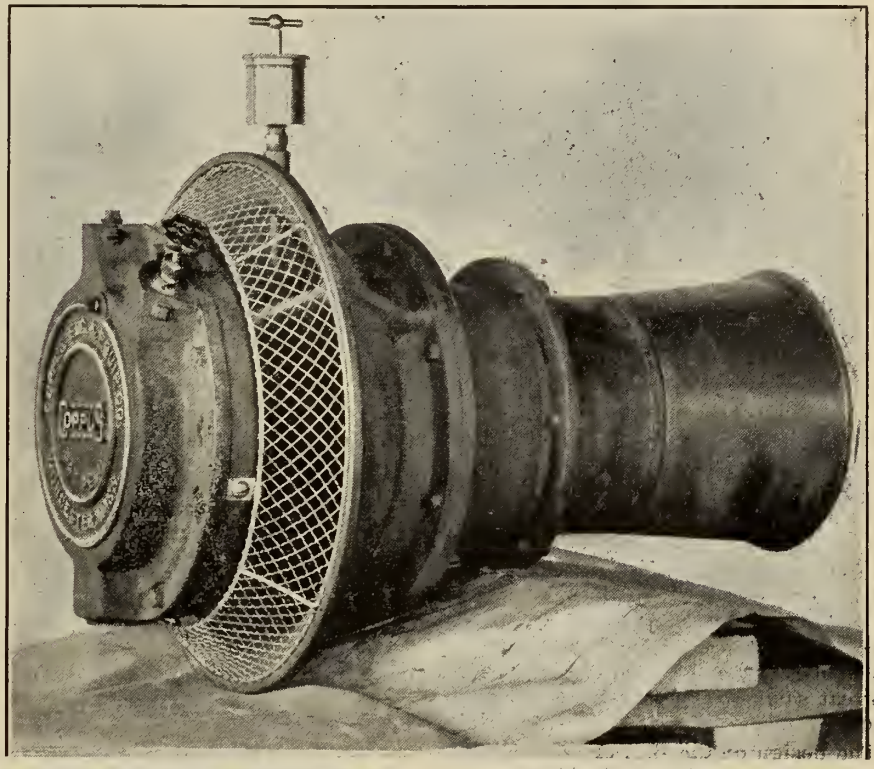
COPPUS VANO BLOWER

The field of usefulness for propeller blowers, until the advent of the Coppus VANO Blower, has been very limited. With the exception of low duty ventillating fans, propeller blowers have been used almost exclusively for undergrate draft on hand fired boilers or with chain grate and overfeed stokers, on account of their low efficiency at higher pressures.

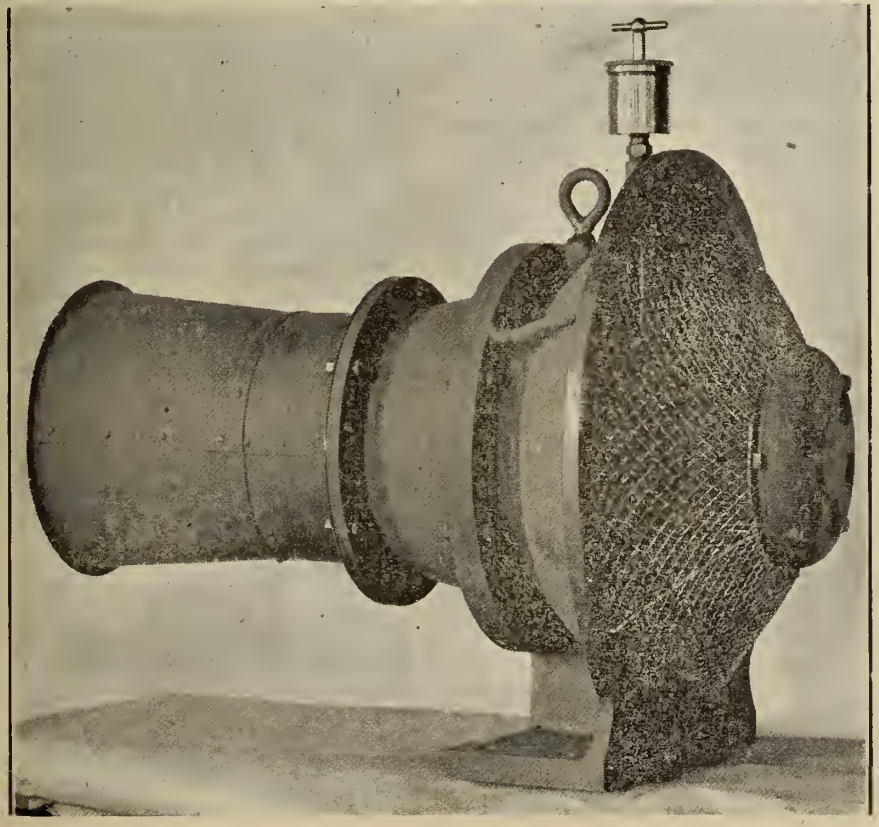
Coppus VANO Blowers are screw-blade propeller blowers which deliver the air parallel to the axis—in other words, the air leaves in the same direction as it enters. They differ, however, from all other propeller blowers in the following three points;—

1. They operate against pressures up to 8" water and, therefore, can be employed where, until now, only centrifugal blowers could be used.
2. Their efficiency runs up to 80%.
3. The power consumption AT CONSTANT SPEED is practically unaffected by variations in air delivery or pressure.

The principal feature of the Coppus VANO Blower is the stationary guide vane of peculiar design beyond the propeller. The air current leaving the propeller is radially sub-divided by the individual guide vane blades and taken up by them without shock. The guide vane blades which have a curvature, increasing in the direction of the rotation of the propeller, concentrate the air current and give it a further acceleration inside of the stationary guide vane so that a considerable part of the end thrust is thus taken up by the stationary guide vane casing. The air streams, into which the flow of air has been sub-divided by the guide vane blades, leave the guide vane casing, on account of the kinetic energy, slightly rotating and convergent toward the axis so that the smallest section of the air flow is reached beyond the guide vane casing.



Blower With Turbine Drive



Blower With Motor Drive

On account of the three principal features enumerated above, these blowers are adapted to many uses as:—

Undergrate or forced draft for hand fired boilers, chain grate, overfeed and underfeed stokers.

Induced draft.

Main—and individual room or tunnel ventilation for mines.

Air heating and drying installations.

Cooling of electric motors and generators.

View of guide vanes.

Ventilation of factories, boiler rooms, ships, tunnels, etc.

Coppus VANO Blowers have an efficiency as high as 80% for both high and low pressures. The power consumption is, it is claimed, much smaller than any other type of blower of the same capacity and pressure. On account of this in case of an electric drive, much smaller sized motors can be used, which means a great saving in first cost and in operation.

The design of the Blower is such that the air enters and leaves the blower parallel to the axis. They are high speed machines, which require a comparatively small driving unit. As a result of these features and the compactness of design, the blowers can readily be installed in pipe lines, which is a distinct advantage in ventilating, heating and drying systems. They work with the same effect and efficiency when installed at the entrance or at the end of the air duct operating as blowers or exhauster, respectively.

To deliver air through very long pipe lines, high initial pressure is necessary, as it is impossible in mine practice for instance, to keep air ducts tight, especially at the joints, the losses on account of leakage which, of course, increase with higher pressures, are often many times the actual air delivery at the discharge of the pipe. Instead of using a centrifugal blower delivering a certain capacity at, for instance, 12" pressure, three Coppus VANO Blowers delivering the same amount of air at 4" pressure can be installed on series equi-distant apart in the pipe lines or air duct. The losses through leakage are thus reduced to a fraction of the losses at high pressure.

Coppus VANO Blowers allow the reversing of the direction of rotation which changes the direction of the flow of air through the blower. In such a case, they deliver from one-third to one-half of their normal capacity.

The most remarkable feature claimed for the blower is the constant power consumption at constant speed practically unaffected by air delivery and pressure. The power consumption of a propeller blower increases very materially with increase in pressure whereas with centrifugal blowers, the horse power curve rises rapidly with decreasing resistance. As in very few installations the required pressure is known exactly before hand, it is necessary with electric driven machines to select motors with ample reserve capacity to prevent overloading and subsequent burning out of windings. Coppus Vano Blowers, consume practically the same power with entirely closed outlet or discharging freely into the atmosphere.

For forced draft installations on automatic stokers, at the present time usually a large engine, turbine or motor driven fan is used, discharging in an air chamber sometimes common to a number of stokers. From this wind box the air is conducted through individual ducts to the different stokers or stoker compartments.

A large central fan naturally runs at a slow speed which requires, in case of electric motor drive, reduction gears. On account of the above reasons, such an installation is very expensive.

For power plants with continuous operation, a complete second unit has to be provided for reserve. To illustrate this point, we will assume the maximum air requirements for a stoker are 100,000 cubic feet per minute and to make the operation of the plant entirely reliable, 120,000 cubic feet of air would have to be installed in case large central fans are used.

Six No. 500 Coppus Vano Blowers delivering 20,000 cubic feet of air each into a common wind box will do the same work more effectively at far lower initial cost and with increased dependability of operation. For maximum air requirements, five blowers will be in service and in case the plant does not work at maximum capacity for twenty-four hours a day, four or three machines may supply sufficient air during a large part of the day whereas the other machines are standing idle and do not use any power. The sixth machine is kept as a reserve unit. To get a reduced capacity with a large central fan, the driving unit operates at lower efficiency.

In case of a break down of one of the blowers, the necessary repairs are easily accomplished in an hour's time if only a few spare parts are kept in stock. Repairs to a large central unit may easily require several days, thus the installation of six blowers delivering 120,000 cubic feet per minute will secure the highest dependability of operation.

THE WILMON VACUUM TRAP

The novel vacuum trap shown in the illustration, was first perfected during the war and applied in marine service on the S. S. Leviathan by the then Chief Engineer, Commander Vaughan V. Woodward, U. S. Navy, as a means for draining the two low pressure turbines, replacing the customary main air pump drainage of these two large engines.

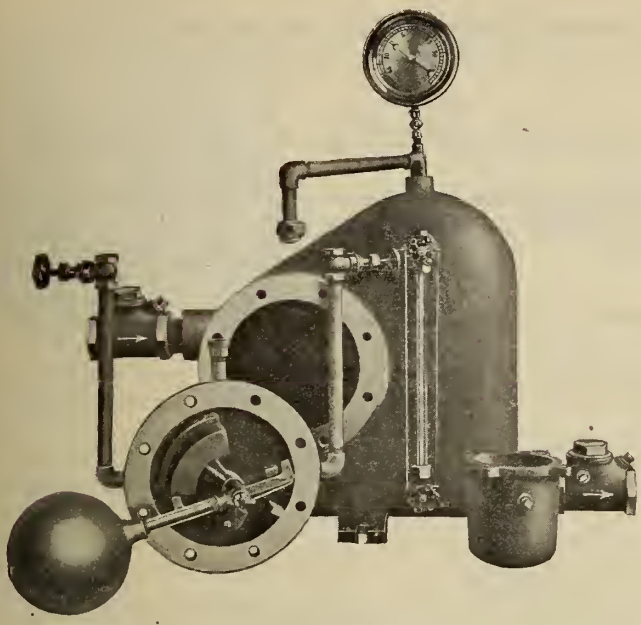
The trap is also suitable for draining apparatus and systems using steam under vacuum, such as condensers evaporators, vacuum pans, cooking kettles, etc., and for returning condensation of live steam heating systems to the boilers. Its use in place of a float controlled condensate pump is often practical and with a consequent elimination of the steam requirement for operating the pump.

The Wilmon Vacuum Trap, as it is called, can also be used for lifting, and when equipped with a counting device, it will perform the additional function of a meter and with greater precision.

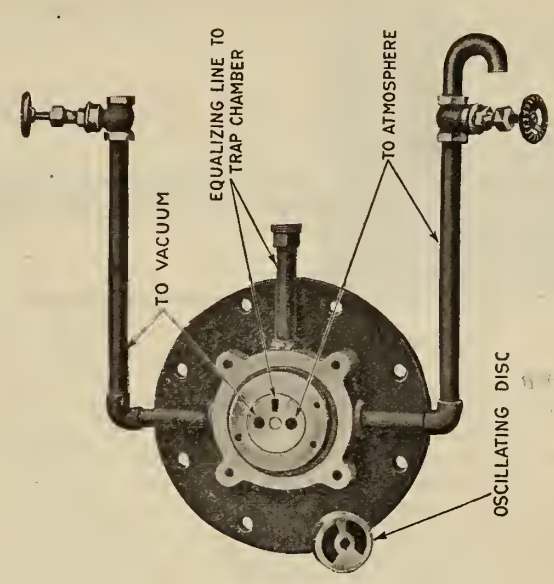
Typical drainage of a steam turbine with the delivery of the condensate at a higher point of discharge is shown in the line cut. In marine installations, where the common practice is to drain the turbine directly into the main air pump, hot vapors must enter the air pump during a part of the time and thereby impair the vacuum. By the use of the Wilmon Vacuum Trap the turbine drains can be removed entirely from the main air pump and placed through the trap into the condenser, thereby insuring that no hot vapors enter the air pump to interfere with the vacuum.

With the exception of the cover bolts, this trap has but thirteen parts, and by removing eight tap bolts, the entire working mechanism, mounted on a flange, can be taken out as a unit.

A compound pressure gauge on top and a sight glass on the front, give a double check on the operation of the trap. Where a permanent record of the



Trap with cover and float mechanism removed.



Showing controlling mechanism.

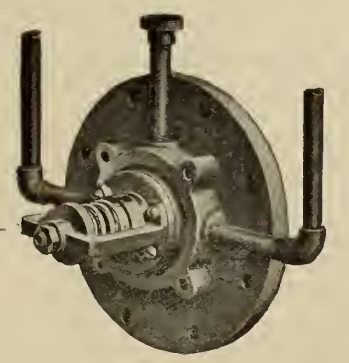
operation of the trap is desired, a recording gauge with electrical contacts may be added.

The receiving chamber of the trap is under vacuum while the water is collecting in the trap, and under atmospheric pressure during discharge. Back flow is prevented by check valves on the inlet and outlet lines.

Change of pressure in the receiving chamber from vacuum to atmospheric and vice versa, is accomplished by an oscillating disc covering three ports, which makes a quick shift from one operating position to the other. One of these positions connects the receiving chamber with the vacuum system, and the other position connects the chamber with the atmospheric line, the communication being effected in both instances through the equalling line which connects the middle port to a top opening in the receiving chamber.

The disc and thrust bearing, and the spring which holds these parts in place are in a separate outer chamber, where they are never in contact with the liquid within the receiving chamber. The disc is operated by a level float, hammer weight and rocker arm, all on the same shaft and located within the receiving chamber.

Water entering the receiving chamber carries the float upward as the level rises, and a contact point on the float stem, between the float and its fulcrum, rotates the weight, until as the latter passes dead centre, it drops onto the contact point on the rocker arm and partially rotates the oscillating disc to the opposite position. This shuts off the vacuum line and opens the receiving chamber to atmospheric and equalizing lines. Water is then forced through the trap outlet, if the latter is connected to a vacuum, or drains by gravity if connected to atmosphere. As the float falls with the water level, the contact point beyond the fulcrum on the float stem lifts the weight past dead centre and lets it drop in the opposite direction, when it hits the opposite end of the rocker arm and shifts the disc. This cuts off the atmospheric line, connects the vacuum and equalizing lines and brings the receiving chamber under vacuum again. The cycle repeats at a



Disc and seat showing controlling parts and operation

rate determined by the amount of water accumulating. More than three discharges per minute have been obtained with perfect action. The disc requires no adjustment either before trap installation or during service, but may be seen and reached while the trap is in operation, without in any way interfering with the trap action.

The absence of liquids at the controlling ports permits salty or alkaline water to be handled without fear of salting or eroding the operating mechanism.

The fact that the liquid passes through no restricted passages gives the trap a very high capacity, which is limited only by the size of the inlet and outlet openings of the trap. The 2-inch trap, for instance, handles 1800 to 2100 gallons of water per hour. This capacity will vary depending on the lift of the discharge.

The Wilmon Vacuum Trap is manufactured by P. H. Gill and Sons. Forge and Machine Works, Brooklyn, N. Y.

Watson & McDaniel Philadelphia have issued a bulletin describing their Watson Single Seat Pilot Operated Reducing Valve, for steam or air service. The bulletin is well illustrated and a detailed description of the valve and its operation is given.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

TEMPERATURE OF COMBUSTION

Question:—What should be the lowest temperature in a furnace when combustion is taking place?

Answer:—It is rather difficult to say what could be the lowest temperature in a furnace when combustion is taking place. For instance when a fire is banked, combustion is taking place, although slowly, and the temperature of the furnace except just over the fire that is banked may be very little higher than the stoke hold atmosphere. The temperature of the fire when in full working condition will again depend on the amount of excess air being supplied. The theoretical temperature of combustion is never reached in actual practice, due to the varying conditions obtaining in the furnace. The following formula gives the approximate temperature that should be reached in an ordinary furnace.

Let C, H, O and W represent the percentages of Carbon, Hydrogen, Oxygen and water in a fuel, and F the pounds of dry gas per pound of fuel then the theoretical temperature T above the atmosphere will be (Kent)

$$T = \frac{616C + 2220H - 327O - 44W}{F + .02W + .18H}$$

Take coal of 77 per cent. carbon, 3 per cent. hydrogen, 3 per cent. oxygen, 3 per cent. water, and the dry gases per pound of fuel being 22 then

$$T = \frac{616 \times 77 \times 2220 \times 3 - 327 \times 3 - 44 \times 3}{22 + .02 \times 3 + .18 \times 3}$$

$$T = 2344.2$$

and supposing the boiler room atmosphere to be 60° the theoretical temperature would be 2404 degrees. Now if the excess air was 200% instead of 100% the temperature theoretically would be only one half or about 1,200, while practically it might drop to 700 degrees. Even under the best circumstances the theoretical temperature is never reached.

STEAM CONSUMPTION

Question:—An engine having a cylinder 14 inches x 36 inches, running 100 revolutions per minute, with a piston rod 2¾ inches dia., and 5% clearance. The terminal pressure is 53 pounds per square inch gauge. What is the consumption of water per horse power per hour, if the engine is 75 h.p.?

Answer:—Assuming that the compression is carried out in the usual manner we can neglect clearance, and assume that the cylinder is full of steam at the terminal pressure when exhaust opens.

The volume of the cylinder will be

$$\frac{14 \times 14 \times .7854 \times 36}{1728}$$ cubic feet, and the area of the piston rod can safely be neglected in a calculation like this. The weight of a cubic foot of steam at a gauge pressure of 53 lbs. will be .1569 lbs. then the weight of steam in the cylinder will be

$$1.16 \times 1.16 \times .7854 \times 3 \times .1569 = .497 \text{ lbs.}$$

say ½ lb. steam per stroke, and 200 strokes per minute gives 100 lbs. per minute and 6000 lbs. per hour.

The horse power of the engine would be with a terminal pressure of 53 lbs,. and a ratio of mean to terminal pressure of 1.7 giving a m.e.p. of 53x1.7= 90.1

$$\frac{14 \times 14 \times .7854 \times 90 \times 3 \times 200}{33000} = 252 \text{ H. P.}$$

and with 6000 lbs. steam per hour the consumption would be 23.8 lbs. per I. H. P. per hour.

If we take our correspondent's figure of 75 H. P. the consumption would be 80 lbs per I. H. P. per hour.

SAFETY VALVE SPRINGS

Question:—A boiler has two safety valves each 3½ inches diameter. The size of the spring wire is ⅝ inches square. What should be the allowable pressure on boiler, the grate surface, the diameter and length of spring.

Answer:—We are compelled here to assume at least one factor. We can find the grate surface from the area of the valve, and we can find the load on the valve either by assuming a spring diameter or by assuming a pressure per square inch and then finding the spring diameter.

If we take our correspondent's figure

$$\text{of } A = \frac{37.5 \times G}{P}$$

where A is the area of valve, G the grate surface, and P the gross pressure we can find the grate surface if we know the pressure, or find the pressure if we know the grate surface. The area of the valves will be 9.6 x 2=19.2 square inches, and if we assume a pressure of 140 lbs. absolute we get

$$G = \frac{19.2 \times 140}{37.5}$$

$$G = 71.6$$

The load on one spring will be that due to the pressure on the area of the valve or

$$9.6 \times 125 = 1200 \text{ lbs.}$$

Now one formula for the spring of a safety valve is

$$d^3 = \frac{S \times D}{C}$$

where d=diameter or side of wire
S=load on the spring in lbs.
C=11,000 for square steel
D=mean diameter of spring.

Then we can substitute and find the diameter of spring from what we have already. Thus

$$.625^3 = \frac{312000 \times D}{11000}$$

$$D = \frac{11000 \times .625^3}{1200}$$

$$= \frac{110 \times .244}{12}$$

$$= 2.237$$

That is a mean diameter of 2.237 or we might make it 2.25 in round numbers.

The compression of the spring depends on the fourth power of the size of wire, and cube of the mean diameter, and the number of coils.

The formula for compression is

$$f = \frac{D^3 x S x n}{f^4 \times a}$$

where f=compression of spring
D^3=mean diameter
n=number of cards
f=thickness of wire
a=2,000,000 for square steel.

We have the mean diameter, thickness of wire, and the constant a. Suppose we wish to have a compression of three inches to give the load then

$$3 = \frac{(2\frac{1}{4})^3 \times 1200 \times n}{(\frac{5}{8})^4 \times 2{,}000{,}000}$$

$$n = 8.3$$

This gives us 8 coils, not counting the two scarfed coils at each end, which are not free.

If we have 3 16″ between each coil when the spring is compressed, and there are 8 free coils this will be 1 5 16 space, and 9 x ⅝ is 4⅝, so that the height of the spring will be 5 15 16 when compressed, or 8 5 16 when free. The outside diameter will be 2⅞ inches.

The Operators' Point of View

HOME MADE FORCE HAND OR POWER OIL PUMPS

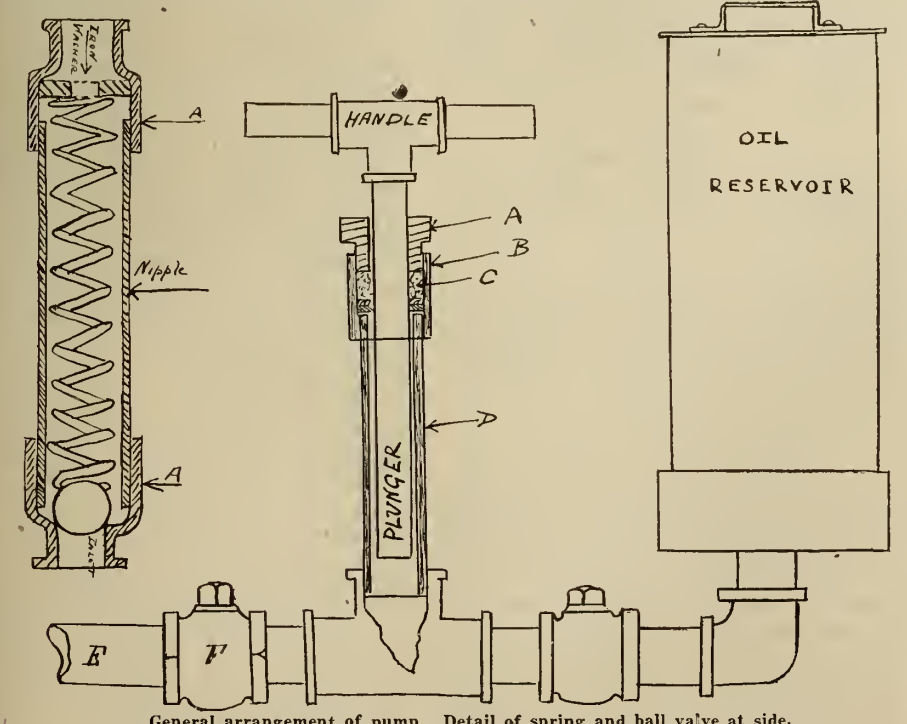
James E. Noble

A friend wanted a one quart size oil pump and upon inquiry he discovered the price to be from $9.00 upwards. The man who paid him his salary refused to invest this amount so the friend collected some pipe fittings and put them together in the shape shown in the sketch. I will not give any dimensions as the pump can be made any size with a ¼ inch plunger upwards. A is a bushing, B is a coupling, C is packing , under the packing is shown two iron or other metal washers, they prevent the packing working down into the cylinder D, which is a piece of plain iron pipe, it does not require a finished inner surface as the plunger is a very loose fit, the iron rod plunger should be made as smooth and true as possible on account of the tight joint necessary at the packing.

F and G are check valves. E is the discharge. The oil reservoir can be tin or galvanized sheet iron. The sketch shows a piece of large pipe with a bottom cap tapped to take the nipple, an ordinary tin cover on the tap.

As shown it is hand operated but the tee can be removed and a proper attachment used if it is desired to operate it by power. The reservoir can be set up on a shelf if the user would rather have it there, if the conditions are such that the oil will not flow out of the reservoir by gravity when the oiled machines are not operating.

Oil can be prevented from running from the reservoirs by gravity by adding a cut off valve between check valve G and the elbow, or a spring loaded valve can be used instead of check valve F. It is not difficult to make such a valve. Fig. 2 will give an idea for a home made one. A being reducing couplings, B. an iron or brass washer to hold the end of the spring, C the closing valve, consisting of a round ball, a nipple is between the couplings, a long thread being on the ball end. The inlet of course is at the ball end.



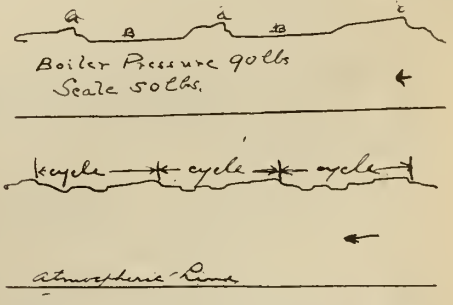
General arrangement of pump. Detail of spring and ball valve at side.

STEAM PRESSURE BOILER FEED PUMPS

By R. McLAREN

"In boiler-feed pumps the steam pressure available and the pressure pumped against are practically equal, so that it might be expected that the area of the steam piston would be made about 40 per cent. larger than the area of the water piston. In actual practice it is found, however, that pump manufacturers prefer to make the steam piston about three times the area of the water piston in very small pumps and about twice the area of the water piston in large pumps. The steam piston of boiler-feed pumps is made so largely in excess of what it really needs to be merely as a matter of safety; its large size simply tends to insure a prompt starting of the pump under almost all conditions likely to arise in practice."

With the above in mind I was curious to know what pressure there would be in the steam chest and therefore throughout the entire stroke of a duplex, direct acting, outside packed plunger pump whose steam piston is 7½ inch in diameter, water plunger 4½ inch in diameter and stroke 10 inch. The pump is controlled by a pump governor of a type designed to maintain a constant pressure in the feed line. An indicator was attached to the steam chest cover and by drawing the cord



Indicator diagram from pump steam chest.

out slowly and steadily while pressing the pencil to the paper, a chart was obtained showing the pressure in the chest over a period covering several cycles. A 50 lb. spring was used and it will be seen that at no point was the pressure up to 50 lbs. in the chest although it was close to it. Fig. 1 is the chart. The boiler pressure was 90 lbs. and the pressure in the feed line 110 lbs.

With the throttle closed so that the pump would move very slowly, Fig. 2 was obtained.

The governor was not by-passed, the steam having to pass through the governor and the partly closed throttle. At the points a a a the speed accelerated. At points B B the pump was apparently stuck. Can anyone explain why the pressure did not rise at points B when the pump was not moving?

CHART FOR PIPING

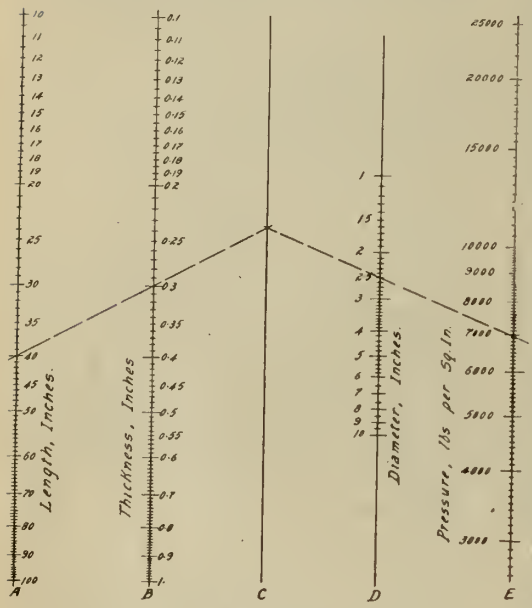
W. F. Schaphorst

The chart shown in the accompany illustration is one which is based on the formula that

$$P = 9{,}600{,}000 \frac{T2.18}{LD}$$

where P=the collapsible pressure in lbs. per sq. in.
T=thickness of metal in inches.
L=length of pipe in inches.
D=outside diameter of pipe in inches.

The chart is intended for solving piping problems without need of calculations, by the simple use of a straight edge as shown by the dotted lines.



Example — What external pressure will a 2.5 inch pipe safely with stand whose length is 40 inches and the thickness is 0.3 inch?

Run a straight line through 40 (col. A) and the 0.3 (col. B) and locate the intersection on Col. C. From this intersection run a straight line through 2.5 (col. D) and the intersection with col. E gives the result. In this case, 6950 lbs. per sq. in. The chart can be used to obtain any of the other factors by simply reversing the process.

VENTILATION RESEARCH

The Pittsburgh Experiment Station of the United States Bureau of Mines is working in co-operation with the Research Bureau of the American Society of Heating and Ventilating Engineers on a number of important problems which affect each individual in his home life, in his place of business, and especially in those places where many people congregate, as in churches, schoolrooms, and theaters. It is important to ventilate such places with sufficient fresh air to make everyone comfortable enough to be able to work at high efficiency. The circulation of excessive quantities of fresh air imposes a considerable cost on the heating system therefore an efficiently designed heating and ventilating system introduces the least amount of cooled air consistent with proper conditions for health. In this connection the use of ozone has frequently been proposed and actually tried in a number of places. The ozone is supposed to deodorize and purify the air by the oxidation of organic matter and possibly by killing bacteria.

It is however, a real question as to whether ozone can be introduced in quantities large enough to kill bacteria without producing very serious irritation of the throat and lung tissues. It is also a question as to whether harmful oxides of nitrogen are not produced simultaneously with ozone. Definite information is needed on this subject. The first step in obtaining such information is to work out methods for accurately determining the percentage of ozone and oxides of nitrogen produced for different types of ozone machines and to develop suitable methods for determining the very small quantities of ozone and oxide of nitrogen that may be in the air treated with such machines. Analytical work of the highest precision is required. The gas laboratory of the Bureau of Mines, Pittsburgh Station, is now engaged on this problem, working in co-operation with the Research Bureau of the American Society of Heating and Ventilating Engineers which is housed in the same building.

After the chemists have worked out the methods of detecting and analysing these small quantities of ozone and oxides of nitrogen, the next problem will be undertaken in a like co-operation of the two agencies just named working with the United States Public Health Service. Surgeons from this service are detailed to the Bureau of Mines for working on health and sanitation problems. The work is being carried on under the joint general direction of A. C. Fieldner supervising chemist and superintendent of the Pittsburgh tation of the Bureau of Mines, and Dr. R. R. Sayers, chief surgeon, Bureau of Mines, by G. W. Jones, assistant gas chemist, Bureau of Mines; W. P. Yant, assistant analytical chemist, Bureau of Mines; and O. W. Armspach, engineer, American Society of Heating and Ventilating Engineers.

WHY SAFETY WORK

We would like to think, perhaps, that the accident-prevention campaigns that have been conducted in our industrial establishments have been carried on for purely humanitarian reasons. Some of them certainly have had such a basis, and the number may be greater than any if us would be likely to guess. But in all cases it is, in addition, "good business" to maintain effective safety work,—whether that fact is recognized or not. Accident prevention is distinctly profitable, and if conducted in an efficient manner it yields big dividends on the investment.

The actual cash return from safety work is hard to determine, but that does not prove that there is no return and it does not prove that the return is small. It is almost equally hard, in many cases, to trace the actual cash return made by advertising, yet nobody questions the soundness of rational advertising as a business investment.

Some idea of the cash saving brought about by accident-prevention work may be had, by figuring the actual time lost per year on account of accidental injury. A first-class workman means certain amount of profit per day, and this amount, multiplied by the number of days lost a year on account of accidents, gives the actual loss covered by this one item. Any reduction in the number of days lost therefore means a direct saving in dollars and cents.

But saving is effected in other ways also,—and the additional saving is quite real, even though indirect.

An accident in a workroom upsets the organization by demoralizing the other workmen, and this means time lost. In a bad case a whole department may be temporarily shut down on account of the state of mind of the workers, and standard efficiency may not be again attained for several days. Somebody's time is also lost in caring for the injured man —removing him from the room giving him first aid treatment, taking him to his home, and doing other things incidental to making him as comfortable as possible. All this time must be included in figuring the cost of the accident, if a rational result is to be reached.

Again, a new man must take the injured workman's place, or take the place of somebody else who is shifted to the vacant job. The new man must be instructed by the foreman —which takes the foreman's time; and for a while the man will be below standard in his production —which is another source of expense. Not being familiar with the work in hand, he is likely to spoil considerable material while getting accustomed to the new place—and this is expensive, especially if he spoils pieces upon which other workmen have already spent a measurable amount of time. Moreover, the new man is presumably more likely to meet with an accident himself, than a more experienced man would be; and in this sense he becomes an increased hazard, and possibly a new source of expense.

The cost of an accident does not stop here, however. The injured man must be cared for while he is disabled, and even though this expense may be borne by an insurance carrier, the rate paid for such insurance depends in considerable measure upon the accident-frequency in the plant in question. If the accident-frequency is high, the insurance rate will be correspondingly high, and the insurance premium that is paid is one of the operating costs that has to be included in determining the total cost of production.

Safety work that has been carried on in times past will help in some measure to reduce the accidents of to-day.

but it must be remembered that although adequate safeguards may have been installed throughout the plant, the major part of the industrial accidents that occur are caused by factors against which mechanical safeguards provide little or no protection.

After the physical hazards are guarded, suitable action must be taken to see that the guards are constantly kept in place and are maintained in first-class condition. It then remains to protect the men from carelessness, lack of judgment, ignorance of existing dangers, and other factors entirely dependent upon the human element. This work can be done only by safety education, continuously carried on by an active organization;—which means that to keep industrial accidents at a minimum, safety work and accident-prevention campaigns must not be interrupted.

Statistics for the year 1920 show gratifying results in connection with safety activities in our various industries, and there is every indication that systematic safety work, in plants where it is being carried on, is producing positive and valuable results in the way of reducing the total number of accidents in industry in general. The good work that is being done in the establishments that are actively prosecuting it, is reducing accidents faster than they are increasing in other places where such work has never been instituted, or where it has been suspended for one reason or another. But that is not enough. Rational safety work actually shows a profit by reducing the costs of production, and no enterprising business man should be willing to give it up, any more than he would think of stopping his advertising or annulling any other factor in his business that has been proved to be a source of revenue. Men who have thought best to discontinue such work for the time being have probably failed to appreciate the indirect costs that such discontinuance introduces, and have centered their attention solely upon the more immediate and obvious items on the cost side of the ledger. Good safety work should be the last activity suspended, because it returns a profit (all things considered) which is it at least as great, in most cases, as the ordinary profit yielded by the business as a whole under normal conditions.—Travelers Standard.

WELDING BY CLOCKWORK

In shipbuilding and in many engineering operations, it is necessary to fix brass studs and other small parts to iron plate. This operation is usually performed by drilling holes in the plate, each hole being drilled separately. By means of a most ingenious invention recently perfected by a British firm, the process is carried out in a few seconds by electric welding. The working of the machine is almost entirely automatic from the moment the stud is placed in position. Each size of stud requires a different time for welding it to the plate, and the machine can be set to give exactly the period required to make a perfect weld. The tests which have been made proved that the machine is able to weld 120 brass studs within the hour. It might be thought that welding does not give such a firm arrangement as screwing the stud into a hole in the plate, but when the welded stud is hammered the brass will break before the weld yields. Another advantage of the machine is that work can be satisfactorily carried out by semi-skilled labor.

POWER FROM SEWAGE

It is often said that modern methods of sewage disposal are exceedingly wasteful, because they throw away material, which might be utilized to great advantage. Many of the systems developed in Great Britain are free from this reproach, and experiments recently made in the utilization of gas from sewage show that in an unexpected quarter British engineers are attempting to secure the highest economy. In one large British city a gas plant was installed to give 25 horse power for a working period of six hours per day. It is driven by gas generated from the dry solid matter produced in the process of sewage disposal. The experiment has been most promising, and it has revealed a useful source of power in a district where gas and electricity are not available. The power produced by the sewage gas is used to drive the plant which forms an essential part in the installation for purifying the sewage; thus it affords a most desirable form of economy.

BUSINESS MEN GIVEN GOOD ADVICE

In Mr. O'Connor's opinion, the business man of to-day is confronted with the option of sitting down to wait for the clouds to roll by, or to get up and push those clouds away. Mr. O'Connor is general manager of the Murray-Kay Co., Toronto, and the above remarks were given a few days ago in an address before the Lions' Club at Toronto. Among many other thing things he said, that manufacturers cannot put their spare money into tax free bonds, then go out and play golf or something else, and think that is going to save the situation.

"Such a plan is so ephemeral, and so obviously not the solution to any country's financial problems," remarked Mr. O'Connor, "that I am surprised that men who have built fortunes for themselves can become converts to it. Capital cannot exist in a strong box. The only place that capital can keep its life is out in the open. Nothing would be more fatal to any community than the common adoption by all who had savings of such a plan."

THINKING ENGINE IS TESTED CAREFULLY

In our editorial columns this week we speak of the "thinking" locomotive. This device automatically prevents railway collisions and nearly all sorts of railway accidents. The mechanism is controlled by electricty running at a very low voltage through the rails. The railway is divided into insulated sections of suitable lengths and the locomotive is provided with an induction coil placed two inches above the tracks. This "picks up" the current which, transformed into a higher power, magnetically sustains a weight in the engine cab. This weight, if dropped, will act on the locomotive's mechanism and bring it to a standstill, But the voltage is so low that it is sufficient for only locomotives and hence if two approach each other the current becomes insufficient and the weight drops, causing first a blowing of the whistle, second the shutting off of the steam, and third, application of the brakes.

Does not Depend on Human Element

It is stated that the installation of the new system on eight lines in England will begin immediately. The system operates even if the engine driver is drunk or asleep. The human element is only on the mechanic who controls the supply of current to the locomotives, but the worst that could happen from his carelessness would be a momentary suspension of the traffic.

Mr. Angus the inventor, claims that his system will greatly increase the safety of moving traffic on congested lines. Its novelty is the absence of any "shoes," "clamps," or other mechanical contacts which it is claimed have made all previous systems unsatisfactory. Finally Mr. Angus claims that the system is very economical; in fact he purposes to install it on the English railways free of charge, taking as his profit half of the resultant saving in the operating costs.

D. K. Chadbourne has been appointed Manager of the New York Office of the Westinghouse Electric International Company. Mr. Chadbourne came to the Westinghouse Company through the George Cutter Company before it was affiliated with the Westinghouse, as he was successively western district manager and eastern district manager of the latter company from 1912 to 1920, when he joined the Westinghouse Electric International Company.

The Conveyors Corporation of America have issued a bulletin describing the American air tight doors, which have been designed for service where a non-warping, airtight door is a necessity. Some of these places are ash-pits, boiler settings, coke ovens, oil stills, kilns, retorts, etc. The doors are used in connection with the steam jet ash conveyor made by the company.

Canadian Association *of* Stationary Engineers

Incorporated May, 1887
Incorporated at Ottawa June, 1917

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?

If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.

The undersigned will be very pleased to give any further information required.

F. HARPER, President Grand Lodge.
89 Bay Street, Kingston.

L. J. ELLIS, Sec.-Treasurer Grand Lodge.
142 East Avenue, N. Hamilton.

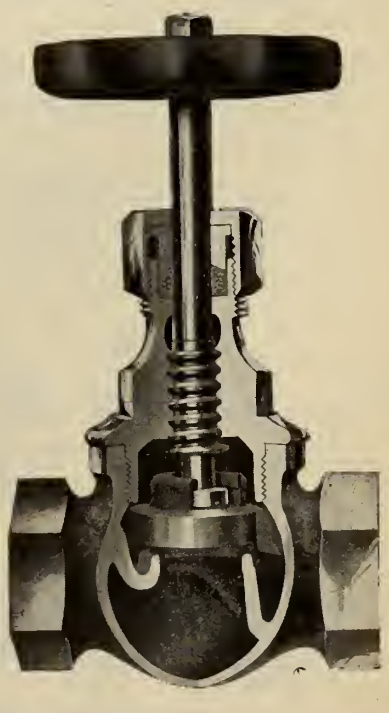
Fairbanks-Morse Valves

Reduce Maintenance Costs



A new disc can be put on in one minute without removing the valve from the pipe line.

The main features of this valve are:—

Stuffing box packed with Palmetto Twist packing.

At least four threads engaged with bonnet at all times.

Renewable Bakelite Disc can be replaced in one minute.

Raised round seat. No sediment can lodge on it to injure disc.

Guides cast on body hold disc centrally over seat.

The True Value of Work

SPEAKING ON "Work" the college paper, "The Varsity," gets away with these choice and true remarks:

After all, why should we work? Why spoil one's College course by going to lectures, and by plugging hour after hour at the writings of men who are dead and gone—we know where we should have sent them—when there are so many other activities that claim one's attention and interest? What's the use of it, when we know that a kind-hearted Providence has endowed one with brains enough to get over the year's work in the last six weeks and still get a very respectable third, or even a second? How often we reason thus, not so much at this time of year as later in the session. How ready we are to accept the old interpretation of the Genesis story and believe that Work was sent as a punishment for man's sin and that Heaven is a state of rest in which our tasks are all done and done with. It is well that at the outset of our year we should realize the fallacy of this view of Work. The Pauline dictum, "Let this be known among you, that if any man will not work neither shall he eat," is not only sound theology, but is also sound economics. Work is not an imposition, but a duty and a privilege, and the man who does not appreciate the fact that without real work his personality cannot gain full play, is indeed unfortunate. It is all right to work for a degree. It is better to work for the knowledge gained, but above all it is good to work for work's sake. The greatest happiness is the knowledge of a congenial and useful task well done and the prospect of another to be done.

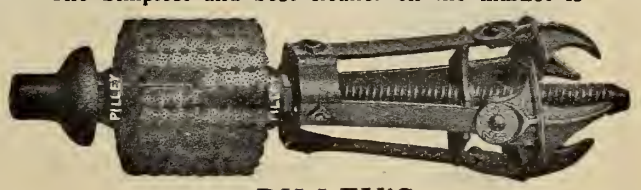
26 Craig Street - MONTREAL, CAN.

WATSON & McDANIEL CO.
No.146 N. 7th St., PHILADELPHIA, Pa.

The Simplest and best cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.

For sale by leading Canadian jobbers.
Manufactured by

PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.
Eastern Office: 71 Fulton St., New York.

Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap

Has important features which CLAIM your attention. Absolutely guaranteed. The Long Trap is automatic and requires no valves except those which control the admissions of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds. Being open at starting, it cannot become air bound, this doing away with air cocks or vents—Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one inch pipe.

The Long Trap may be applied to drain steam mains, jacket kettles and separators, and can also be used in drying room systems.

Write for further explanation to

Jenkins Valves

"I Know It's Good Because It's a Jenkins!"

The experienced engineer—the man on the job—knows the significance of the name Jenkins within a Diamond Mark cast upon the valve body.

He knows that it stamps the valve as a genuine Jenkins—that it assures quality metal in the construction, correct proportion at every point and long lasting, trouble-free service under the most severe conditions of usage.

Jenkins Diamond Marked Valves are made in types and sizes to meet every requirement of service everywhere. Every Jenkins Valve is *tested for maximum service before it leaves the factory.*

Copy of No. 8 Catalog (free on request) shows how very complete the Jenkins line is. Write for it to-day.

Let's Get Down to Business

SUMMER, with its dog-days, its vacations, its distractions, is over. We have had our holidays, our rest, our recreation. The Fall season, with its new opportunities for effort, enterprise and achievement, is upon us. Let us rip off our coats and get down to business. We may have allowed pessimism to grip us during the stagnant months of Summer. We may even have allowed laziness to enter our blood and our bones. It is now up to us to throw off both lassitude and pessimism. The time has come for action, for aggressiveness, for enterprise, for courage, for daring. Strong men make opportunities. Strong men do not supinely submit to conditions; they mold them. The business roadway has been cleared of almost all the weeds and rocks and swamp; begotten by the fatal war boom. The way is now open for a vigorous forward march. Let us cease looking backwards, let us cease bemoaning the hardships and the distress of the recent past. Let us look forward and let us go forward with confident unhesitating tread. Better times are within our reach if we will but reach out intelligently towards attaining them.—*Forbes.*

Is your packing as good as your flanges?

WHEN you order pipe flanges, you know that they will stand anything the pipe will stand.

Can you be as certain about the packing from which you cut the gaskets to pack these flanges? You know that if a gasket fails, you've lost much more than the few cents premium you might have paid for a better packing. For gasket failure almost always means a loss in time, labor and production that is out of all proportion to the initial cost of the gasket—amounting often to hundreds of dollars.

If you would be sure that your packing will render you the service you have the right to expect, cut your gaskets from Johns-Manville Service Sheet Packing.

Why Service Sheet makes the best gaskets

IN Johns-Manville Service Sheet we have produced a strong, thin sheet packing that resists heat, water and chemical solutions

Gaskets cut from Johns-Manville Service Sheet Packing are reliable because they are made of Asbestos Fibre, bonded with a heat-resisting compound; they practically eliminate joint failure because Service Sheet is not harmfully affected by superheated or saturated steam, air, water, ammonia, oil or most chemical solutions; they are so dense, yet resilient, that they can be used half as thick as compressible gaskets and make tighter, longer-lasting joints.

With Service Sheet, only one sheet packing, instead of several, is required for practically all conditions. This means that the minimum stock may be carried with less chance of using the wrong sheet for particular conditions, yet you need never be afraid to keep an adequate stock on hand because Service Sheet does not deteriorate with age.

Ask the nearest Johns-Manville branch for a sample and the booklet describing Service Sheet.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

DROP—FORGINGS
often cheaper than castings
—always far superior

WILLIAMS' SUPERIOR DROP-FORGED "Agrippa" Clamps

FOR medium service there is no better clamp made than Williams' "Agrippa".

Drop-Forged from strong, tough, selected steel and heat-treated after forging, there is little possibility of springing. Better tools make better workmen and the best workmen say Williams' "Agrippa" are best.

Seven sizes of 4 inch to 18 inch capacity.

Ask for Machinists' Tools Book which also describes Williams' Clamps for every purpose.

AMERICAN
THOMPSON
IMPROVED INDICATOR

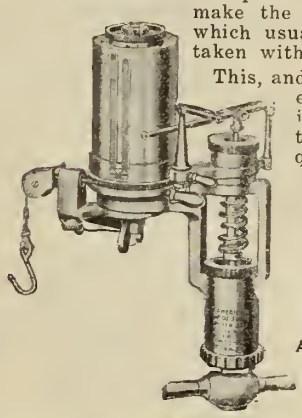
While your engine is running at top speed you can change cards on an American Thompson Improved Indicator in less time than it takes to talk about it.

With our patented design of Detent Motion two or more cards can be taken in the time ordinarily required for one. You don't have to unhook cord, and cord will remain at same tension.

American Thompson Improved Indicator

Is the only make with this Improved Detent Motion. And without this device it is a slow, disagreeable and often difficult task to take off one card and put on another.

The American is also the most accurate Indicator. Because of its limited pencil motion, it is impossible to make the errors in vertical lines, which usually exist in the diagrams taken with other Indicators.



This, and other features of the American are clearly explained in a valuable little book that will be sent free on request.

AMERICAN
STEAM GAUGE
AND VALVE MFG. CO.
BOSTON, MASS.
Atlanta Chicago Los Angeles
New York Pittsburgh

An Efficient, Low-cost Combination!

Mason Standard Reducing Valve Iron Body

Mason Valves

Mason Standard Reducing Valves reduce and maintain an even pressure of steam or air regardless of the variation of the initial pressure or of the volume of steam or air required. A special socket key permits them to be set to constantly maintain any required pressure within a wide range. Made in bronze for pressures from 5 to 300 lbs. In iron for pressures up to 180 lbs.

Write to our nearest branch for particulars of these or any other specialties in which you may be interested.

Stratton Separators

Where a thoroughly reliable and always dependable Steam Separator is required, the **Stratton** fills the bill! It is of the centrifugal type and thoroughly eliminates moisture without adding back pressure. Is simply constructed with large receiver capacity.

Ashton Pressure Gauges

Made in many designs for air, gas, etc. **Hand graduated** to insure absolute accuracy. Rigidly inspected.

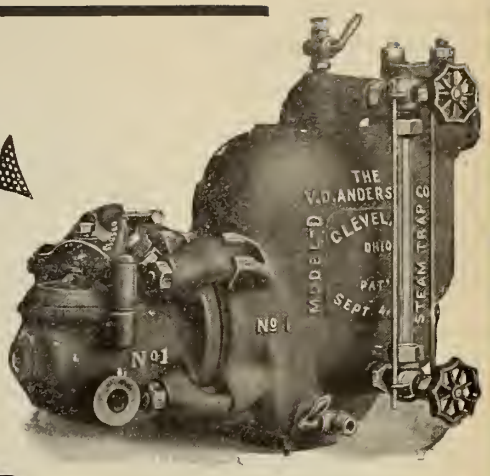
The Anderson
Model "D"
Steam Trap

Built to fit any Steam Line



You can use this trap on any line. Anywhere or everywhere there is condensation the **Anderson Model "D" Trap** will give you economical service. Because it absolutely prevents loss of steam some odd thousands of users are "strong" for this trap. It is the most effective trap because it automatically adjusts itself for any pressure within its capacity. Valves are built of wear-proof, rust-resisting materials. Equipped with a removable strainer which prevents scale, packing, etc., from entering the valve. Ask for catalogue.

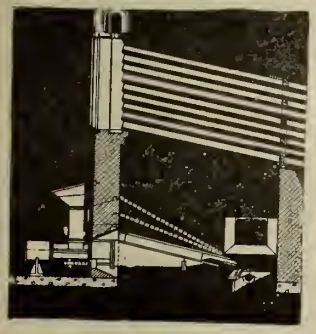
Instead of a crankshaft and a lot of complications, simple self-contained retorts.



Slight slope of Jones "A-C" retort compared with gravity feed retorts (indicated by dotted lines). Instead of gravity fuel movement, positive movement.

Jones "A-C" high side tuyeres (above) compared with ordinary type (below). Increases furnace width; keeps fire and clinker away from side wall.

The simple balanced dump plate easily operated by one man.

Simplicity—without a single sacrifice

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. The old-established Jones Under-Feed Stoker Company, Ltd., has recently been reorganized as the Under-Feed Stoker Co. of Canada, Ltd., and the reorganization makes available for Canadian Power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

Can you think of any piece of power plant equipment that is taxed as heavily and irregularly as the stoker? You can't expect a complicated, delicately adjusted device to withstand this hard grind—it's like expecting results from a race horse hitched to a plow.

The illustrations here show how the stamina of the plow horse is built into the Jones "A-C" without sacrificing the get-away and speed of the race horse. Or, to put it another way, how quick pick-up and overload capacity are combined with that sterling quality, rugged simplicity, that insures **staying power.** Consider the following exclusive Jones advantages:

Instead of a crankshaft with its connecting rods, shearing pins, gears, sprockets, chains, etc., a simple steam-driven retort with one sturdy moving unit—no moving parts in the fire.

Instead of an erratic gravity feed, a positive mechanical fuel movement. Note the slight slope of the "A-C" retort diagrammed above.

Instead of side wall clinker troubles, high air cooled side tuyeres that prevent clinker formations and increase grate area.

Instead of a "high strung" complicated power dump, a rugged dumping mechanism easily operated by one man.

These features merely brush the surface of Jones betterments clearly explained in the "A-C" catalog. Ask for a copy of the new edition.

TRADE MARK

"PALMETTO" PACKING

REG U S PAT OFFICE

may not be cheaper than many other rod packings, but it certainly gives much longer service even under extreme conditions.

After all—it's the length of service that really determines the value of a packing.

Let us send you working samples of both forms, so that you may try it out—no charge.

BRAIDED for rods.

TWIST for small valves.

Typical installation of ELESCO SUPERHEATERS.

How Much Can I Save?

"HOW much fuel can I save by the use of superheated steam?" is the first question that suggests itself to the man responsible for the coal bill.

From 10 to 20 per cent. is the average saving. It may run as high as 25 per cent. The more wasteful the present equipment the greater the savings possible with the superheated steam.

The use of superheated steam and the installation of Elesco Superheaters are matters for individual study.

After a thorough study of a plant and its conditions, Elesco engineers submit a comprehensive report covering the cost of the recommended Elesco installation, the additional capacity it will give, and the fuel and maintenance savings it will effect.

ELESCO SUPERHEATERS ARE
MADE in CANADA

A request for an Elesco analysis and report carries no obligation on your part.

LUNKENHEIMER
"Duro"
Blow-off Valves

"DURO" Blow-off Valves effectively meet the requirements of Boiler blow-off service.

The "DURO" *self-cleansing seat* insures tightness; reduces to a minimum the wear on the seating faces, prolongs their life, and prevents leakage which would impair the economical operation of the boiler plant.

The "DURO" disc is reversible, being provided with two seating faces, and the disc, together with all other parts are renewable. These advantages peculiar to "DURO" Blow-off Valves are the result of years of experience, which, combined with high quality materials and the LUNKENHEIMER method of manufacture, make them valves of unexcelled merit.

The LUNKENHEIMER Distributor in your locality can supply your valve needs. Acquaint him with the operating conditions of your plant. This knowledge will enable him to anticipate your requirements, preventing delay and possible shut-down when an emergency arises.

EQUIP WITH "DURO" BLOW-OFF VALVES.

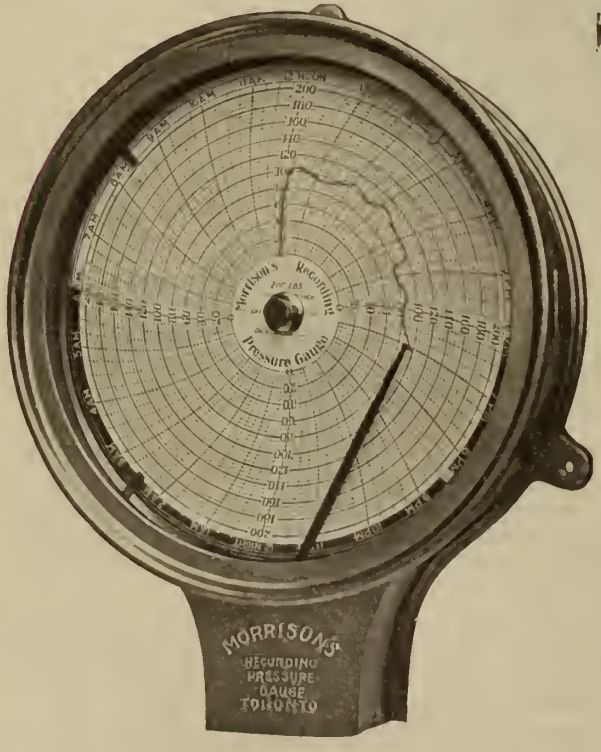
"This Record Proves My Point"

Records for Economy

The installation of Morrison Pressure Recording Gauges brings mutual benefit to the employer and the fireman. To the former it means "proof of lower costs." To the latter "proof of ability."

MORRISON PRESSURE GAUGES



take a continuous record of the steam pressure, indicating with precision all variations that occur for every hour of the day. They are the choice of both engineer and fireman because of their reputation for long performance and freedom from repairs.

Write us if you require Gauges for any purpose. Our instruments are of the highest quality and fully guaranteed.

Suitable for 175 pounds working steam pressure
or
250 pounds working water pressure

Made To Meet The Severest Tests

Every Jenkins Valve is made to withstand strains in excess of those which it will be called upon to endure in actual service. This is one reason why Jenkins Diamond-Marked Valves are always dependable.

The fact that every Jenkins Valve is subjected to a most severe service test before it is allowed to leave the factory is a further guarantee of long life and trouble-free service even where conditions of usage are more than ordinarily severe.

Jenkins Valves are made in all types and sizes for all uses.

The complete line is pictured and described in detail in the Jenkins Catalog No. 8 which will be mailed free on request.

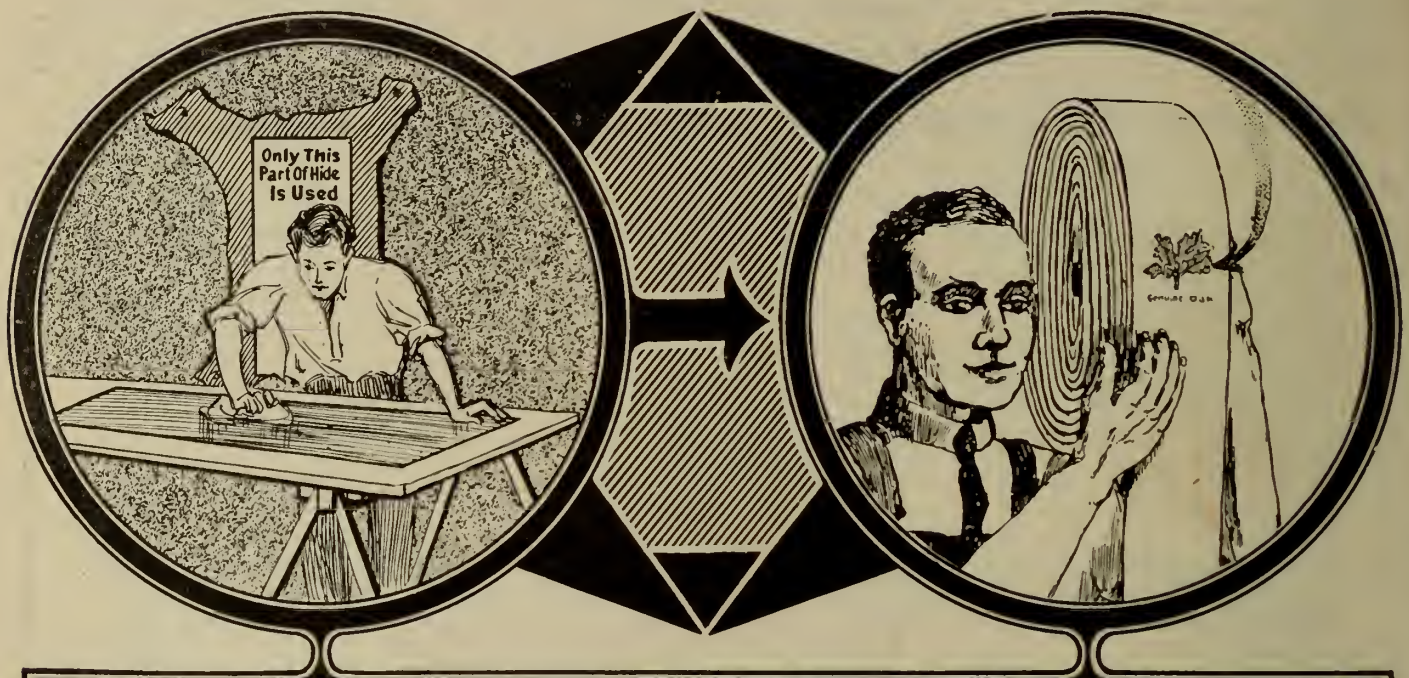
D. K. McLaren's

Genuine British Oak Tanned **Leather Belting**



From Currying to the Finished Belt

--all of the original strength is preserved!

The trouble with a great many beltings on the market to-day is that whatever strength the original hide possessed has been lost during the process of tanning and curing. As a result the finished belt is weak, slips on the pulley and proves a costly item of overhead.

In D. K. McLaren's Leather Belting all the original strength of hide is fully maintained; and only the **best portion** of the hide is used. Every inch of **D. K. McLaren's Leather Belting** represents flawless backs from the hides of the choicest steers.

In order to put this natural strength into a finished belt the BRITISH-OAK-TANNING process is used. This most approved method for preparing belts finishes **D. K. McLaren's Leather Belting** so that it is practically slipless, stretchless and unbreakable.

In spite of this high quality the price is truly economical. A comparison will enable you to judge better. **Write for information, prices and list of many users.**

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

DE LAVAL PUMPS
in
By-Product Plant

THE accompanying photograph shows part of the ammonia recovery plant of the Ford Motor Co.

The centrifugal pumps are all of De Laval manufacture, of capacities of 100 to 1,500 gal. per min. against heads of 65 to 115 ft. Most of them are handling ammonia liquid, while some are handling water.

De Laval pumps were chosen because of their guaranteed efficiency and reliability. All De Laval pumps are interchangeable, as they are manufactured to limit gages. They are also easily accessible for inspection, due to the horizontally split casing, with suction and discharge connections in the lower half of the casing. Parts subject to wear, such as bearings, impellers and labyrinth wearing rings can be renewed quickly and at small expense.

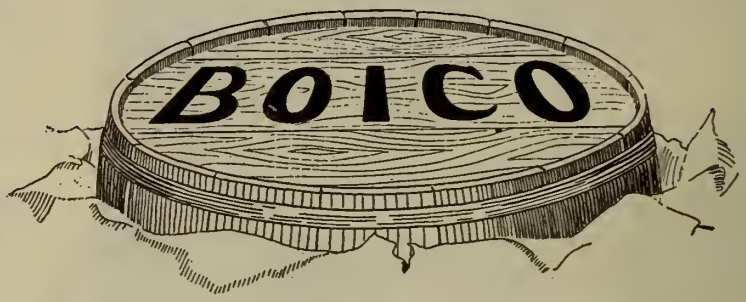
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.



Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

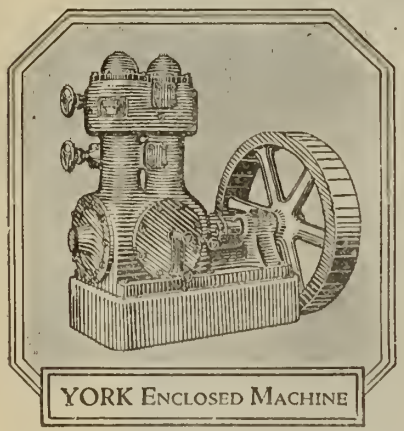
YORK



RELIABLE REFRIGERATION
For Every Practical Purpose

The governing factor in the selection of Refrigerating Equipment, in most cases, is the reliability of the machine. Can it be absolutely depended upon to perform the work? A shut-down during the warm season is always annoying and often is an item of expense, due to loss of production or deterioration of products in storage.

York Refrigerating Machines have demonstrated their absolute reliability by more than thirty-five years of satisfactory service, which has given them a high reputation throughout the refrigerating field.

Ice and Ice Cream Manufacturers, Meat and Produce Dealers, Creameries, Dairies, Confectioners, Grocers and many other industries are using York Mechanical Refrigeration profitably in the production and marketing of high grade products. If you require Refrigeration in your business, we should be pleased to have you investigate the York System.

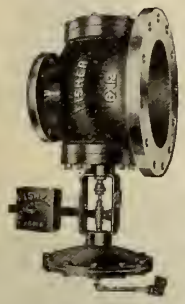
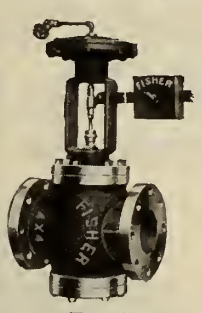
FISHER
TRADE MARK REGISTERED



Type 11—A



Type 10

Simplicity and Reliability

You want your pressure regulators to be simple in construction and reliable in operation.

They must be accurate and so constructed that they will not stick—made of materials that will resist wire-drawing.

Fisher Pressure Regulators

have stood the test of time in service. Engineers have come to find that, once installed, and properly adjusted, they will render continuous, accurate service for unbelievably long periods of time.

TYPES 10 and 10-A are particularly adapted to low pressure service.

Types 11 and 11-A are especially designed for installations where expanded outlet valves are required, such as vacuum heating systems.

TYPE 55 is a spring controlled diaphragm regulator designed for use where the lever and weight type is not suitable.

These steam savers, like all Fisher Specialties, have been faithfully serving Canadian Engineers for many years.

"POWER PLANT SPECIALTIES" is a good book to have in your library. Write for your copy today.

Cutting Coal Costs

For 44 years Murphy Furnaces have been saving coal and lightening labor for thousands of users in every section of the country. Many reports are being received such as this from a City Hospital saying that they saved from seven to ten tons of coal per 24 hours over previous hand fired conditions.

MURPHY AUTOMATIC FURNACES

Here's why the Murphy Furnace is a fuel saver—it feeds the coal without opening the fire doors. The admission of cold air in large volumes is thus prevented; economy is secured and the life of the boilers is prolonged. The Murphy Furnace goes a step further. The fire is cleaned and the refuse removed automatically. This is a continuous operation and can be regulated to meet any condition. Every part of the fire chamber is visible and accessible. There is no periodic dumping nor drawing out of ashes, clinker, and incandescent fuel and coke, with resultant lowering of furnace temperature and steam pressure.

A request from you brings our Catalog HM-11 describing the Murphy Furnace in Full.

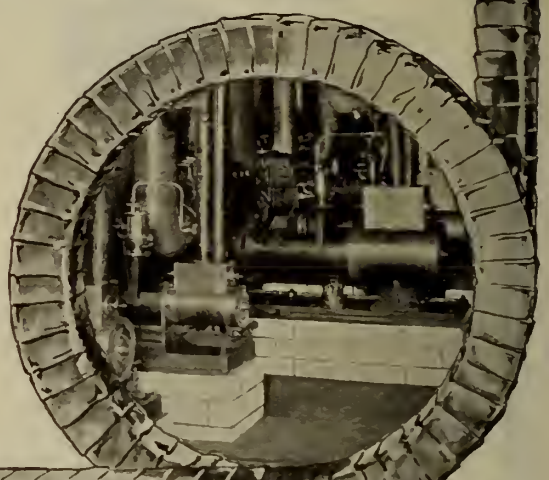
John Crane

Eight Years of Packing Service

JOHN CRANE Flexible Metallic Packing Shows Greatest Results in Constant Service

Eight years ago Chief Engineer, N. Gross, of the Standard Oil Building, Chicago, installed JOHN CRANE Flexible Metallic Packing in the boiler-feed pump pictured below. Mr. Gross reports packing and pump in good order after eight years and has standarized JOHN CRANE on all service.

JOHN CRANE holds this long service record because of its scientific, practical construction. Made of babbitt foil and graphite, it brings Packing science "The Babbitt-bearing Principle," and while responding to the slightest pressure of the gland never dries out, but remains compressible and will not score rods.



Write for your copy of "THE ANSWER" a book that tells unusually interesting things about packing problems.

LUNKENHEIMER
"Ferrenewo" Valves

"FERRENEWO" Valves are *economy* valves, proved so by their record of years in service. Low initial cost, wear resisting materials and the ease of renewal of all the parts should necessity require, makes them highly desirable for piping equipment where the pressure does not exceed 150 pounds.

LUNKENHEIMER "Valve-iron" from which "FERRENEWO" Valve bodies are made is an especially alloyed and processed Ferrous Composition. The renewable *seat ring* and *disc* are made of LUNKENHEIMER "Valve-nickel," while the bonnet, stem and bonnet ring are made of bronze compositions formulated especially for the duty each part performs.

The "FERRENEWO" material combination and unique design, coupled with the LUNKENHEIMER method of manufacture insures successful results under the wide range of operating conditions for which "FERRENEWO" Valves are adapted.

LUNKENHEIMER Distributors situated in every commercial center carry "FERRENEWO" Valves in stock for immediate delivery.

To standardize on "FERRENEWO" Valves is to *economize* in valve cost and maintenance.

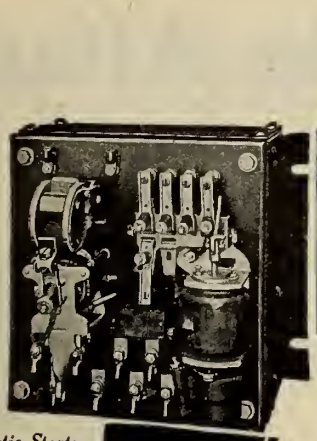
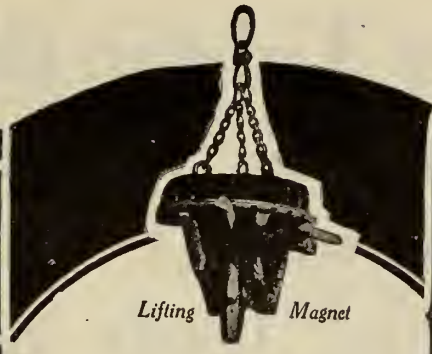
CUTLER-HAMMER



Automatic Starter



Lifting Magnet

Compensator

Magnet and Control Devices

¶ Cutler-Hammer Lifting Magnets and Magnetic Separators have proved of exceptional value in the mining field, in steel mills and in many other industries for lifting and separating metals. The Magnetic Clutch and electrically operated Brake, used primarily in steel and rubber mills and for crane control repectively, are widely applicable to many industries where the gradual engagement or adequate braking of a load is desirable.

¶ In electric controlling devices of all kinds Cutler-Hammer is the recognized standard of dependability, whether for fine speed adjustment of a machine, extremely close voltage regulation, the wonderful light dimming and colour effects in a modern theatre, or the automatic control of heavy loads or other special operations.

¶ Details and recommendations of suitable Cutler-Hammer apparatus for your control problems are available at our branches.

—To enroll all competent engineers in this organization.

—To impart information beneficial to the profession.

Incorporated at Ottawa June, 1917

—To assist members out of employment to obtain the same.

—To procure by legal enactment greater safety in the operation of steam plants.

—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Now is the time—not to-morrow—when you will get the most benefits from membership in the

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

IN THESE testing times the man who makes his mark is the man who devotes a large part of his leisure hours to further improvement in his chosen profession.. The important part that class organizations are doing to forward this expansion can be seen when a survey is made of the large number of associations that have sprung to life in the past few years. The underlying motive of all these associations—greater individual development—is very outstanding in the case of the CANADIAN ASSOCIATION of STATIONARY ENGINEERS. This organization by means of illustrated and non-illustrated lectures, provides its members with all up to the minute progress made in the engineering profession.

A GLANCE at the upper panels will show the important principles of this important organization. They are worthy of serious thought.

Any man interested in an association of this kind and living where less than fifteen engineers reside may send for a copy of our constitution and make application to the nearest lodge for membership. If living where there are more than fifteen engineers it is advisable to get together and send in a written application. The undersigned will be very pleased to give any further information required.

Jones "A-C"

Jones "A-C" Stokers

are automatically cleaned, high-duty stokers. From coal-hopper to ash discharge the cleaning is entirely automatic. No hand labor is needed. No trouble is experienced from big clinkers in the fire—and no clinkers are formed either on the bridge wall or side walls.

As the steam-driven rams push the charges of green coal into the retorts, the entire fuel bed is slowly pushed toward a balanced dump plate at the rear. This is ***not*** a gravity movement. The incline of the retorts is not sufficient to to cause avalanching. By the time the fuel bed reaches the rear of the furnace, the fire is burned out and nothing is deposited on the dump plate but dead ash and refuse. This dump plate is so balanced that it is easily and quickly operated by hand. No power driven dumping mechanism to cause trouble.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. The old-established Jones Under-Feed Stoker Co., Ltd., has recently been reorganized as the Under-Feed Stoker Co., of Canada, Ltd., and the reorganization makes available for Canadian Power users the extensive engineering resources of the Under-Feed Stoker Co. of America.

Jones "STANDARD"

Jones "Standard" Stokers

are very simple. There are no moving parts in the fire—and very few moving parts of any kind. Simplicity and easy accessibility insure low maintenance costs.

Fuel and air supplies for both types of Jones Stokers are controlled automatically, and proportioned for complete combustion and high efficiency with any grade of coal. Smoke is waste—with Jones Stokers there is no waste. The automatic controls can be adjusted to maintain any desired steam pressure within very close limits—regardless of sudden changes in load.

Jones "Standard" Stokers can be installed under limited space conditions. No ash pits or other excavations are necessary. Old boilers can be equipped without changing settings. Wherever installed, they increase fuel efficiency and reduce operating and maintenance costs.

Using Bleeder Steam in Factory Heating

Bleeder Extraction—Elementary Turbine Theory—The Bleeder —Automatic Control of Bleeder Valve — Necessity of Check Valve—Dash Pot on Check Valve—Volume of Steam Extracted —When It Pays to Bleed Steam

By J. A. McGILLIVRAY

OF LATE considerable space has been given to the discussion of the value of exhaust steam for heating purposes. In the October 20th issue of Power House the question was discussed by Mr. Fenner, who demonstrated the benefits of increasing the back pressure on the engine as compared to using a reducing valve to bleed high pressure steam, basing his argument on a heat unit basis, which is the only correct way to approach the subject. I think the readers of Power House will grant that he clearly drove home his argument with respect to this statement, that the heat units (B.T.U.) required by the engine for a given amount of work were the same, regardless of what the back pressure was, and that provided the steam exhausted (all the steam) could be utilized for heating, it was not a loss to increase the engine back pressure for purpose.

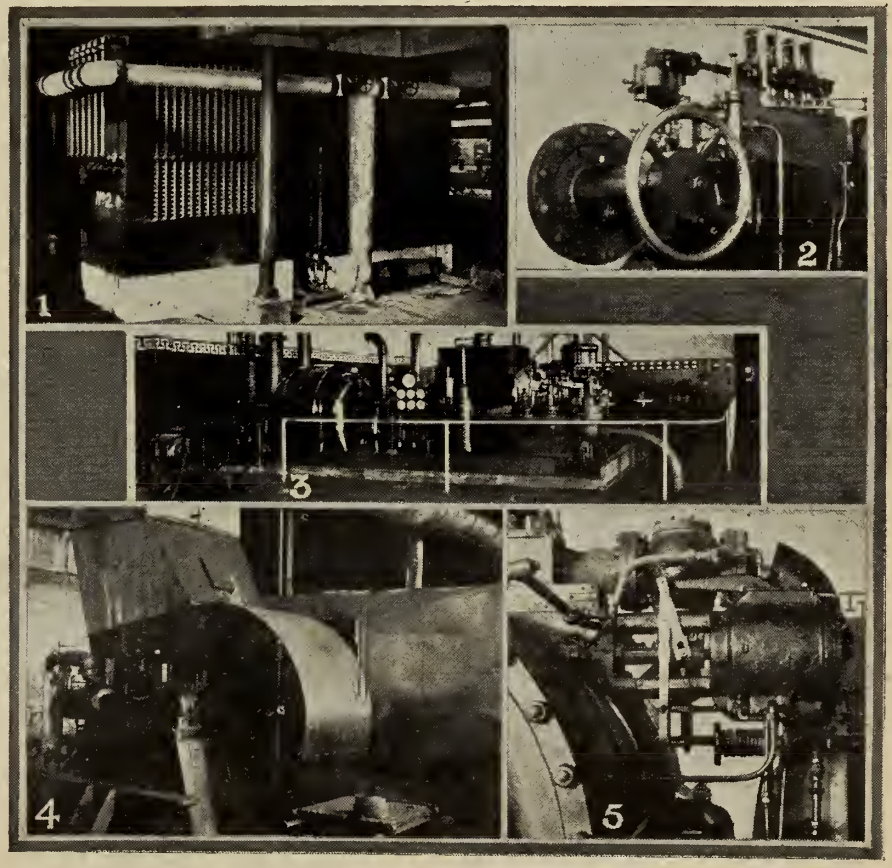
Hitherto the discussion has been mainly confined to utilization of the exhaust from reciprocating steam engines, and rightly so, since non-condensing steam engines are to be found in the majority of plants, where heating is a consideration and have well deserved recognition by right of early establishment in the industrial field. Their simplicity of operation and dependability for many classes of work, makes the reciprocating steam engine as a prime mover, more popular than the turbine, especially in moderate sizes. Nevertheless, the steam turbine is coming to the front, and has a field all its own where it greatly excels the reciprocating engine, and one of the most interesting types is that known as "Bleeder Type."

Bleeder Extraction

The Bleeder Type is especially furnished where low pressure steam is required for heating purposes, such as process work, or factory heating, in combination with Electric motive power. Bleeder Types are designed for a variety of conditions of operation, both in condensing and non-condensing units, or any combination of the two.

Fig. 1. shows a Westinghouse Parsons bleeder type designed to operate non-condensing in a sugar refining plant, where two different pressures were required for process work as well as electric generation. The turbine exhausts into the low pressure line at 8 lbs. gauge (23 lbs. abs.) and at the same time bleeder steam is extracted from the 1st stage at 45 lbs. gauge (60 lb. abs.) using steam at the throttle at 160 lbs. gauge. The volume of steam that can be extracted from a steam turbine is, of course, a function of the load. (This feature will be described later in this article).

The method of steam extraction from between the stages of a turbine depends on the class of service the steam is used for, and whether the generator load is steady or variable. If the generator load is fairly constant and the amount of steam required is constant (within the capacity of the turbine) the extraction is obtained by manually adjusting the extraction valve to deliver the predetermined amount of steam, but if the generator load is variable this will be unsatisfactory since an increasing load will cause the governor to admit more steam to the first stage, the bleeder ports being adjusted to let a constant volume flow to the second stage. The increased volume admitted to the first stage must



1.— Vento Cast Iron Heaters. 2.— Valve Gear and Mixed Pressure Turbine. 3.— Westinghouse Non-condensing Bleeder Turbine. 4.— 84 inch Sirocco Fan. 5.— Curtis Automatic Extractor Gear.

pass to the bleeder line. The first stage wheel takes the swing of the load, the bleeder line pressure varying accordingly. To overcome this disadvantage an automatic extraction device is used, a modification of which is shown in Fig. II.

In order to understand the effect of extracting steam from between the stages of a turbine we should know something about the elementary theory of steam turbines.

Turbine Theory

The statement is sometimes set forth that all the kinetic energy of the steam is absorbed by the wheel of the first stage, and the steam then extracted for heating, retaining all its heat. This is an exaggeration, pure and simple, since if the wheel does any work at all it is at the expense of heat.

Let W= Wt. of steam in lbs. per sec.

Let E =energy given up by one lb of steam in ft. lbs.

Let P_1=initial pressure lbs. per sq. in. (abs.)

Let Pn=final pressure lbs. per sq. in. (abs.)

Let H_1=heat content per lb. at the initial pressure.

Let Hn=final heat content per lb. (at last stage pressure).

The heat available for doing useful work is W (H1 - Hn)=B.T.U. available

If the steam expands against a resistance, as for example, an engine piston, the energy given up in forcing the piston forward may be expressed E_1=778 w (H1-Hn)=Ft. lbs.

If the steam expands within a perfect nozzle the energy will be given up in imparting velocity to the steam itself.

Thus $E=W\left(\frac{V^2}{2g}\right)$=ft. lbs. in which

V= velocity in ft. per second.

If the velocity (V) is retarded to (v) ft. per second

$$E=\frac{W(V^2-v^2)}{2g}=\text{ft. lbs. per second.}$$

If all the energy was absorbed by the wheel ignoring all losses, the final velocity (v) would be O, since the energy E is completely absorbed, it follows that the velocity becomes zero.

$$\text{Then } E=\frac{W(V^2-v^2)}{2g}=\frac{W(V^2-O)}{2g}=\frac{WV^2}{2g}$$

Now then

$$E=\frac{WV^2}{2g.}=778W\ (H_1-Hn)$$

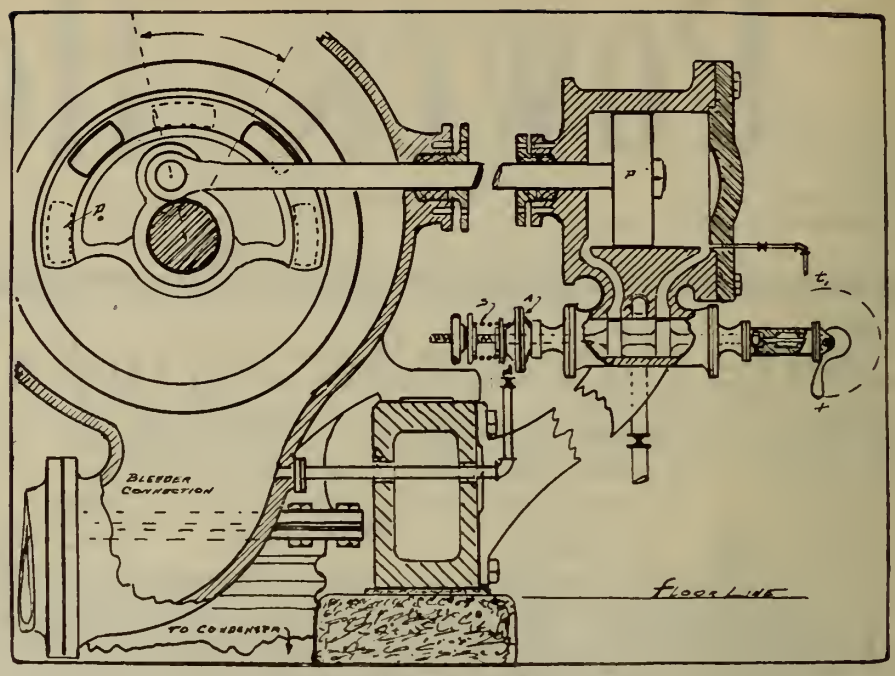
Combining and transposing

$$V^2=(HI-Hn)\ 778 \times 2g.$$

And $V=\sqrt{(H_1-Hn)\ 778x2x32.16}=V\ 224\sqrt{(H_1-Hn)}$. If there are (N) pressure stages.

$$V=224\sqrt{\frac{(H_1-Hn).}{N}}$$

From the foregoing it can be seen that the energy varies as the square of the velocity, and directly with the heat drop,



Showing Automatic Extraction Gear.

or, if the wt. = 1 lb., E=(H-Hn) 778,

also $E=\frac{V^2}{2g.}=\frac{V^2-v^2}{2g.}$

This is where the error is made by those who state that all the energy of the steam is given up to the first stage wheel.

Let us take an example as follows: Assume a two stage turbine where the entrance velocity to 1st stage is (V) and the exit velocity from that stage is (v)=O. That is, the steam has no velocity leaving the 1st stage wheel until expanded in the 2nd stage nozzles, and the total heat drop between the 1st stage nozzles and the condenser is (H-Hn.)

The heat drop per stage is $\frac{(H-Hn)}{2}$ and the velocity V represents only ½ the energy of the steam, instead of the total amount, yet the equation is correct as it stands.

$$E=W\left(\frac{V^2-v^2}{2g}\right)=W\left(\frac{V^2-O}{2g}\right)=\frac{WV^2.}{2g}$$

But also equals (H-Hn) 778.

Consequently if the turbine was a four stage machine the energy per stage would be 778 $\left(\frac{H_1-Hn}{4}\right)$ and assuming that steam was bled from between the 3rd and 4th stages, it would be quite correct to assume that ¾ of the available energy for doing work in the turbine was absorbed by the three preceding wheels (assuming, of course, ideal conditions; the actual performance of steam turbines is about 80% of the ideal), while the heat content corresponding to the bleeder pressure is available for heating, plus whatever superheating may be present in the bleeder stage.

The Bleeder

Let us consider a case in point. Where steam is to be bled from between the stages of a two stage condensing steam turbine, using steam at the initial pressure of 175 lbs, gauge, and a condenser pressure of 1 lb. absolute. The bleeder pressure is to be 5 lbs. gauge.

According to the elementary theory of the turbine the pressure between the stages will be that corresponding to the heat drop, or $\frac{H_1-Hn}{2}$ for a two stage machine. The total heat drop from the initial to the condenser is

(H' - Hn)=1198.5=1104.4=94 B.T.U.

and the heat drop per stage $=\frac{94.1}{2}$

= 47.05 B.T.U.

The corresponding pressure for the heat drop of 47.1 B.T.U., or (1198.5—47.05) = 1151.45, and the 1st stage pressure is 1 lb gauge. Since we are to bleed steam at 5 lbs. it is clear that something must be done to increase the 1st stage pressure to 5 lbs. and the simplest way to accomplish this is to choke off the steam on its way to the 2nd stage, hence the extraction device shown in Fig. 3.

The stage pressure will vary with the turbine load and is less than atmospheric pressure at partial loads, and in actual condensing turbines does not usually exceed atmospheric pressure in the 1st stage even at full load. Since the stage pressure is constantly varying with the swing of the load it is evident that any certain setting of the bleeder valve will be unsatisfactory the moment the load changes. If, for instance, the ports leading to the second stage are half closed in order to maintain 5 lbs. pressure in the 1st stage, when the turbine load is 50%, an increase in the load must be carried by the 1st stage wheel, so long as the admission to the second stage is constant, the result will be an increase of pressure in the 1st stage, due to increased volume of steam admitted, a con-

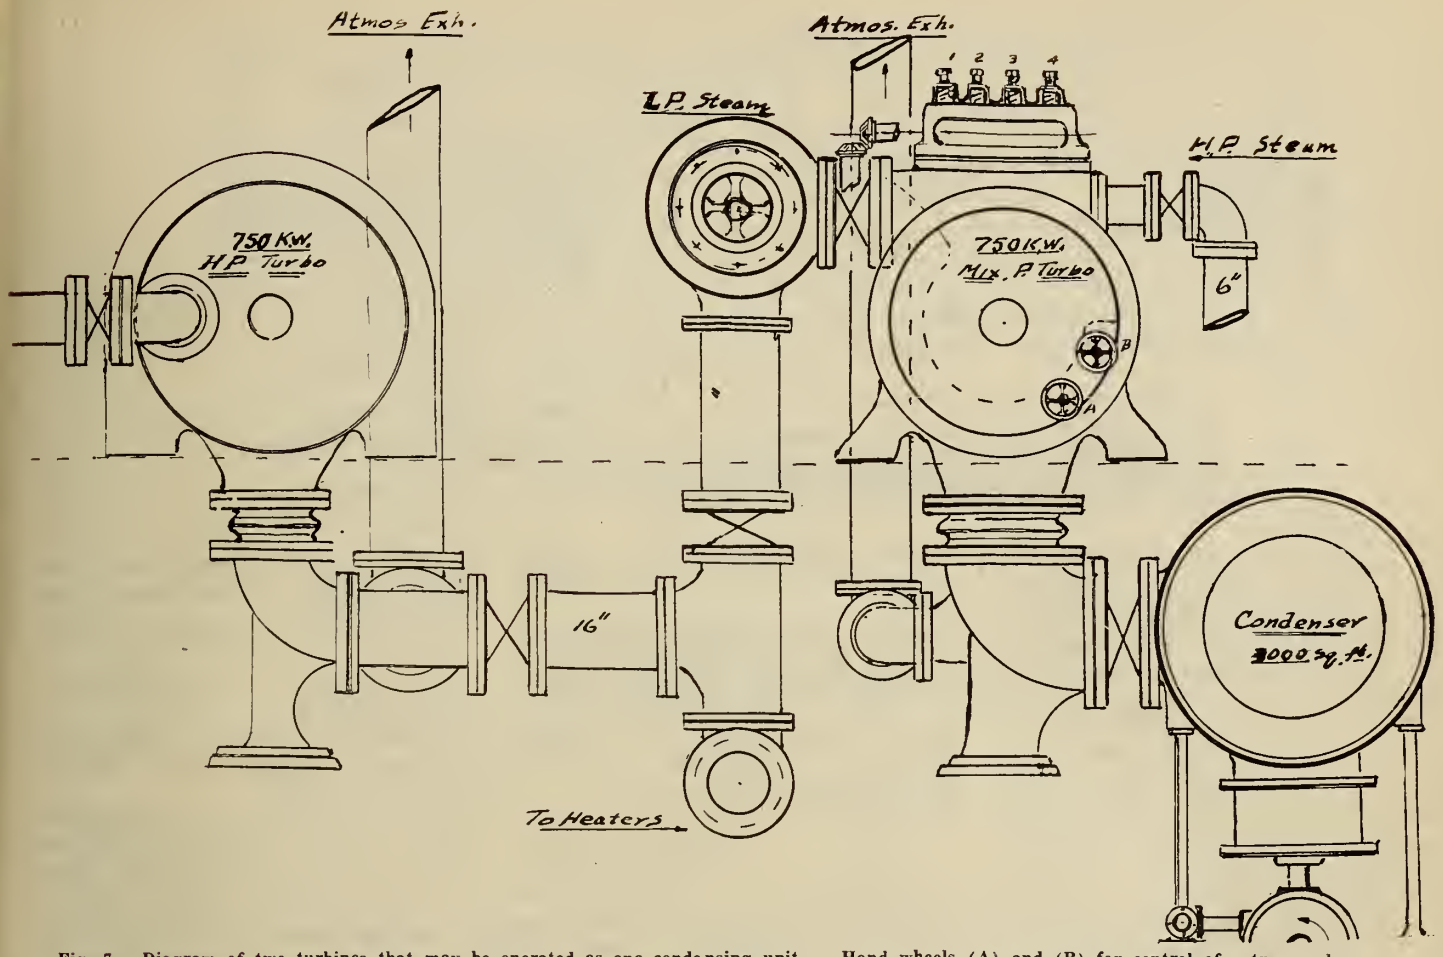


Fig. 7 — Diagram of two turbines that may be operated as one condensing unit. Hand wheels (A) and (B) for control of extra nozzles increasing or decreasing the h.p. steam as conditions warrant. For actual layout of piping see Fig. 6.

sequent corresponding lowering of the efficiency of the 1st stage wheel and an increase of pressure in the bleeder line, while a diminution of the load produces opposite effects. It is now evident that the extraction valve must be automatic in order to maintain constant stage pressure, with varying loads. That is, the opening to the last stage nozzles must be automatically adjusted. Where the load is fairly constant, the extraction valve may be manually adjusted.

Automatic Control of Bleeder Valve

Referring to Fig. 2, which is an exaggeration of the automatic extraction device. The position of the piston valve which covers the ports of the extraction cylinder is determined by the pressure, in the bleeder stage, as follows: When the pressure builds up, it acts on diaphragm (A), causing the valve to move to the left, admitting steam to the left side of the main piston (P) which travels to the right, opening the ports to the second stage. When the pressure falls off in the bleeder line the operation is reversed. The bleeder pressure is determined by the tension on spring (S) which oppose the diaphragm. When the bleeder pressure times the diaphragm area equals the spring tension, the valve remains stationary.

When the extraction device is not in use the cam (t) is turned into position tl, which forces the valve to the left, causing the piston to travel to the right, where it remains, the ports (P) being thus opened. To prevent overtravel of the piston, there is an arrangement of floating levers as shown in Fig. 3, which is a cut of the Curtis Extraction device. An absolute essential in all turbine bleeder systems is the provision of a suitable check valve between the bleeder outlet and the system into which the steam is bled, to prevent the possibility of the steam from the heating system or other source, backing up into the 1st stage of the turbine and driving it as a mixed pressure machine, driving it to destruction should the turbine be lightly loaded. The writer has had the greatest difficulty in trying to make some operators understand how the turbine could be driven to pieces by low pressure steam through the bleeder connection and a few words on this point may not be out of place.

Necessity of Check Valve

Assume a turbine having a bleeder connection between the stages, and no check valve in the line. The bleeder being connected to the same system into which a number of reciprocating units are exhausting, the pressure being at, or near, atmosphere. The admission of live steam to the turbine being controlled by the governor of the high pressure inlet. Should the load be light the governor closes the high pressure admission valves, but the steam is entering the 1st stage through the bleeder, at a pressure which is equal to or greater than the normal 1st stage pressure at full load. There being no governor control on the bleeder line, the speed of the machine keeps on increasing even after the turbine governor has closed the live steam valves. The machine is now running entirely without control so long as the low pressure supply holds out. The speed is continually increasing until the emergency trips the main throttle valve, still the speed increases, since both the turbine governor and emergency are useless as far as any further control are concerned, and the only way to stop the turbine is to shut off the bleeder, but by the time the attendant realized that the machine was running away it might be too late to prevent its destruction.

In some installations there is a governor provided in the bleeder line as well as the high pressure inlet and the turbine can be operated as a mixed pressure machine, when conditions warrant, but those are special cases.

Dash Pot on Check Valve

The check valve in the bleeder must be provided with a good dash pot, that will absolutely prevent slamming, since the pressure is not steady in the bleeder system as a rule. The slamming of the check valve is aggravated by the pulsations of the exhaust of the reciprocating engines, when there are such, exhausting into the system.

Volume of Steam Extracted

It does not follow that when the pres-

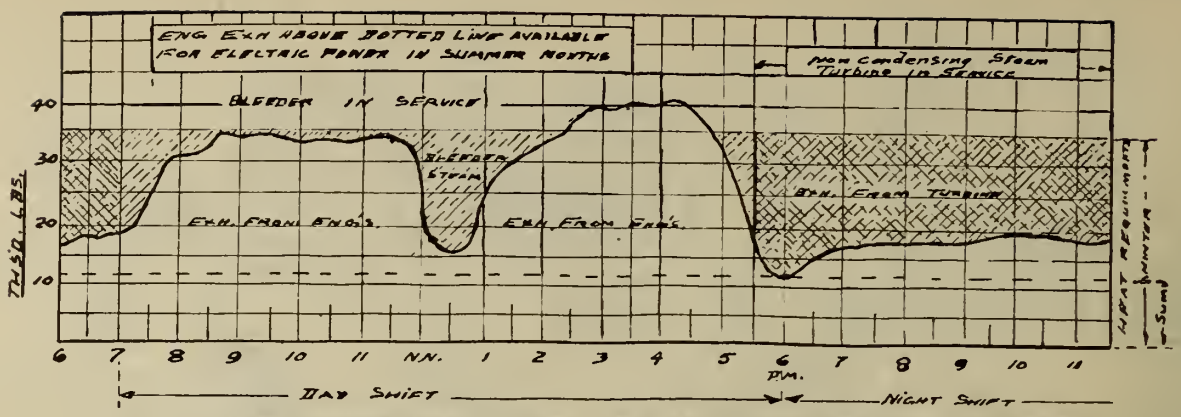

Fig. 4 — Chart showing actual average conditions in a 25 car plant using steam for drying of lumber and shop heating, operating at capacity in day time and 45 per cent. capacity night time. Note that the day work is at a maximum between 2:30 and 4:30 P.M. In summer months all the exhaust steam over the requirements of feed heater and dry kilns is used in the mixed pressure turbine for Electric power generation.

sure in the bleeder stage is constant that the volume of steam bled is constant. The volume of steam entering the turbine through the admission valves is a function of the load on the machine at that instant, as truly as though the bleeder did not exist, and the volume is constant, only so long as the load remains so, and is a maximum when the load is such that the 1st stage is doing all the work it can do at normal speed, with the ports to the 2nd stage entirely closed by the extraction device. That is all the steam admitted to the turbine is being bled to the heating system or low pressure system. The turbine is running as a single stage non-condensing machine except that by reason of the condenser, the 2nd stage wheel is revolving in a vacuum. Continuous operation under such conditions would not be justified, since it is very questionable if the benefits of the vacuum in the last stage would justify the operation of the auxiliaries, even if trimmed down to the lowest practical speed. However, such conditions exist for very short periods, if at all, in actual practice. The advantages or disadvantages of bleeding steam from a turbine lay entirely in the conditions existant where such operation is, or seems to be justified, and require special attention and advice from the builders of such types, who are always pleased to give the intending purchaser the benefit of their experience.

We will assume for convenience certain conditions of bleeder operation and discuss the question in such a way that it may be helpful to the man who has a bleeder turbine and who does not really know whether it is a good thing or not, or who does not know when it should be run as a "bleeder," "straight condensing" or "non-condensing."

When It Pays to Bleed Steam

Assume a 1000 K.W. two stage condensing steam turbine of the bleeder type, capable of carrying full load (1000 K.W.) when running non-condensing, using 16 lbs. of steam per K.W.H. at full load, and 23 lbs per K.W.H. non-condensing, assuming that the efficiency does not fall off much at ½ load, the consumption of steam per K.W.H. to be assumed for convenience at those figures for any load in excess of 50% capacity.

Let the load be variable between ½ load and full load, with the average about 75% capacity. The average steam

$$\text{cons. per hour} = \left(\frac{16 \times 1000 \times 17}{100}\right) = 12{,}000$$

lbs. per hour condensing, and

$$\left(\frac{23 \times 10000 \times 75}{100}\right) = 17{,}250 \text{ lbs. per hour}$$

non-condensing. If the requirements of the heating system are, say, 10,000 lbs. per hour at atmospheric pressure, by using the bleeder 10,000 lbs, go to the heating system and X lbs to the condenser.

The 10,000 lbs. bled is doing work at the non-condensing rate of 23 lbs. per K.W.H. and represents $\left(\frac{10000}{23}\right)$ of 750 K.W.H. = 435 K.W. The balance of the work is done at the straight condensing rate of 16 lbs. per K.W.H. and the total steam consumption is (10000+(750-435)) x 16=(10,000+ 5040)=15045 lbs. per hr.

$$= \frac{15045}{750} = 20.6 \text{ lbs. per K.W.H.,}$$

which is a saving at the turbine alone of 12.8% in steam consumption over non-condensing operation. Next assume that we desire to run straight condensing and bleed, the equivalent of the bleeder steam, from the high pressure line, where do we stand? Whatever steam is bled through the reducing valve will have to be charged up to the turbine operation for comparison.

Then

to—straight condensing operation 750 K.W.H. @ 16 lbs=12000 lbs per hr.

to—heating system $\frac{10000 \times (1150 \text{ B.T.U.})}{(1197.3 \text{ B.T.U.})}$

=9,600 lbs per hour

Total chargeable to condensing operation 21,600 lbs per hour.

$$= \frac{21600}{750} = 28.8 \text{ lbs. per K.W.H.}$$

It works back to the turbine operation as follows, for the three different methods, in the order of their economy, they are:

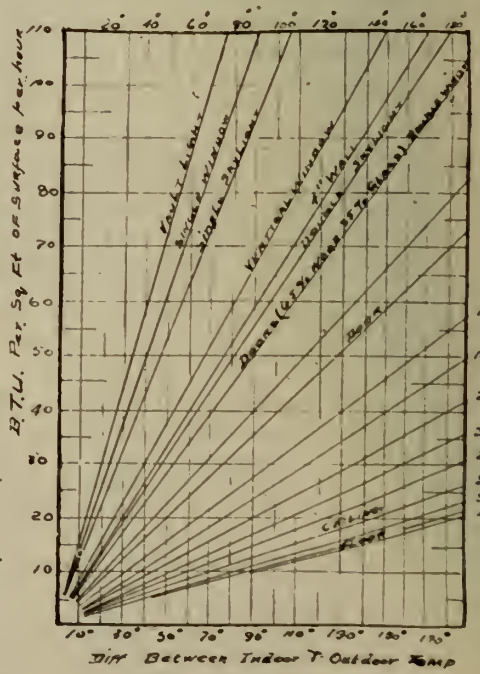
Bleeding operation 20.6 lbs. per K.W.H. =100%.

Non-condensing operation, 23 lbs. per K.W.H.=112%.

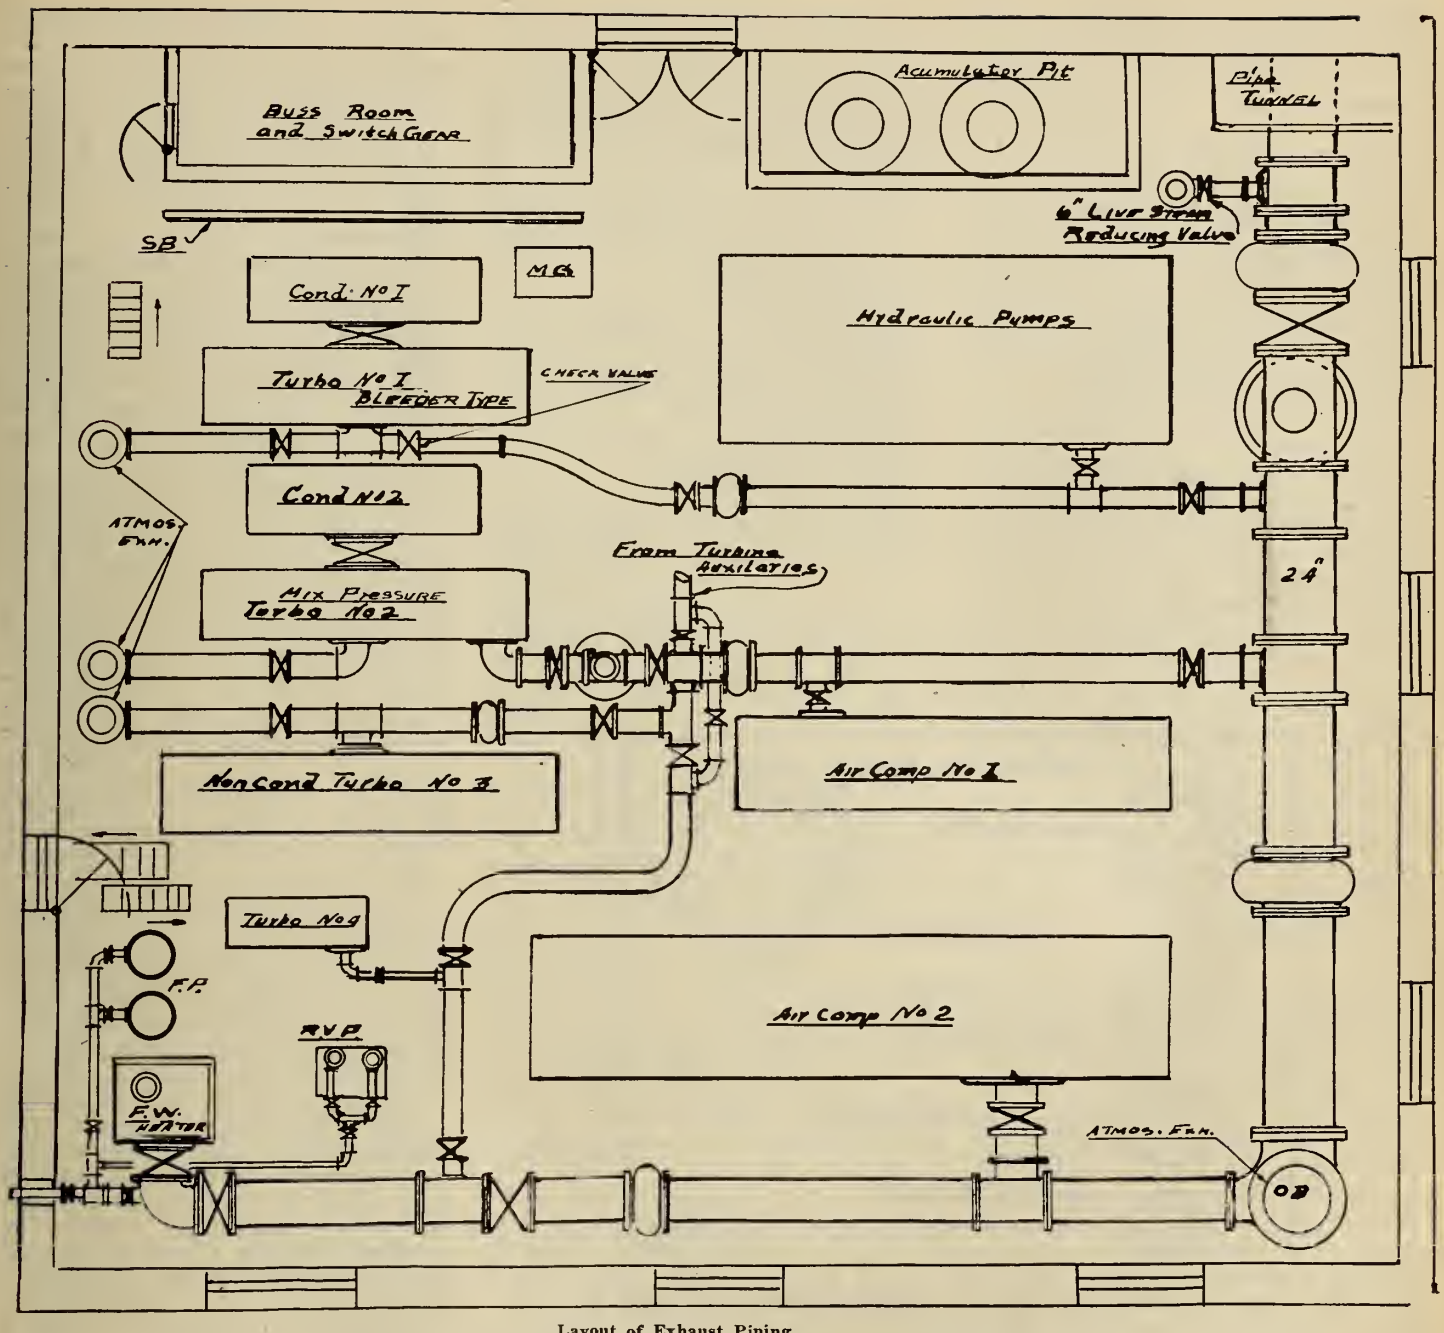
Straight condensing and bleeding from the main for heating system, 28.8 lbs. per K.W.H.=140%.

It can be seen that what would appeal to the average observer as the best method is the most extravagant. Bleeding steam from the turbine under the above conditions is 12% more economical than non-condensing operation and 40% more economical than straight condensing.

The foregoing demonstrates that when the requirements for heating exceed or are equal to the consumption of the turbine when run non-condensing, that it pays to run straight non-condensing, When the requirements are less than non-condensing steam consumption, use the bleeder. Even for small quantities it will pay to bleed steam, provided the



Showing Heat Transference.



Layout of Exhaust Piping.

bleeder pressure is not far from atmospheric pressure.

Effect on Efficiency When Bleeding Steam

It will be argued by the engineer at first that the fact of the bleeder (even if not bleeding steam or at least large amounts) being in service greatly reduces the turbine efficiency. That is, that the drop of efficiency will offset the benefits accruing from bleeder steam. Well, let us see what that argument amounts to.

So long as the steam is taken from the 1st stage, without doing any work in the 2nd stage, there is a falling off of about 45% in the efficiency of the turbine, but if the stage pressure is increased and no steam bled, but is admitted to the next stage at a higher pressure and expanded to the condenser pressure the efficiency of the 1st stage is less, but that of the next is greater. This statement is not absolutely correct in practice, but is theoretically correct and is sufficiently correct in practice to refute the argument.

Referring again to the elementary theory of the steam turbine as set forth elsewhere, we shall demonstrate that theoretically there is no drop in the overall efficiency of the turbine when the 1st stage pressure is increased, the total heat drop to be the same.

First:—A two stage or multi-stage turbine working between the limits of 175 lbs gauge, and 2 lbs. absolute the work is proportional to the heat drop, and the work per stage (theoretically) proportional to the heat drop per stage.

For the conditions of the 1st case $E=(H_1 - Hn)\ W \times 778$ for convenience assume 1 lb. of steam, then total work $E=(H_1 - Hn)\ 778 = (1197.3—1115)\times 778 = 64029.4$ ft. lbs. The work per stage $= \left(\frac{64029.4}{2}\right) = 32014.7$ ft. lbs. and the corresponding 1st stage pressure is 5 lbs. gauge (in practice it is less) say that the normal 1st stage pressure is zero gauge pressure, the drop in the 1st stage will be 46.9 B.T.U. and 36 B.T.U. in last or 2nd stage.

Second:—The same machine working between the same limits of pressure except that the 1st stage pressure is increased to 5 lbs. gauge

E per stage = heat drop per stage = (1197.3—1156.2) = 41.1 B.T.U. in the 1st stage and (1156.2—1115)—41.2 B.T.U. in the last and the total work = 82.3x778 = 64,029 ft. lbs., the total work is the same in both cases, but the 1st stage efficiency is reduced 13½%, while the 2nd stage is increased 13½%.

The expression $E=(H_1—Hn)\ 778$ is not quite correct when referring to the

steam turbine since the energy of the steam is given up in imparting velocity to the steam itself, and the expression $W(V^2)$ becomes $E=\frac{}{2g}$, but since the work is proportional to the heat drop there is nothing wrong with the statement.

Working it out the other way we must first find the velocity of the jet which varies as the square root of the B.T.U.

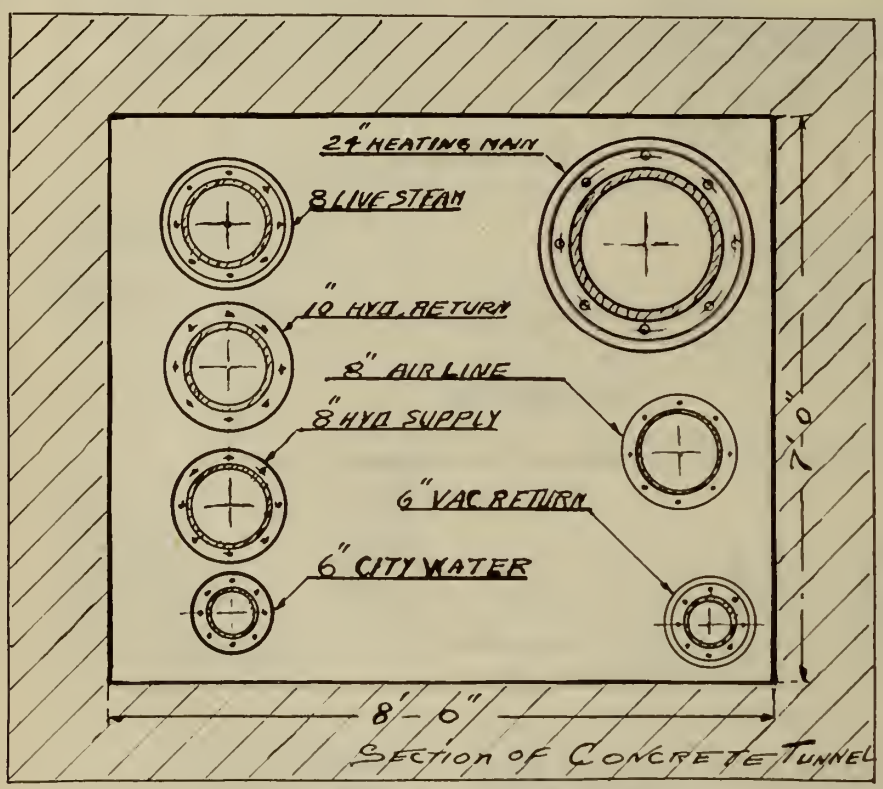
Then $V=224\sqrt{(H_1-H_n)} = 224\sqrt{82.3}$. or heat drop.

$V=(224 \times 9.07) = 2032$ ft, per second.

If the quantity considered is one lb. per second the energy available

$=(\frac{1 \times 2032^2}{2 \times 32.16})=64{,}195$ ft. lbs. per second.

I think I have shown that, theoretically at least, the argument that the turbine efficiency as a whole is reduced by increasing the 1st stage pressure is unfounded, as long as this is done within reasonable limits.



Showing Section of Concrete Tunnel.

I would like to suggest to the readers of Power House who have bleeder turbines, but who do not use the bleeder, because it is found that the exhaust steam from the reciprocating units just about maintain sufficient heat, in the plant, but who may be troubled with varying conditions affecting the steam consumption of the engines in such a way that the heating system pressure is fluctuating, sometimes between wide limits something like Fig. 4. The bleeder could be used to flatten the humps and fill the holes in the curve, giving ideal heating conditions, represented by a straight or flat curve. I think I have demonstrated that the fact of leaving the bleeder in service for just such purposes has not the bad effect on the turbine economy generally supposed, provided the turbine is designed for bleeding.

Now that we have had a discussion of the bleeder turbine I will pass on to a brief description of a heating plant where bleeder turbines form part of the equipment.

The heating requirements of the plant in question are in the winter months about as follows:

Ave. winter months—	
Dry kiln for lumber drying ave. ....=	14,000 lbs. per hr.
Shop heating (main plant) 1100'x500' =	16,000 lbs. per hr.
Hot blast vento system vac. returns	
Outbuildings, offices etc., inc. foundry offices, valve houses, etc..... ....=	8,000 lbs. per hr.
Feed water heating....=	6,000 lbs per hr.
	44,00 lbs. per hr.

To supply this amount of steam the available exhaust from the reciprocating units is

Day time—	
Auxiliaries.. ....=	3,000 lbs. per hr.
Compressors ....=	18,000 lbs. per hr.
Pumps.... ....=	8,000 lbs. per hr.
Fan engines ....=	2,400 lbs. per hr.
Hammers, etc. ....=	4,000 lbs. per hr. (about)
	35,400 lbs. per hr.

Due to the great length of the lines and the corresponding chances for loss, the exhaust supply does not really amount to more than approx. 30,000 lbs. per hour, leaving a deficiency of 14,000 lbs. to be made up by bleeding steam from the turbines, or from the high pressure main.

The supply of exhaust steam is somewhat variable, especially that from the pumps and compressors. While the pressure on the heating system must be kept fairly constant, owing to the extensive use of thermostatic traps in use at many points and the urgent necessity of maintaining constant temperature in the dry kilns.

The pressure carried on the heating main is 2½ lbs. approx. The returns being connected to a vacuum return system, in which a vacuum of 2" to 3" is maintained. The efficiency of a vacuum return system can be understood when it has been demonstrated in this plant, that steam at ½ lb. gauge can be circulated through 7 miles of 1¼ inch pipe, in an almost horizontal run.

In the day time the bleeder is used to fill the deficiency of the amount of exhaust steam, but in the night time there is only about 45% of the work going on and the available exhaust is depleted to that extent, which leaves a shortage of about 25,000 lbs. per hour. This amount cannot be supplied from the bleeder, since the turbine "night load" is so light that it is out of the question to depend on the bleeder, so at night the turbine is operated non-condensing, exhausting into the heating main, and any further shortage made up from the live steam line through a reducing valve.

There are short periods throughout the day, "when the bleeder supply plus all the available exhaust is insufficient for heating," when the live steam is brought into play. Fig. 5 shows the approximate conditions of load during the day run. The available exhaust steam varies almost directly as the load, "the load on all the units varying alike." It can be seen that the maximum supply is available during the hours when the outside temperature is highest, and diminishes toward evening when the outside temperature is falling off, during those periods it is the duty of the heating system attendant to endeavor to concentrate the heat on the points most requiring it, and to see that all doors are closed. Every artifice is resorted to until the exhaust steam supply is again a maximum.

The opening of doors is the most serious detriment and explains the large amount of steam required for shop heating. The doors must be opened frequently to permit the movement of trains of cars in and out of the shop.

The live steam reducing valve comes automatically into service when the pressure falls off in the heating system. The bleeder maintains the pressure at ½ lbs. up to the bleeder capacity, which, of course, depends upon the load on the turbine, when the pressure in the heating system falls off to about 2 lbs, the live steam reducing valve goes into operation. The reason for the difference in the setting, or adjustment, of the bleeder and the live steam reducing valve, brings out another interesting point.

Lag of Reducing Value

Should the live steam reducing valve be set at 2½ lbs. and the bleeder ad-

justed for the same pressure, the supply would be furnished by the live steam line up to the full capacity of the reducing valve. At the same time the bleeder turbine would furnish no steam, but would be operating with 2½ lbs. pressure in the 1st stage. That is when the reducing valve is between the bleeder and the heating system "as is often the case," there is no drop of pressure from the bleeder to the point at which the reducing valve is maintaining a given pressure corresponding to the bleeder adjustment, and consequently no flow. This fact must be remembered when using a combination consisting of bleeder, turbine and live steam turbine valves.

Exhaust Piping

A diagram of the exhaust piping and valves is shown in Figs. 6 and 7. It will be noted that many combinations are possible in this plant, the most interesting of which is the operation of two separate turbines as one unit, if desired. A test made on the combination of the Westinghouse and mixed pressure operating as a single unit, with the live steam throttle of the mixed pressure tight, showed surprisingly good economy.

The combination was not thought out by the plant designer but is the result of circumstances arising out of the difficulty of securing equipment during the war. At the time when more electric power was required it was impossible to get delivery on new equipment at short notice Cost being a secondary consideration at that time, it was decided to purchase the Westinghouse machine, and run it straight non-condensing if necessary, until such time as a condenser could be installed, but the results of the present combination were so satisfactory that the condenser part of the proposition was set aside. The combination will operate as a 1500 K.W. unit with a steam consumption of about 17 lbs. per K.W.H. at full load, and by the addition of another row of buckets on the rotor of the Westinghouse, "for which provision is made," the combination can be made more economical yet, if desired. However as the exhaust steam requirements for heating in winter months are in excess of the supply from the reciprocating units the arrangements are quite satisfactory for the present. In the summer months the surplus exhaust steam is used by the mixed pressure machine, which is operated on day service for about seven months in the year.

The apparatus for the heating system consists of the following:

"Dry kilns"—one of which is shown in Fig. 8, are heated by 1¼" pipe coils, of which there are approximately seven miles, representing a heating surface of $\left(\frac{7 \times 5280}{3}\right) = 12{,}320$ sq. ft., maintaining a constant temperature of 160 deg. Fah. in the kilns. The condensation is returned to the feed water heater by a return vacuum pump.

"Shop Heaters" consist of Vento C. I. heaters two stacks high and six sections deep in groups of two (8 heaters in all) one of the groups shown in Fig. 8. The supply connections to the heaters are 7" diameter. The riser shown in Fig 8 is 10" with 7" branches to each heater. The air is drawn through the heaters by an 84" Sirocco fan 100 R.P.M. driven by a 12" x 12" Rob. engine (see Fig. 9.) The exhaust from the engine is delivered to the heating system.

The air flows through the heaters at approximately 1200 ft. per minute, producing a heat transference of about 12 B.T.U. per sq. ft. of heating surface per degree difference of temperature Each heater consists of approximately 1680 sq. ft. of heating surface, there being 8 heaters in all maintaining a temperature of about 65 deg. in the shop, at an average condensation rate of nearly 21,000,000 B.T.U. per hour. The size of the shop thus heated is 1100 ft. long by 500 ft. wide, with concrete walls, no floors and wood roof. The exposure to the weather is approximately 650,000 sq. ft. of surface, a great deal of which is glass and doors, the latter left open a lot of the time. The temperature in the shop is regulated by varying the speed of the fans, which varies the rate of heat transference at the heaters.

The condensation from the whole system is returned to the feed water heater at a temperature of about 180 degrees Fah. The return at the vacuum pump are approximately 200 degrees Fah. A spray pipe in the last section of the return line condenses the vapor. The spray water is, of course, mingled with the returns to heater.

The chart Fig. 9 shows the heat transmitted per hour through various substances. While rather unsatisfactory for shop heating problems of the class where numerous doors are opened and left open it is nevertheless instructive. The chart was prepared by Mr. R. Wolfe, M.E., of New York. From a study of the chart it would appear that 40 B.T.U. per hour per sq ft. of building wall when the outside temperature is 70 degrees is very conservative, for most large shops and for shops such as the one of which I write, the requirements will not fall far short of 60 B.T.U. per sq. ft. of exposed surface per hour at times, for instance, the average in this shop required for heating during at least four months of the year is approximately 21,000,000 B.T.U. per hour, with the maximum at about 32,000.000. There are about 650,000 sq. ft.. of outside wall, including roof, but no floor, and $\frac{32{,}000{,}000}{650{,}000} = 49$ B.T.U. per hour based on exposed surface to maintain 65 degrees in zero weather.

Troubles Encountered

Every extensive heating system has some few minor drawbacks peculiar to itself, and require special attention. The most common in large systems, the return vacuum type, is short circuiting of the system. This is partially remedied by the use of thermostatic traps, but the trouble has not been entirely eliminated, due, of course, to the difficulty of keeping the traps in proper order and the presence of scale and dirt which collects in an extensive system, and this is one of the greatest difficulties encountered in the operation of the system which is described here.

INDUSTRIAL RESPIRATORS

Before the war, respirators specially designed for use in industry were, practically speaking, non-existent. Experience with respirators as protection against poison gas during the war, however, has been turned to good account from the industrial point of view and Dr. Leonard Levy, at a recent meeting of the London Section of the Society of Chemical Industry, gave an account of latest developments that have been made in the face-piece of respirators over the type used in the Army, but the canisters employed are unused small box respirator canisters of the type used in the Army, which it has been found difficult to improve upon, and, moreover, they happen to be readily obtainable in large quantities. The fillings of the canisters, however, are quite different from the Army fillings. For industrial purposes, there are now ammonia respirators, which find extensive application in cold storage plant, and for which the most satisfactory absorbent has been found to be crystalline copper sulphate.

The next type gives protection against neutral vapors, such as hydrocarbon fumes in oil fields, cleaning out oil tanks, etc., and here the best results have been obtained with a filling of highly activated vegetable charcoal. A third type is designed to deal with acid gases, such as hydrochloric acid, chlorine, sulphuretted hydrogen, phosgene, sulphur dioxide, nitrous fumes, hydrocyanic acid, etc., and in this case it has been found that a uniform mixture of alkaline granules and charcoal has the longest life. The alkaline granules made use of by the author are slaked lime, diatomaceous earth, ferric hydroxide, and activated charcoal. Finally, there is the carbon monoxide respirator, which has presented many novel problems, because there is no known absorbent suitable for use in a respirator canister for the removal by chemical absorption of carbon monoxide. A thoroughly effective method ed with this gas. An effective method, however, is by the catalytic oxidation of the carbon monoxide by the oxygen of the atmosphere, using certain special mixtures of oxide, such as finely divided manganese dioxide, copper oxide, cobalt oxide and silver oxide. Moreover, as carbon monoxide gives no indication of its presence, it is necessary for a detector to be embodied in the respirator, so that the wearer can be warned if the respirator has accidentally failed.—Compressed Air Magazine.

How to Make Use of Logarithms

The First of a Series of Articles Showing How to Learn the Use of This Method of Shortening Long Calculations. It Will be Continued in Consecutive Issues.

By T H. Fenner

NOW that the Ontario Board of Stationary Engineers allows the use of logarithms in making calculations, there are many engineers who would like to avail themselves of the help that logarithms afford. In making calculations involving long multiplication sums, the work is very much shortened, and a much greater degree of accuracy made probable, owing to the lessening of the liability of error in handling large quantities of figures.

A logarithm, usually called by the abbreviation log, is really a power to which a certain fixed number must be raised in order to produce the number required. The fixed number is known as the base, and may be any number at all, but in the system in general use, known as common logarithms, the base is 10. That is, to obtain any number at all, the base of 10 must be raised to a certain power, which may be a whole number and a fraction, or simply a fraction. Before studying the subject of logarithms, it would be well to study a little the theory of indices, which will enable the student to better comprehend the system on which logarithms are calculated.

Supposing we have a number which is to be raised to the power of two, or in other words squared. That is, the number is to be multiplied by itself. If we set this down in the ordinary way, it will appear, supposing the number is 2, as 2×2, which is 4. Now the first power of 2 is 2, and the second power of 2 is 4. Thus we may say that 2 to the first power, multiplied by 2 to the first power, is 4. Now suppose we take a letter instead of a number, and say a is to be multiplied by a. The product will be a^2. Now, how do we get the second power? We get it by adding together the index figures of the power of the multiplier and multiplicand. Although we do not put in the index figure, which is 1, we imagine it is there, and our sum would appear as:

$$\begin{array}{r} a^1 \\ a^1 \\ \hline a^2 \end{array}$$

Now, if we have, instead of $a \times a$, we have $a^2 \times a^2$ the result would be a^4. Thus we should have $a^1 \times a^1 \times a^1 \times a^1$ which would give a result of a^4. Now if we have $a^3 \times a^3$ the result would be a^5 and if we have $a^2 \times a^4$ we should have a^6.

For instance, the first case would be $a \times a \times a \times a \times a$, and the second case would be $a \times a \times a \times a \times a \times a$. Now let us substitute instead of letters, figures. Suppose we have 2×2, the result will not be 4, but 2. The sum would be

$(2 \times 2) \times (2 \times 2 \times 2)$
$= 4 \times 8$
$= 32$

Now, if we multiplied the figures and added the indexes, we would get $2^2 \times 2^3 = 4^5$ which would be entirely wrong. However, we see that if we wanted the power to which the number two would have to be raised to give 32, it would be 2^5.

This leads to the rule, that when a literary quantity, that is a letter, is multiplied with another letter, the indexes must be added together to give the index of the quotient. Now if you have a quantity like $2a^2$ multiplied by $2a^2$, the answer would be $4a^4$. That is the index of the letters would be added together, but the numbers would be multiplied in the ordinary way. Supposing now that the quantity was enclosed in a bracket, thus (2a), with the index outside the bracket, then this would mean that the whole quantity in the bracket would have to be raised to the 2nd power, and the answer would be 4a. Now if we had two of these quantities enclosed in brackets with the multiplication sign between them thus, (2a) x (2a) the answer would be 4a 4a.

This is arrived at as follows:—Take the first bracket, we have as a result $4a^2$, and this has to be multiplied by $4a^2$. 4×4 is 16, and $a^2 \times a^2$ is a^4, and the sum would appear in detail like this

$(2 \times 2 \times a \times a) \times (2 \times 2 \times a \times a)$
$(4 \times a^2) \times (4 \times a^2)$
$16 \times a^4$

and as 16 to 4^2 the answer would be 4^2a^4. Now if we were to take the figure 2 as the base of a series of logarithms from which we could determine any number by merely raising it to certain powers, we would find that these powers would be largely fractional. Thus if 2^2 were 4, and 2^3 were 8, then 2^4 would be 16. Now suppose we wished to find a number that lay between 8 and 16, it is evident that the power to which we would have to raise 2 would be a power lying somewhere between the 3rd power and the 4th power. The power required would be 3 and some fraction. Now if we were to denote our base 2 by a letter, say a, then to get the number required we should have to multiply the letter a by itself, and add the index of its first power plus a certain fraction together to get the number required. Thus if we wanted the third power of a, we should have $a^2 \times a$ which would give us a^3, and if we wanted the fourth power of a we should have $a^2 \times a^2$. If we want a power between the third and fourth power we should have to multiply $a \times a$, each raised to a power of one and a fraction. Thus if we wanted a number corresponding to the $3\frac{1}{2}$ power of two, we should have $a^{1.75} \times a^{1.75}$, which would give $a^{3.5}$ and the base raised to this power would be the number required. Now the common system of logarithms is a series of powers to which the fixed number or base must be raised to give any number required, only the base on which these powers are calculated is 10, and not 2 as we have stated. As the base is a fixed number, in the tables of logarithms it is not given, all that is given being the index of the power corresponding to the number. Now we have seen that when we multiply we are adding together the indices, it follows that if we know the indices corresponding to any number, and want to multiply, all we have to do is to add the indices of the two numbers together, and we shall get an index corresponding to a number which will be the product of these two numbers. Similarly, if we wish to divide, we shall have to subtract these two indices, to get an index which will be the index of the quotient of these two numbers. That is the theory on which the logarithmic table is based.

Base of Common Logs

Now the base that is used for the common system of logarithms is 10. The logarithm of 1, no matter what system is used will be nothing, for it is quite evident there can be no two indexes which added together would give an index corresponding to 1. If the base of the logarithm is 10, the logarithm of 10 will be 1, that is the index of the power to which it would have to be raised to give itself would be 1 or 10×1. Now the logarithms of all numbers between 1 and 10 must be fractional quantities, for the log of 1 is nothing, and the log of 10 is 1. The log of any number between 10 and 100 will be 1 and a fraction, because the log of 100 is 2, that is the power that 10 must be raised to in order to give 100 as the second power. Between 100 and 1000 the log of any number will be 2 and a fraction, because the power to which 10 must be raised in order to give 1000 is three, thus $10 \times 10 \times 10 = 1000$. So we get for each multiple of 10 an increase of 1 in the index figure, that is in the integral number, not in the fraction. That varies with each number. We can now proceed to define a little closer just what a logarithm consists of.

Characteristic and Mantissa

We have said that every logarithm consists of either a fraction or a whole number and a fraction, or a whole number. The integral part, or the whole number of a logarithm, is called the characteristic of the log, while the fractional part is called the mantissa. Thus the log of 10 would consist of a characteristic, while the mantissa would be .0000000. The log of 1 would be .0000000, while the log of 100 would be 2.0000000. It is usual to carry the fig-

ures of the mantissae to seven places of decimals, in the interests of accuracy, but in many tables they are carried only to four places. From what has gone previously, it will be seen that there is a very simple rule by which the characteristic of the log of any number can be determined. The characteristic will always be one less than the number of figures in the number whose log is required, or in the number of figures into the left of the decimal point where there is a decimal fraction as well as a whole number.

When the number whose log is required is between 1 and 10, there will be no characteristic, the log consisting of a mantissa only. When the number whose log is required is a decimal number, then the characteristic will be a negative quantity. Thus the log of 20 is

1.30103

the log of 2 is

.30103

and the log of .2

$\bar{1}$.30103

The minus sign is written above the characteristic instead of preceding it as is usual in the ordinary way.

When the figure immediately following the decimal point in the number whose logarithm is required, that is of course a fractional number, such as .02, the characteristic of the logarithm will be —2 and the log would be written

$\bar{2}$.30103

and the log of .002 would be

$\bar{3}$.30103

and so on, every cipher following the decimal point adding one to the characteristic of the log, which is always a negative quantity.

In the ordinary tables of logs, the characteristic is not given, the mantissa alone being shown, and the decimal point omitted. This simplifies the table, and there is no chance of going astray on the right characteristic, if the rule is clearly remembered. That is the characteristic of the log of a whole number and fraction, or a whole number is always one less than the number of figures to the left of the decimal point in the number, and the characteristic of the log of a fractional quantity is always a minus quantity, beginning at minus 1 when an integral figure follows the decimal point, and adding one for each cipher that follows the decimal point, and adding one for each cipher that follows the decimal point before an integral figure is reached.

We will follow up this article with further ones in which examples of the working of logarithms are given, and the method of reading the table shown. If every engineer was aware of the help it would be to him to be able to calculate by this method, he would devote a little energy to learning it. A little practice is all that is required to enable any man to become quite familiar with the method, and further more there are some calculations that cannot be made very well without the use of logarithms. Take for instance the formula for finding the mean absolute pressure when the initial pressure, initial volume and final volume are known, which is as follows:

$$Pm = p^1 \frac{1 + \log.e.R}{R}$$

where Pm = Mean abs Pressure
p^1 = Initial abs Pressure
m R = Ratio of expansion ($v_2 \div v$)

(To be continued)

UNIQUE ELECTRIC TRAVELING CRANE

When the first electric traveling crane was built, the builder in all probability did not realize the tremendous possibilities that were opened up for a material-handling appliance of this nature as a labor saving device, and the economical advantages which were to be gained by its use. The diversity of applications of the electric traveling crane and the variety of materials which it will handle to advantage are too numerous to mention here.

One unique application may be seen at the Power Plant of the Union Gas and Electric Company at Cincinnati, Ohio. This crane which was built by the Whiting Corporation, Harvey, Ill. according to specifications issued by Sargent and Lundy of Chicago, who were the Engineers on this work, served as a dredge for an intake well of river water for cooling turbo-generator condensers.

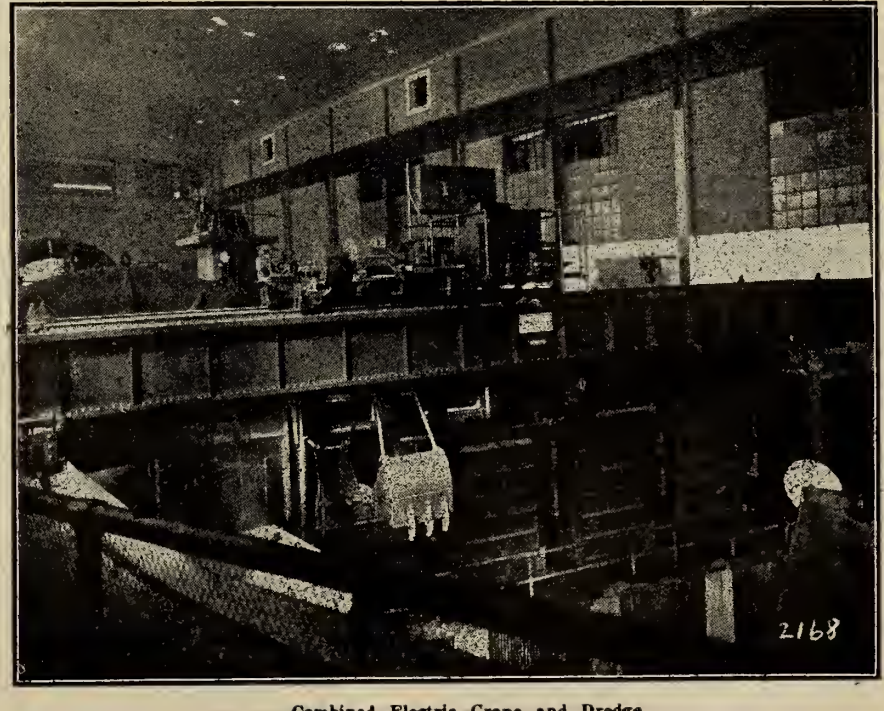
Water is supplied from the Ohio River to the intake well through tunnels and is first cleared of water-logged debris and silt by means of a heavy bar iron grill before reaching the traveling screens behind. This debris and silt is removed from the bottom of the well by means of a grab bucket operated by the crane, and deposited into a hopper. This grab bucket is often called upon to remove heavy water-logged objects such as tree trunks, and it may incidentally be mentioned that on one occasion it brought up a dead cow, very much bloated, from the bottom of the well.

The shape of the intake well is that of a sector of a circle. The crane spans the well radially, having one end truck pivoted at the center of the circle (rotating on a roller bearing at this point), its other end truck traveling on a circular track at the outside edge of the well. This truck is fastened directly to the floor at this level, and a pipe railing is provided around the crane and the operating mechanism of the traveling screens as a safety measure. The crane trolley with its suspended bucket travels along the entire length of the crane bridge or as far in towards the center of the circle as efficient operation of the bucket will permit. The operator's cab is fastened to this trolley extending above the top of the bridge girders and in such a manner as to give the operator an unobstructed view of the bucket and well.

The span of the crane is 49 ft. 10 in., and the trolley is designed for a lift of 100 ft. of the grab bucket which is of ¾ cu. yd. capacity. Two motors of 7½ H. P. each operate the bridge and trolley travel respectively, and two 45 H. P. motors operate the bucket hoist, each one of these motors being equipped with an electric brake.

NEW FORMULA

The Du Pont Company has developed and perfected a formula for the manufacture of straight dynamite which results in that explosive being proof against freezing even in zero temperatures. As a consequence of this development, they have determined to discontinue the manufacture of their former straight dynamite and hereafter all this kind of explosive will be made by the new low-freezing method.



Combined Electric Crane and Dredge.

Welding of a Caulking Edge on a Boiler or Tank

It Pays to Know More Than the Regular Routine of Work—Putting Refractory Plates and Angles in Place—Building Up a Broken End of a Shaft

THE welder who knows only the regular tasks, never goes far. He may hit up against some difficulty, and it is then that his resourcefulness is under test. The matter to follow illustrates and explains some interesting and useful welding dodges, so that those interested in this branch of the business should read each hint carefully, remembering them for future occasions.

For example, Fig. A shows a method of making a lapped plate joint where the edges do not come together flat or the plate bulges between the means provided to hold them together, such as a few bolt holes spaced some distance apart. Another use for this scheme is getting refractory plates and angles in place in ship barge work and perhaps later this scheme will be used in large size ships. The idea is simply to tack a bolt by its head upside down on the lower or inner plate, tacking it by single fillet across two edges only. The heavier plate used as a clamp is then brought down with a nut to bring the upper or outer warped plate into place. After this plate is tacked down and nut can be removed and the bolt knocked off at right angles to the weld or if this proves troublesome, one of the welded beads can be chipped off and then the bolt head can be knocked loose pushing from that direction. This method should be acknowledged to Mr. W. T. Bonner, who devised it and first used it in ship work.

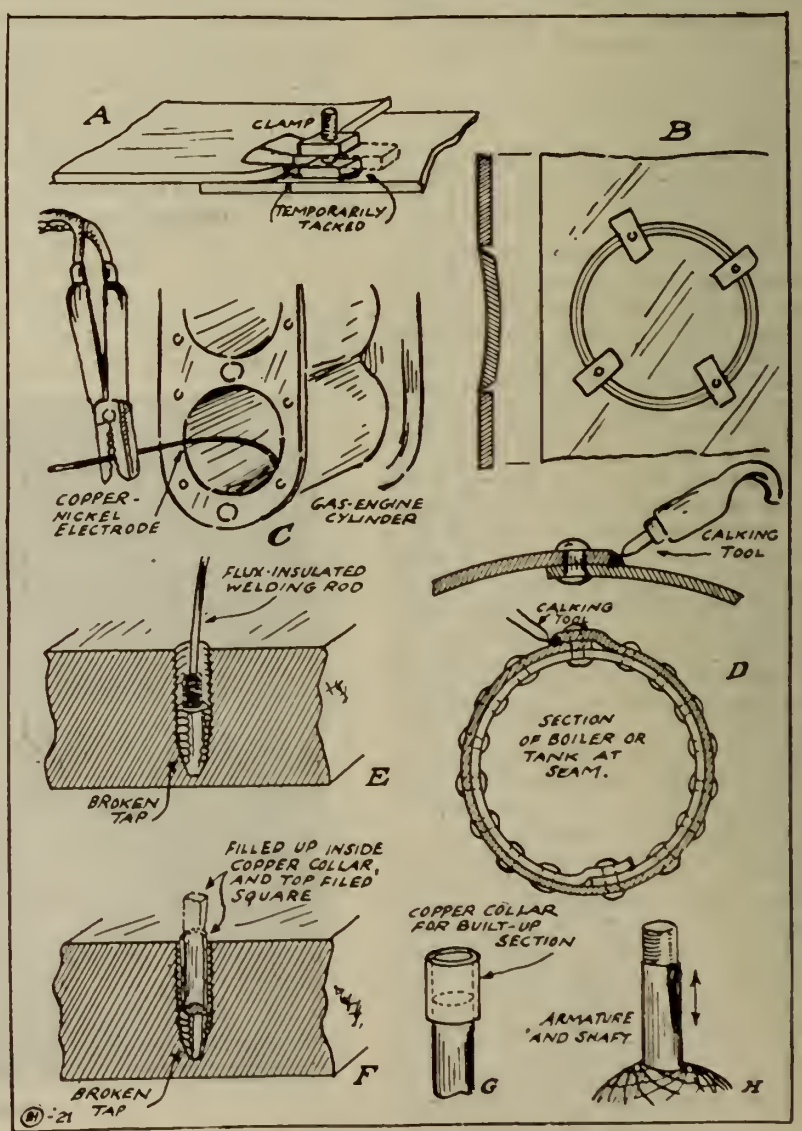
Illustration B shows a method of putting in a patch in a plate whether a plane, round or warped surface where much trouble has been experienced in keeping a welded patch from cracking during the welding or after welding or in service or where from experience such danger is liable. In the cross section you will note the patch is slightly dished, the idea being that the contraction during welding will just about take up the dishing and straighten out the plate that is used as a patch relieving all strains. The ideal patch in this case is a circular one but oft times a true circle cannot be arranged for but the nearer a circle is approached the better the chances are for success. For instance, if the hole is rectangular, rounding the edges will help a whole lot and if the hole is odd shaped, making it an ellipse or egg shape will approximate the circle where the stresses are even all around.

Where a machine formed dished patch cannot be obtained an ordinary sheet can be dished by hammering. If the sheet is over ¼ inch thick it should be hammered hot and it is best hammered hot for any thickness.

The four clamps show an easy method of holding the plate in place, simply putting a bolt through from the inside and clamping down with a heavy plate and nut on the outside. These clamps should be left in place as long as possible in this rigid system of welding. This system not being at all applicable to the non-rigid system as it is a rigid weld with the stress tranferred to the dished patch.

Fig. D shows an apparently easy job to the initiated, that is the welding of a caulking edge on a boiler or tank. This job is far from being easy, because in most cases the welder is called to fix up a leaky seam and the cause of a leaky seam is movement of the plates or rivets. Simply running a caulking edge along the joint will in general make the seam tight when not in use, but upon the boiler tank being put in service, especially under pressure, the plates are liable to assume a different shape or position under load than when quiet, the strain then being entirely brought upon the weld whereat it is broken or pulled away, adequate provision not having been provided to equal the strength of the plates to which it is welded.

It is not always the correct thing to do to make this weld stronger than the plate. In a boiler, for instance, where rivets have been installed for part of the seam, it is best to fire up the boiler and put it under full pressure, thus straining it into its final position before welding. Illustration D shows how a caulking seam should be approached with the tool so as not to drive the weld under the plate. A great deal of experience is needed in caulking for arc welding just as caulking experience is



Sketch shows the various ideas suggested in text matter.

Extracted from a handbook published by the Electric Arc Cutting & Welding Co., Newark, and reproduced through the courtesy of said company.

needed for rivet work. Every boiler maker knows that an amateur will do with a caulking tool more harm than good and similarly in welding; too much caulking is harmful instead of beneficial. A multiplicity of light rapid blows is the only reliable caulking method on a weld, whether the caulking is for a smooth finish or to make the surface denser against weeping. Also, too much caulking will cause the surface of the weld to crumble and repeated caulking of this nature will finally result in crumbling the welding all away.

Caulking rough looking welds for a finish is common practice, but in this case the rougher part of the weld must be chipped or ground approximately the size before caulking, or the efficiency of the weld will be much lowered, both as to strength and tightness. Working a weld cold except on the surface would be similar to working a sheet cold of similar dimensions which could be easily cracked or ruined. Working the weld hot is a different matter, but it is almost impossible to caulk metal arc welding while hot, although in many instances on very careful work each inch or two is caulked while hot (just after it is put down) with a ball peen hammer in the hands of the welder. In very few instances the weld can be reheated and caulked but these are very scarce as reheating would in general cause more strain and stresses than would be relieved by caulking.

Filling In Scored Cylinders

Illustration C shows the proper method of filling-in scored cylinders with the latest development, the copper nickel electrode, which has the property of so merging with cast iron that the usual hard spot underneath the weld is done away with. This copper nickel electrode is far better than the old pure nickel peened in, as the copper nickel can be welded in continuously; care being taken not to get the cylinder wall too hot, that is weld not over two or three inches at a time. The excess metal can be machined off with any common ordinary tool or a lathe or boring mill or can be ground nearly to size and can then be rolled and lapped afterwards.

The illustration shows the electrode bent so that the tip is approximately at right angles to the score to be filled. This is a repetition of previous instructions on this point, i.e. that no arc weld can be made properly unless the electrode tip is very nearly at right angles to the work piece surface. For this copper-nickel electrode even although the score is very small at least ⅛ inch size electrode must be used, as 130 amperes is about the smallest good value that will reliably weld the cast iron and a ⅛ inch electrode is the smallest that will carry this current. For larger work a 5/32 inch electrode is best.

Fig. E. and F. show two methods of reclaiming broken taps in thick pieces or castings, which method is not new by any means. There is nothing more exasperating than to break a tap, especially a bottoming tap below the surface of the main piece. The tap must be gotten out or the work is ruined. If the hole is large an insulated rod can be used to build up on the tap until it is above the surface where a square can be filed on it and tap backed out. The insulation on the rod helps to prevent spoiling of the thread by accidental contact. The method here is to weld a bit at a time or if you have become expert at dipping in and out of the puddle, the building-up can be made practically continuously by shorting the arc in the puddle and pulling away to a very short arc before the puddle freezes. This method is also very useful in building-up oft-times at other places than in a hole.

Where the hole is small an extra tube shoved down inside the threads will allow of the added metal being built-up to the surface in order to file a wrench grip to back out the tap. Illustration G shows a method of building up a broken or chewed off end of a shaft where the end is not more than 4 inches to 6 inches long. The copper collar is here banded on the inside, the collar being not more than 1½ or 2 inches higher than the welding surface at any time, being pushed up successfully as the building up progresses. This method is far better for short pieces than trying to weld on a piece as it does away with the necessity of veeing out, aligning, etc.

After the weld is made the copper collar should be removed and a finish made for subsequent machining by welding lengthwise of the shaft, similarly as is shown on the armature shaft, illustration H. These welds should always be made lengthwise of the shaft in order to ensure an even deposit because in welding around the other way the welding setting is only right for one position and is too hot for the vertical welding and not hot enough for the horizontal. This welding of armature and other shafts, by the way, where the bearing is worn or scored or the keyway is chewed out, is one of the most useful applications of arc welding, as there is practically no danger of putting heat enough into the shaft to melt adjacent babbitt or ruin adjacent windings.

The illustrations on the sheet and angle work show some special applications of joining two or three or even more of the regular structural members for structural work. When joining two plates at an angle, if the sheets are left a bit spread the pieces can be joined reliably in the one weld. The wider the plates are apart, the more reliable will be the joining of the inner three pieces and at no time should the plates be apart a smaller distance than their thickness. The illustration to the right of this shows a method of stiffening a sheet either for attaching to an upright or not.

The angle bending and welding method shown in the center top is one of the most widely used applications of arc welding but is shown as an idea to extend the arc as arc welding is only started. You will note that any angle can be allowed for by cutting out the V to correspond. The illustration to the left of this shows a method of joining by a combination of arc welding and bolts, members which must be removable. The window frame method itself is self explanatory, it being found much easier to chamfer off the window slightly than to make a flush weld and perhaps ending by having to chip the weld. The corner sheet method is similar to the joining of the three pieces explained at the start of this section. A weld made in this manner and finished off a bit is the prettiest joint yet devised.

Where an angle would be objectionable or the plates are small the weld can be butted on the outside at right angles and not welded at all or just welded for finish only.

Unique Method of Welding

A unique method of welding is shown left of this where a lapped joint must be made for a third member and the three of them joined. The illustration shows how one of the plates is nicked out and the other one laid over the notch half way the width of the notch so that the weld can be made through this opening to the third member, at the same time joining the two sheets. The sketch of the veed out plates is shown for several reasons, one that the angle of the "V" must vary with the thickness of the plate for an even flush butt weld, being thicker for heavy plates. In general, however, a right angle opening is the maximum required.

Welding long seams butted brings up the question of the rigid or non-rigid method. In the rigid method the plates are clamped or bolted in their final alignment and the weld made in any manner, either continuously or broken up to spread the resulting contacting stresses over more time and plate. In the non-rigid system the plate is placed close together at one end and the part at the other end and the weld made continuously closing in the opening at an even rate which will just bring the closed ends together at the finish of the weld. This method requires more skill and experience than the non-rigid and in any ordinary job is not worth the trouble it entails, although for very careful work it may be desirable to use it where joining two pieces only.

It is evidently more out of place in setting in a patch as the only part of the patch on which this method can be used would be the first seam. There is a use for it, however, even in setting in patches in some very rare cases where the difference between success and failure depends on getting the first edge of the seam perfect so that it will not be pulled away due to the contracting strains when welding the opposite seams or the seams at right angles which exert a more tearing pull than the opposite seams in contracting.

An aid which is hard to obtain but which has been found very useful in very careful work is to vibrate the work while making the weld by light blows of the hammer or vibrating the work directly after the weld is made, i.e., while it is cooling and contracting. The vibrations of an air hammer set for a light blow is the best means for accomplishing this.

How to Calculate Magnet Windings

Examples of the Mathematical Methods of Determining Number of Turns of Wire, Size of Wire, Loss Due to Rise of Temperature, and Heat Radiating Surface of Coal

By Terrell Croft (Copyright. All Rights Reserved.)

THE DESIGN of windings to excite electromagnets is a rather complicated subject. However, directions are given in following paragraphs whereby windings to satisfy ordinary conditions can be calculated. As in all other branches of engineering, experience is a great asset and is a necessary equipment of one who designs windings most effectively and economically.

Usually the number of amp. turns necessary to produce a certain flux is known, this number having already been estimated. The problem is then to determine the size wire to use for the winding and the number of turns for the winding so that, with a given voltage applied to the winding, a current will flow that will develop the required amp. turns. The winding must also be such that it will not heat excessively and that it will fit into the space prepared for its reception.

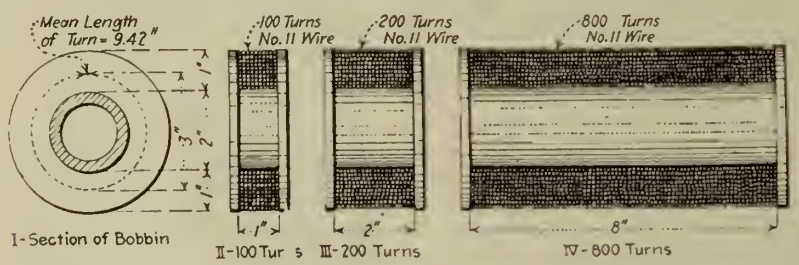


Fig. 1—Illustrating the effect of changing number of turns, the mean length of turn remaining constant.

With a given size wire, a given length of mean turn and a given applied voltage, changing the number of turns does not change the amp. turns. To change the amp. turns of a winding, with the conditions as above, it is necessary to either use a different size wire or to change the applied voltage. If a wire twice as large is used the amp. turns will thereby be doubled. If the applied voltage is doubled, the amp. turns will be doubled. The following example explains the situation.

Example

Consider the winding spaces of Fig. 1. The diameters of all of the spaces are as at I, hence the average diameter of coil or mean length of turn is, in each case, 9.42 in. Suppose that the 1 in. x 1 in. space of II is so wound with insulated wire that it will contain just 100 turns (No. 11 single cotton-covered wire, see a magnet table, will about meet this requirement). See note following for detail calculations. The resistance of the entire coil, 100 turns, in II would be almost 0.1 ohm. Assume that the impressed voltage is 1 volt. Then by Ohm's law, the current that would be pushed through the coil by this voltage would be:—I = E ÷ R = 1 volt ÷ 0.1 ohm = 10 anm. Therefore, the amp. turns of the winding would be:— 100 turns x 10 amp. = 1000 amp. turns.

Now if the coil were made twice as long, as at III, it would contain twice as many or 200 turns. But its resistance would also be twice as great. Hence, although the turns have been doubled, the current has been halved, hence the amp. turns, assuming the same applied voltage (1 volt) would remain 100. With the winding of IV, the turns are increased 8 times but the resistance is also thereby increased 8 times. Hence, ⅛ the current will flow and the amp. turns will remain 200.

Note

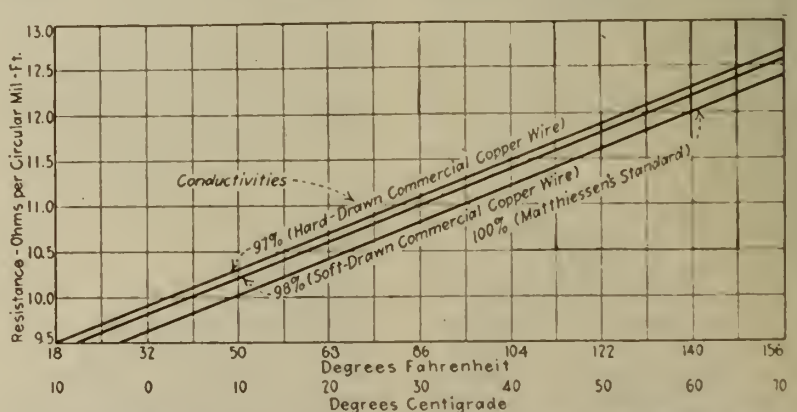
The resistance of the above-mentioned coil was calculated as follows:—The length of mean turn for I, Fig. 1, is 3 in. x 3.1416 = 9.42 in. If the 1 in. x 1 in. space of II is wound with No. 11 single, cotton-covered magnet wire it will contain just about 100 turns. The average length of each turn is:— 9.42 in. ÷ 12 = 0.79 ft. Then in the entire coil there are 0.79 ft. x 100 turns = 79 ft. The resistance of 1000 ft. of No. 11 wire is 1.26 ohms or the resistance of 1 ft. is 0.00126 ohms. Then the resistance of the entire coil is:—0.000126 ohms. x 79 ft. = 0.1 ohm—the value used above.

Increasing the number of turns in a coil having a given length of mean turn and with a given applied voltage decreases the heat developed by the coil. Decreasing the number of turns decreases the heat. Therefore, the amount of wire on a coil, the conditions being as above, determines whether it will operate hot or cool. The size of wire (see preceding paragraph) merely determines the amp. turns. The reason for this is that the heat developed by a current of electricity in any conductor varies as the square of the current. That is, watts heat developed always equals:—I^2 x R. Doubling the turns halves the heating. Other increases or decreases in the number of turns change the heating produced proportionately.

Example

(1) Assume a coil having 200 turns and, say, 20 ohms resistance. If this coil were connected across 100 volts, 5 amp. would flow through it. The heat developed in the coil would then be:— I^2 x R = 5 x 5 x 20 = 500 watts. (2)—Now consider another coil of the same size wire, and having the same mean length of turn, but wound with twice as many, or 400 turns. Its resistance will be twice as great, or 40 ohms. if connected across 100 volts. 2.5 amp. will flow through it. The heat developed by this coil will therefore be:— 2.6 amp. x 2.5 amp x 40 ohms = 250 watts. This is just half of the heat developed by the coil having 100 turns.

The working formula for the calculation of the size of wire for a magnet coil that will provide a required number of amp. turns when connected across a given voltage is the last one in this par-



Graphs showing the resistance per circular mil-foot of copper of different conductivities at different temperatures. (It is usual to specify that hard drawn copper shall have 98 per cent. conductivity and soft drawn copper 97 per cent. Hence commercial copper wire has about these conductivities).

agraph. Its derivation will be given:—

(1)

$$R = \frac{K \times N}{\text{cir. mils}} \times \frac{L}{12} = \frac{K \times N \times L}{12 \times \text{cir. mils}}$$

Wherein.—R=resistance, in ohms, of all of the turns of any magnet winding. K=a constant, (the resistivity of the metal of the conductor) numerically equal to the resistance in ohms of a cir. mil foot of the conductor of the winding. N=the number of turns in the winding. L=length, in inches, of an average turn of the winding—or the length of a mean turn. Cir. mils=cross sectional area of the conductor in circular mils.

If the magnet coil is to operate on some certain fixed voltage, as magnet coils usually do, the current through the coil will be, by Ohm's law, $I = E \div R$. Now substituting the expression for R obtained above in this Ohm's law formula, we have:—

(2)

$$I = \frac{E}{R} = \frac{E}{\frac{K \times N \times L}{12 \times \text{cir. mils}}} = \frac{E \times \text{cir. mils} \times 12}{K \times N \times L}$$

(amp)

Wherein.—I = current, in amperes, through the coil. E=electromotive force impressed on the coil, in volts. Now multiplying both sides of this equation by N, we have:—

(2a)

$$IN = \frac{E \times \text{cir. mils} \times 12 \times N}{K \times L \times N} \text{ (amp. turns)}$$

The two Ns in the right hand member of the equation cancel out giving:—

(2b)

$$IN = \frac{E \times \text{cir. mils} \times 12}{K \times L}$$

and it follows that:—(amp. turns)

(2c)

$$\text{cir. mils} = \frac{I \times N \times K \times L}{12 \times E}$$

(circular mils)

But, for soft-drawn copper wire operating at about 130° F., K becomes (see Fig. 2), 12 ohms. Therefore, where a winding will operate at about 130° F., which is a fair average operating temperature:— cir. mils=I x N x L 12 ÷ 12 x 12. The two 12s cancel out giving as the working formula:—

(2d)

$$\text{cir. mils} = \frac{I \times N \times K \times L}{E}$$

(circular mils)

As outlined in the preceding paragraph, the formulas there given for determining the size wire necessary to produce a certain number of amp. turns are based on the assumption that the winding will operate at a temperature of about 130° F. If the winding actually operates at a lower temperature, the wire size obtained by using the formula in the paragraph just preceding will be larger than necessary. This is because the resistance of copper decreases as its temperature decreases; the graph of Fig. 2, shows how the resistance of a cir. mil-foot of copper varies with the temperature. By substituting the proper value for K. from Fig 2, in the formula given in the preceding paragraph, the amp. turns necessary with any other operating temperature than 130 degrees F. can be easily determined. If the wire for a winding determined in accordance with the formula of the preceding paragraph actually operates at a temperature greater than 130 degress F.. the wire will then be too small rather than too large.

The amount of heat that can be dissipated by a magnet coil without an excessive temperature rise is determined largely by the amount of surface that the coil exposes to the air. It is frequently the practice to assume that there should be the equivalent of 1 sq. in. coil surface exposed to the air for every 0.8 watt of I^2R loss or heat developed by the coil. Experience shows this rule to be safe under ordinary conditions and where it is followed a coil will not acquire a temperature great enough to injure its insulation. A safer practice is to allow 1 sq. in. equivalent for every 0.5 watt of I^2R loss in the coil. It is usually assumed that the heat dissipated through surfaces of the magnet structure, in addition to that dissipated directly from the surface of the coil, amount to from 50 to 75 per cent. of that radiated directly from the coil surface. As a general proposition, no coil that is to carry relatively-heavy currents should be thicker than 2 in.

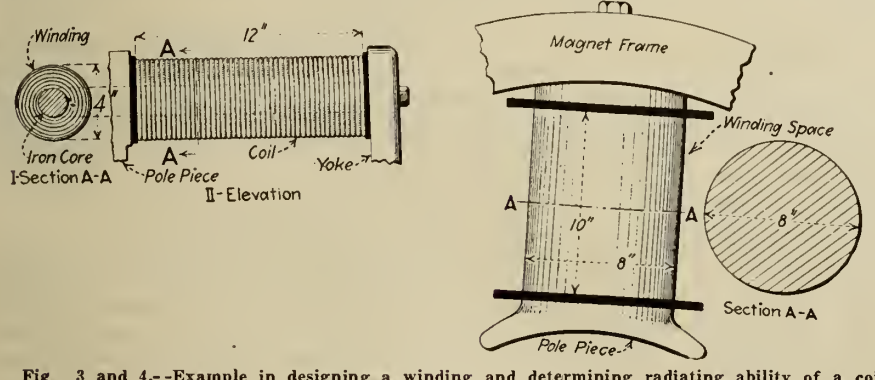


Fig 3 and 4.--Example in designing a winding and determining radiating ability of a coil.

Example

How many watts heat loss can the coil of Fig. 3 dissipate without becoming excessively hot? **Solution.**—Coil is 4 in. in diameter, hence is :—4 x 3.14=12.6 in. in circumference. It is 12 in. long. Therefore, the surface of the coil exposed to the air is:—12.6 x 12=151 sq. in. It will be assumed that the heat conducted into and radiated from the yoke and pole piece will be 75 per cent. of that radiated direct. Then, the total equivalent radiating surface=175 x 151 sq. in. = 250 sq. in. Assuming each sq. in. surface will radiate 0.8 watt, the total watts that can be dissipated by the coil will be 0.8 x 270=216 watts.

The maximum permissible thickness of magnet coils, of cotton-covered wire, that are wound solid—without ventilating ducts—and that may carry continuously relatively heavy currents, is 2 in. Where coils are thicker than this, the heat developed in the inner turns travels slowly to the surface from which it may be radiated. The consequence is, that the inner turns of such coils may become excessively hot. Where the wire comprising the winding is insulated with a non-combustible or heat-resisting material windings may be much thicker than 2 in.

Example illustrating the design of a constant-voltage magnet coil to produce a certain number of amp. turns is given in the following paragraphs.

Example.—Design a winding to produce 11,000 amp. turns for the winding space of Fig. 4. Assume the voltage available to be 110.

Determining Wire Size

(1) Assume that the coil will be 2 in. thick, the maximum permissible thickness (see paragraph just preceding). The magnet core is 8 in. in diameter. Hence, the diameter of mean turn is 10 in. The circumference of mean turn equals:— 10 x 3.14=31.4 in. Substituting these values in (2d):—

(a)

$$\text{cir. mils} = \frac{IN \times L}{E} = \frac{11{,}000 \times 31.4}{110} =$$

3140 cir. mils.

Hence, to produce 11,000 amp. turns under the conditions outlined a 3140 cir. mil winding should be used. Referring to a wire table, a 3140 cir. mil conductor lies between Nos. 15 and 16, American Wire Gage. We will use the larger wire, No. 15. Remember that a 3140 cir. mil conductor will then, produce 11,000 amp. turns, regardless of how few or how many turns of this conductor are wound into the coil.

Ascertain Just How Many Amp. Turns the Wire Found as Above Will Produce

Since with a given voltage, wire-size and mean length of turn, the amount of this No. 15 wire wound on the coil will not affect the number of amp. turns developed, we will find the number of amp. turns developed by 1 lb. of wire. Then the amp. turns developed by a greater or lesser amount of the wire will be the same number.

The length of a mean turn is 31.4 in., is:— 31.4÷12=2.62 ft. From a wire table, 1 lb. of No. 15 wire contains 101.-63 ft. Then 1 lb. of No. 15 would provide:— 101.63÷2.62=38.8 turns. A coil containing 1 lb. of No. 15 would have a resistance of 0.32 ohms. Then a 1 lb. coil would, on 110 volts. pass 110÷0.32 =344 amp. Therefore, the amp. turns of No. 15 wire for the conditions of this ex-

Power Plant Costing

A CORRESPONDENT in another part of this issue has a question relative to the comparative cost of pumping water or buying water from the city, and this opens up a question which is very frequently met with in small power plants. It is questions of this kind and the ability to deal with them that stamps a man as being more than the ordinary operating man, and gives him a chance to become an executive in a large plant. In central stations and large factories, where the cost of power is very closely watched, it is absolutely necessary that the chief engineer or the superintendent of light, heat and power as he is sometimes designated, should be familiar with the methods of obtaining the cost per 1,000 lbs. of steam to his department, and the cost of horse power delivered at his engine room switchboard. In some factories each department is treated as being a separate industry, and is charged for its light, heat and power by the engine room or power department, just as though the latter were a central station and the particular department were a consumer. All repairs to steam piping, electrical apparatus, etc. in that department, are charged up by the power department with the actual time, material and a certain charge for overhead which is based on the overhead charges of the power plant. The overhead charges of the power plant will be the interest on the investment, depreciation, and the sinking fund necessary to replace the entire equipment in a certain number of years. These charges are what are known as the fixed charges. The amount that the department is charged for light, heat and power will be based on the consumption of these three items as nearly as can be determined, and the cost per 1,000 lbs. of steam to the power plant, plus a percentage of the fixed charges already mentioned. The power plant is charged up by the costing department with the cost of coal, oil, repairs, maintenance and overhead, and this cost has to be balanced by the cost to the departments. Now, the foremen of the departments are charged with the cost of the material they perform the operations on, and credited with their value as they leave their department, which is of course the value of the operations performed, and a certain figure to cover the overhead of the department.

Now, if a department shows a high cost for light, heat and power against a low production, or in other words operates at a loss, someone has got to explain. The foreman will naturally try to show that his charges from the power plant are too high, and the chief engineer has got to show that he is producing power at the minimum cost. If he can go thoroughly into these figures himself he knows where he stands, but if he is compelled to except the word of the cost accountant he is liable to get the worst of it.

There is another feature of power costs which is very unfair to the engineer. In some plants total production of material is compared against cost of power, or consumption of coal, and the chief engineer is suddenly called upon to explain how it is that the factory production has dropped 15 per cent, while the coal consumption has remained normal or increased, thus giving a much higher consumption per unit of production. Now what happens frequently is this. A large amount of goods which have had practically all the operations performed on them, have to be scrapped when they reach the final stage. They have had just as much power expended on them, or have required the same consumption of coal as if they had been completed. If the engineer has his finger on his costs he can trace this cause to its source, but if he has not, it may take the executive some little time to discover that there was so much scrap that week, and when he does, it is very doubtful whether he will call for the engineer and explain his mistake.

We do not for a minute pretend that every engineer can be a competent cost accountant, but we do think that every engineer should make it his business to look into this question of power costs to the best of his ability, as such knowledge cannot help but be useful to him, if only for purposes of self protection.

Boilers Still Explode

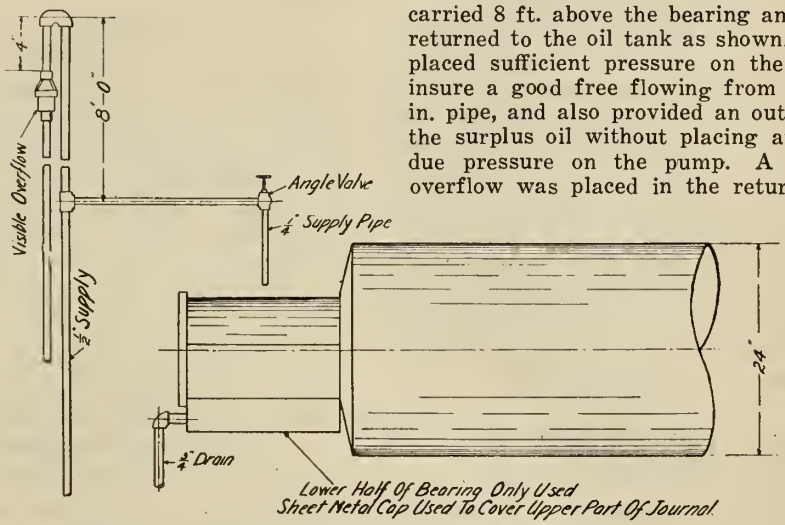
IT IS a remarkable fact that notwithstanding the enormous amount of educational literature and demonstration that has been accorded the steam boiler, that there are still large numbers of accidents yearly happening to these steam generators. We do not hear much about them in Canada, and there are not any statistics easily available, but we do hear occasionally of disastrous explosions. In the United States it seems to be a much more frequent occurrence for a boiler to explode. Of course, there is a vastly greater number of boilers in use in the United States than in Canada, and evidently there is need for a much larger number of inspectors. Glancing over the records of one insurance company alone that issues a statement of explosions coming within its knowledge, we find that for the three months ending March 31st of this year, there were no fewer than 136 accidents, in a little less than ninety days. Of these, no less than thirty were actual explosions, and of these explosions, by far the larger number was heating boilers, working at low pressure presumably. A large percentage of the accidents outside of explosions was due to cracked sections of heating boilers. These figures should go some way to exploding the fallacy that still exists among a large number of people, that because a boiler is operating under low pressure it has but little potentiality for damage. As we have so often pointed out, the damage can be caused as a function, not of the steam pressure, but of the quantity of water above, atmospheric pressure and temperature that is contained in the boiler, and which in turn contains an enormous amount of energy which is liberated when a rupture of the boiler occurs. A heating boiler requires as much care as any other kind of boiler, and this fact should be impressed carefully on the minds of boiler owners and operators till it is universally known and accepted.

The Operators' Point of View

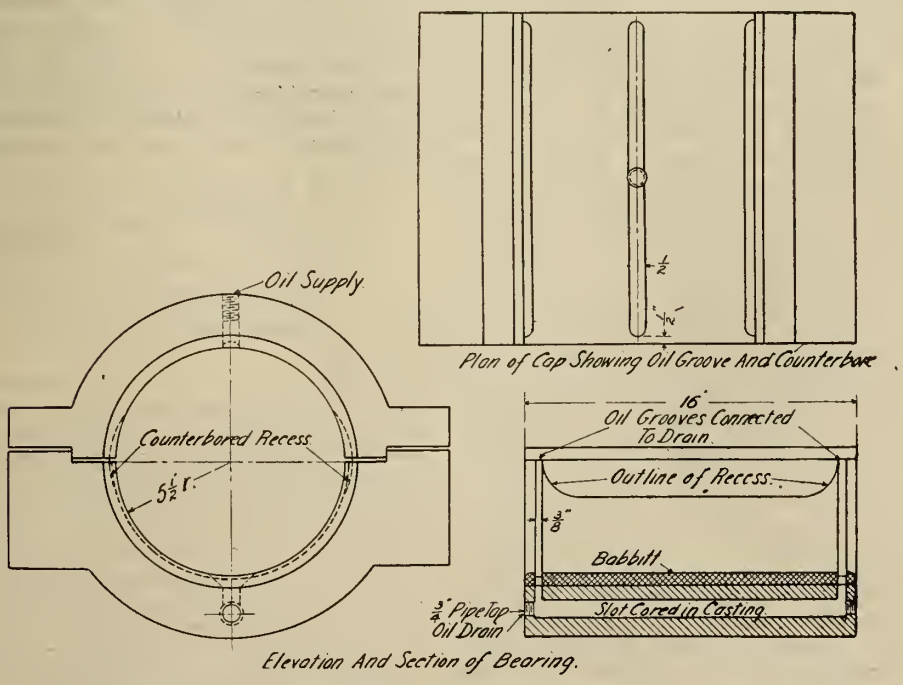
SIMPLE METHOD OF LUBRICATING BEARINGS

After experimenting with various types of bearings, the one which I have shown in the sketches accompanying this article proved most successful. This bearing had to endure a dead load of approximately 150 lbs. per sq. in. projected area and a rubbing velocity of about 6 ft. per min. The bearing was also subjected to considerable heat and had to run hot under the best of conditions. The oil ring type of bearing did not prove at all successful as the oil film was continually breaking down to the slow rubbing speed and the comparative high unit pressure for that speed. The result was a metal to metal contact most of the time as the rings running at such a slow speed could not bring up enough oil to renew the film in the bearing.

A plain babitted water cooled bearing was next tried and, although giving better results as regards wear on the bearing surfaces, it was very wasteful of oil and required considerable attention. The type of bearing shown in the sketch was then designed and proved very successful. It consisted of a plain babbitted bearing with two oil grooves, and a positive, continuous, adjustable oil supply system. The oil reservoir consisted of a tank of about 30 gallons capacity placed far enough below the bearing to allow the oil to drain back into it from the bearing by gravity. A small rotary pump was placed in the oil tank and driven by a chain from a convenient shaft at about 125 R.P.M. A ½ in. supply pipe was used and reduced to ¼ in. over the bearing. This ¼ in. pipe was equipped with an angle valve so that the flow of oil in the bearing could be regulated. The supply pipe was carried 8 ft. above the bearing and then returned to the oil tank as shown. This placed sufficient pressure on the oil to insure a good free flowing from the ¼ in. pipe, and also provided an outlet for the surplus oil without placing any undue pressure on the pump. A visible overflow was placed in the return pipe about 4 in. from the upper extremity. This served as an indicator to see if the oil was flowing freely and prevented the oil being siphoned out of the supply pipe thus leaving the bearing without oil. As the load on the bearing was constant and always in the same direction, the upper part of the box was not used and the exposed journal was covered by a special sheet metal cap to keep dust and grit from the oil and rubbing surfaces. The design of the cap intended to have been used is shown in the detail sketch of the complete bearing. The temperature of the oil used in this system rose to about 40 to 50 degrees above the room temperature and remained fairly constant within these limits. A good quality free flowing light machine oil was used and the temperature rise was not sufficient to cause a break down of the oil film due to decreased viscosity resulting from the increase in temperature.



Sketch is self-explanatory. Shows how bearing is lubricated.



Elevation and section of bearing used.

The oil grooving in the bearing was so designed that the oil would be introduced at a point where the forces acting tend to separate the shaft and the box. At this point a groove was cut in the surface of the box so as to distribute the lubricant evenly over the entire surface of the journal. Having been so introduced it was expected that the oil would adhere to the journal and be carried around to the point where it is pressed against the box with the greatest force, thus forming the lubricating film which separates the rubbing surfaces. As few oil grooves as possible were cut. One at the top of the cap to distribute the oil

over the bearing, and one on each side of the lower half of the box to collect the oil, which would otherwise run out of the ends of the bearing, and cause it to flow by gravity into the lower part of the bearing where the oil grooves are connected to the hole in the box and from which it is conducted by a ¾ in. pipe back to the supply tank where it is strained and used over and over again. In order not to have the oil wiped off the journal before it reached the point for which it was intended, the sharp edges of the box were recessed or counterbored as shown in the sketch.

The upper extremity of this counterbore was connected with the oil grooves at the side so that any surplus of oil would flow into these grooves and back to the tank. The oiling system and bearing just described is simple in construction. The oiling is positive in action and can only fail from the pump breaking down or wearing out and a spare pump should always be kept on hand to meet such an emergency. The bearing has given much better service than those of a more complicated type.

Editor's Note—Who wrote this article? We have by some means or other lost the author's name and address.

BACK PRESSURE HEATING

The Editor "Power House,"

Since "Power House" invited friendly discussion on engineering problems I am taking this opportunity to ask a few questions concerning the article recently published on "The Economy of Working with Back Pressure."

This subject is an important one in paper mills since it is essential that a heat balance be obtained in utilizing the exhaust steam from engines for the various heating and evaporating purposes. Some engines work at a back pressure of only 16 or 17 lbs. absolute while others, which supply steam to the paper machine, operate against pressures of 35 and 40 lbs. absolute.

Taking the example first given in the article referred to steam is supplied to the engine at 100 lbs. gauge or 115 lbs. absolute. Each pound of steam, if dry, will contain about 1188 B.T.U. Now, assuming adiabatic expansion with release at 25 lbs. and a back pressure of 16 lbs. absolute, I figure that the work done in B.T.U.'s per pound of steam to be 143 approximately. The heat absorbed in the cylinder, will even be greater than this when the effect of radiation and other losses are taken into account. Considering these points, are we justified in simply subtracting the total heat of the exhaust as given in the steam table from the total heat of the entering steam in order to get the number of B.T.U.'s absorbed by the engine? If we were using this exhaust steam in the second effect of an evaporator or in a feed water heater, would we be safe in arranging our steam supply on the basis that the exhaust steam still contains 1152 B.T.U.'s per pound instead of the 1045 B.T.U.'s as I have figured it? I ask these questions because the quantities of heat become important items when large volumes of steam are being used.

Taking the other example where there is an initial pressure of 140 lbs. release 55 lbs. and back pressure 35 lbs. with steam initially dry I have calculated the heat converted into work to be about 98 B.T.U.'s per lb. This leaves 1094 B.T.U.'s as available for heating purposes.

I would be pleased to find further discussions on this important subject in "Power House" and to know how others work out their problems in heat distribution.

Yours truly
J. S. Wilson.

In the article the heat losses due to radiation were not calculated, and in an article of that nature could not well be. The idea was to show the general principle underlying the use of back pressure steam. Another article dealing with turbine building for heating purposes appears in this issue. Mr. Wilson's letter opens the way for discussion, and opinions from other readers will be welcomed.

Editor

EFFECT OF EXCESS AIR ON EXIT GAS TEMPERATURE

"The fourth loss (loss due to heat carried away in dry chimney gases) is more truly a combustion loss, though since it is affected by exit gas temperatures this too is dependent on boiler design. Obviously, with a given fuel, and for a given exit gas temperature, the greater the gas weight, i.e, the greater the excess air, the greater the loss of heat in the chimney gases. This loss is kept at a minimum when complete combustion is made to approach perfect combustion.

It will be noted from the foregoing that the two main factors upon which the extent of all combustion losses depend are the amount of air supplied for combustion and the temperature of the gases leaving the boiler surfaces.

The factor of air supply can, within limits, be controlled, but if we assume the ability of a boiler to absorb heat efficiently, the factor of exit gas temperature can only be controlled to the extent that it is dependent on an air supply. In view of this fact the effect of air supply on exit gas temperature must be considered.

On first thought it would appear that since large quantities of excess air introduced into the furnace would reduce the temperature of the products of combustion before the boiler heating surfaces are encountered, such dilution would result in lower exit gas temperatures, and it is of course entirely possible to carry this dilution of the products of combustion in the furnace to a point where such a decrease in ultimate temperature would result. In practice, however, even where the amounts of excess air correspond to the most inefficient combustion, this excess instead of decreasing, tends to increase the exit gas temperature. The common explanation of this apparent phenomenon is that the excess air in passing through and mingling with the actual products of combustion absorb heat from such products more readily than will the boiler heating surfaces, and a considerable portion of the heat so absorbed is carried off in the escaping gases. Such a statement offers by far the simplest explanation, and one which accounts for a part at least of the increase of exit gas temperature with an increase of excess air. The other factor leading to such a result is dependent on heat transfer rates, difference in temperature between the gases and the absorbing surface the percentage of total heat absorbed through radiation and the percentage of total absorption through connection." The above is an extract from "Principles of Combustion in the Steam Boiler Furnace," by Arthur D. Pratt, and published by the Babcock and Wilcox, Co.

"The common explanation etc.," given by Mr. Pratt does not appear to me to be the correct one. This explanation will account for heat loss through excess air, because if two volumes of air beat the same temperature but one volume be twice as great as the other the greater volume will contain twice as much heat as the smaller volume. This shows us that the exist gas temperature alone will not show the heat lost up the stack. In my opinion "the other factor leading to such a result is dependent upon heat transfer rates etc." is the true explanation even if it does lead to a complication of theories as claimed by Mr. Pratt. It is easily understood that when an extra furnace is added to a boiler as is sometimes done in the case of some water tube types when the demand for more capacity is very urgent that the exit gas temperature will unavoidably be higher although the furnace temperature may not be higher. That the increased volume of furnace gases is the cause of the increased exit gas temperature is also easily understod. If the volume of the furnace gases is increased the heat absorbing surface should also be proportionately increased otherwise we may expect higher exit gas temperature.

A CHALLENGE

Editor Power House
Dear Sir—

In "Power House" of Oct. 30, a correspondent bewails the fact that so few Canadian Engineers write to their engineering magazines. I will merely relate an incident and then listen for the answer. About 18 months ago Henry Wright of Montreal explained a tube failure in one of a battery of water tube boilers. During the mixup water went over and gave a turbine a hard run for a while but as there was nothing stronger than 2½% in it, which is strange for Montreal, there was no damage done in that quarter although there was at

least one fatality in the boiler room. Mr. Wright asked the opinion of engineers as to the source of the water (which boiler) and as far as I know I was the only one to hazard a guess. Your correspondent so far has not risked his reputation by expressing an opinion. Neither has Mr. Wright told the world whether my guess was right or otherwise, and I would like to know. Now, Engineers, we are listening.

R. McLaren,
160 Dovercourt Road,
Toronto.

TORONTO NO. 1, C.A.S.E.

The regular meeting of Toronto No. 1 Lodge C.A.S.E. was held at Cumberland Hall on Nov. 15th. The regular business of the Lodge being disposed of by nine o'clock, the meeting was handed over to the educational committee, who were easily able to keep the audience interested.

The question box received the first attention, and the answering of the questions found brought out some interesting discussions. Mr. Geo. J. Soucy then gave a very interesting talk on internal combustion engines, tracing the subject from the earliest records to the present day. He illustrated his talk by a number of charts and diagrams, leading up to the development of the double piston two cycle engine, such as is being made in various forms at the present day. He showed the possibility of its application to the automobile field, and its application to marine uses in Great Britain where a number of engines of 3000 h.p. have been built on this principle. The meeting was well attended, and the members expressed much satisfaction with the programme.

WOODSTOCK C.A.S.E. LODGE

Woodstock Lodge, No. 37, C.A.S.E. held a very interesting and successful meeting on the evening of Nov. 14th. The lantern was used for the first time, and Brother Arnup showed a number of different types of boilers on the screen, at the same time explaining the various points of each. The attendance was good, and those present were unanimous in hoping for a continuation of these meetings during the winter.

CATALOGUE

Atlas, Ideal and Victor Reducing Valves, Pump Governors, Pressure Regulators, Hot Water Tank Regulators, Control Valves and Damper Regulators are described in Junior Catalogue No. 21 just published by the Atlas Valve Company, 282 South Street, Newark, N. J. This little catalogue of 20 pages gives complete information—illustrates, describes, lists all sizes and gives prices. A copy will be sent free on request to any reader of this publication.

HOW TO CALCULATE MAGNET WINDINGS

(Continued from page 33)

ample are:—344 amp. x 38.8 turns= 13,350 amp. turns.

Whether 1,10,100 or 1000 turns of No. 15 wire were wound on the core of Fig. 4 (with a mean diameter of turn of 10 in. and an applied voltage og 110) the amp. turns would remain at 13,350.

Determine Heat Radiating From Surface of Coil

The outside diameter of the coil will be 12 in. Therefore, its circumference will be:—12 in. x 3.14=37.7 in. The exposed area of the coil will be:—37.7 in. x 10 in.=377 sq. in. Assume that the pole piece and frame provide a radiating surface 75 per cent. as great as that of the winding. Then, the total, equivalent radiating surface is:—377 x 1.75=660 sq. in.

Determine Watt Power Loss Permissible in the Coil

(4) Assume that each sq. in. of equivalent coil surface will radiate the heat produced by 0.5 watt. Then the coil can effectively radiate the heat due to:— 0.5 x 660=330 watts.

Determine Permissible Current in Coil

(5) With a pressure of 110 volts, the current that will develop 330 watts is:— $I=P\div E=330$ watts $\div$ 110 volts=3 amp. Therefore the permissible current in the coil is 3 amp.

Determine Amount of Wire Required

(6) Through a coil of 1 lb. of No. 15 wire (as calculated in (2), 344 amp. will flow. As determined in (5), the permissible current through the coil of this example is 3 amp. To pass a current of 3 amp., a coil of No. 15 wire weighing:— $344\div 3=115$ lb. would be required. We will then use 115 lb. of No. 15 if it will fit in the winding space available. Since there are 101.6 ft. in 1 lb. of No. 15 bare copper wire, the length of wire in the 115 lb. coil required in this problem would be:—115 x 101.6=11,700 ft.

Check Wire Size to Ascertain if it Can be Wound in Space Available

(7) We must find room for 11,700 ft. of No. 15 wire which must be insulated. The thickness of the coil is 2 in. and its length is 10 in. The cross section of the coil is, then:—2 x 10=20 sq. in. Assume that single, cotton-covered magnet wire will be used. From a magnet table, 1 sq. in. will contain 249 such wires or turns. The 20 sq. in. will contain:—20 x 249 = 4,980 turns. The mean turn has as determined in (2), a length of 2.62 ft. Then, total length of wire that can be wound in coil is 2.62 x 4980 = 12,050 ft. It is, then, evident that there is ample room for the 11,700 ft. that is necessary, as calculated in (6).

Magnet coils operating on constant current, such as coils, of constant-current or series generators and series street lighting system magnets, always have practically the same current flowing through them. Therefore, with such coils the wire size merely determines the I^2 x R loss or heating in the coil. Where such a coil is to be designed, divide the amp. turns required by the amp. flowing in the constant-current circuit; the result will be the number of turns required. Use a size wire that will carry this current without excessive heating.

PECULIAR REPAIR JOB

A job which has been bothering expert engineers for some weeks past is the repair of the Bascule bridge over the St. Mary's American ship canal, and said to be the largest bridge of its kind in the world. Early in October, gusset plates were found torn in the bridge with the counter weight at the southern end of the jackknife displaced. One support beam was broken and another badly twisted, and C. P. R. connections across the bridge were held up for over a week, while 100 men were rushed from Chicago to effect repairs. Traffic has been resumed, but the southern span has to be kept stationary, and cannot be raised. The cause of the trouble originally is believed to have either been from a flaw in the material in the gusset plates, or from some sudden impact on the bridge. The structure has been in operation since 1914, and by reason of its opening up in the centre, by means of counterweights at either end, with the spans raised perpendicularly, it is known as the "Jackknife bridge." The counterweight at the south end was lowered four inches out of place. It is a cement block 1400 tons in weight and to get it back in place with a limited amount of room for the workmen proved difficult. Over 30 jacks were used, fifteen 100 ton compressed air jacks, ten 50 ton jacks, and five smaller ones were put in service. Over 50 men were employed on the jacks alone.

The annual meeting of the Canadian National Newspapers and Periodicals Association, took place in Toronto on Nov. 10 and 11, and many interesting papers were presented. On Nov. 10, a luncheon was held at the King Edward Hotel, at which many prominent speakers took part including the new Lieut. Govenor General for Ontario. His message to the business and technical papers of the country was especially inspiring. He pointed out that Canada was passing through a very critical period, and that it was up to the editors of the various business, religious, technical and kindred journals to lead, and lead carefully. The power of such periodicals was pointed out, and his Honor concluded by saying that he felt Canada would come through with great success as we had as our backbone a wonderful country in itself.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

INTERNAL COMBUSTION ENGINE

Question:—In a certain write up on automobile motors, the writer had this to say. Supposing we had a motor with 3⅝″ bore and 4½″ stroke and another with 3⅝″ bore and 4″ stroke. This ½″ extra length of stroke would as a matter of fact add 5 or 6 h.p. to the former.

Now an increase in the length of stroke means an increase in the length of crank webs. The angularity of connecting rod would also be reduced and if both engines were running at the same speed the piston velocity of the motor with the longer stroke, would be greater. If both motors had the same piston velocity this would necessarily mean that the motor with the longer stroke would have a lower rotative speed. If this is so, and, with equal piston velocities it would be, just what advantage is claimed for the long stroke motors compared with those of shorter stroke, but with same bore?

Answer:—A motor with a longer stroke and same bore as another motor is able to avail itself of a greater range of expansion, or greater range of temperature, which tends to increase its efficiency. If the M.E.P. is the same in both motors, the I.H.P. will be the same with equal piston speed, but the gas consumption should be less in the long stroke engine. With the same gas charge the M. E. P. should be greater in the longer stroke engine. In the longer stroke engine less heat will be given up to the cooling water, and more utilized in the cylinder.

The angularity of the rod is not affected by the length of stroke, but by the proportion of length of connecting rod to length of stroke.

A MOTOR TROUBLE

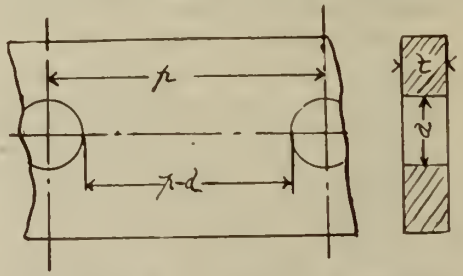
Question:—Could you please answer the following question in your next issue of Power House. We have an oil burning system which is operated by a half horse power motor. This motor is operated and controlled by a 110 volt d.c. rheostat. Recently I left the motor running in good order, and was away some little time, and when I came back found the motor stopped, but with the motor still in circuit, the rheostat being in the same position as when I left. I made close inspection of the whole system, and found everything o.k. excepting the motor was beginning to heat. On releasing the switch the control arm of the motor came back to the off position. The switch was put in, and the motor started up again with the rheostat without any further trouble. What was the cause of the motor stopping?

Answer:—This is rather difficult to say positively. We presume that the motor in question is arranged as a variable speed motor. The source of current is not stated, that is whether it is supplied from an outside agency or is generated on the premises. It is quite possible that the voltage may have dropped in attendant's absence, and the motor was pulled up by not having sufficient torque to overcome the load. There could still be enough current passing through the control to energize the magnet and hold the control arm against the armature in the full open position, or if in a position for slow speed the control arm would remain open anyway. If the motor had remained in this condition very long the winding would probably have burned out or the fuse blown on the main switch. The condition probably only lasted for a very few minutes or perhaps less than a minute before the attendant returned. Some of our readers may be inclined to put forward some theories, which will be welcomed.

CRUSHING STRESS

Question:—Would you please explain in the next issue of your paper what is meant by a crushing strain, and where it takes place in a steam boiler.

Answer:—A crushing stress is really a compressive stress, and may occur at various parts of a boiler, such as combustion chambers of Scotch marine boilers, internally fired furnaces, etc. The term crushing is usually applied however, to the stress on the metal outside of a rivet hole that is extending



from the edge of the hole to the edge of the plate. If you could imagine in the case of the single riveted joint illustrated, that the plates were torn apart, not by the plate tearing between the rivet holes, nor by the shearing of the rivets, but through the metal from the edge of the rivet hole to the edge of the plate being crushed against the rivet, you have the idea of the crushing stress referred to. The strength of the metal to oppose this stress is very high, about 50% greater than the tensile strength, and thus there is little danger of the joint failing in this manner.

COST OF PUMPING

Question:—We find it necessary to elevate water about 55 feet to a tank from where it returns by gravity to various parts of the building, where it is used for various manufacturing purposes. There is sufficient water available from the ammonia condenser, which could be pumped into the tank, but it is argued that it would be cheaper to use city service water. How would the cost of pumping such water be calculated i.e. the cost of pump, not counting cost of connections and connecting up, steam for operation, maintenance repairs and depreciation, spread over a period of five years, and other factors that are necessary of consideration? An example of such a calculation using any convenient quantity of water, would be greatly appreciated.

Answer:—The question of whether it is better to use power or buy city service water, independent of what is required for the ammonia condenser, would seem to be governed by the fact first of all that the city pressure would hardly be sufficient to raise the water to the height required. However, if it is a question of whether if the city water was of sufficient pressure to raise itself the required height, would it be cheaper to put in a power pump or steam pump, and use water already having served one purpose, or purchase a separate supply altogether.

Suppose the quantity required was 1000 gallons per hour. A steam pump for this quantity could be purchased for about $240, and then there would be the cost of maintenance and repairs to consider, as well as the cost of steam to drive it. One thousand gallons raised 55 feet is equal to 550,000 foot lbs. per hour, or roughly 10000 foot lbs. per minute which is about one third of a horse power The probable steam consumption of a pump of this kind would be in the neighborhood of 120 lbs. steam per hp. hour, or in this case about 40 lbs. steam per hour. The cost of steam will vary according to the efficiency of the plant, but we could roughly reckon on 5 lbs. coal per hour, and this for a ten hour day would be 50 lbs., and for twelve months of 300 total working days, 150000 lbs. of coal. If this coal costs $8 per ton the fuel cost would

then be for 1000 gallons per hour about $60 per year. The investment cost would be $15 per year, and the depreciation $24 per year. Repair and maintenance for a pump of this kind would cost at least 10% of the total cost of the pump per annum, or say $24 per year, and might be higher. The total cost would then be about $113 per year. This allows nothing for replacement, and it would be necessary to place a certain sum in reserve each year for this purpose, which should be sufficient to replace the cost of the pump by the time that the depreciation has amounted to the full value of the pump, or in other words, when the pump stands at nothing in the equipment value, a sufficient sum should be on hand to replace it. This would add another $24 per year to the cost, and bring it up to $127 per annum. Different firms have different methods of taking care of depreciation and replacement costs, but this method allows for practically all charges.

Now with city water at 13 3-4 cents per 1000 gallons, and a consumption of 10,000 gallons per day for 300 working days, the cost would be $412.50 per annum. The difference in cost in one year would be enough to pay for the pump and all charges. The cost of pumping would probably be much less if a motor driven centrifugal pump were used, of if a shaft is available, a power driven pump. There is the question also to be considered if it would not be possible to deliver the water direct into the service pipes, without the expense of a tank and connections. In this way, with a suitable governor on the pump, water would only be supplied in sufficient quantities to maintain the pressure on the mains, and there would be no loss through the overflowing of the tank which invariably occurs at different times.

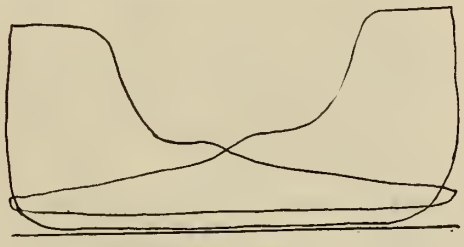
A question of this kind involves a very large number of factors, but it seems to be impracticable to purchase a second supply of water when there is water available that has already been paid for. The question of water supply for a large factory is always an important one, and wherever it is possible to secure water by means of a private well, or location on the banks of the river or lake, considerable savings can be effected.

If larger quantities of water have to be handled, then the cost would be altered in this way. The proportion of investment cost would be lower as the cost of a larger pump is not proportional directly to the size, but decreases with increase in capacity. Thus a pump for 2000 gallons per hour would not cost double that of a pump for 1000 gallons, but probably only one and a half times as much. As the size increases the efficiency of the pump, or the foot lbs. delivered per heat unit consumed becomes greater. Maintenance and repairs remain about the same proportion, and attendance will be the same, the ordinary staff of the engine room being able to take care of a large or small pump without any increase. Extra time spent would of course come under the head of maintenance.

AN INDICATOR CARD QUESTION

Question:—Will you tell me through the columns of Power House what is the matter with this indicator card, whether the trouble is in the engine or the indicator. The card is taken off a Brown engine carrying 130 lbs. initial pressure and running a 120 barrel flour mill.

Answer:—We presume that the fault referred to by our correspondent is the hump that appears in the expansion



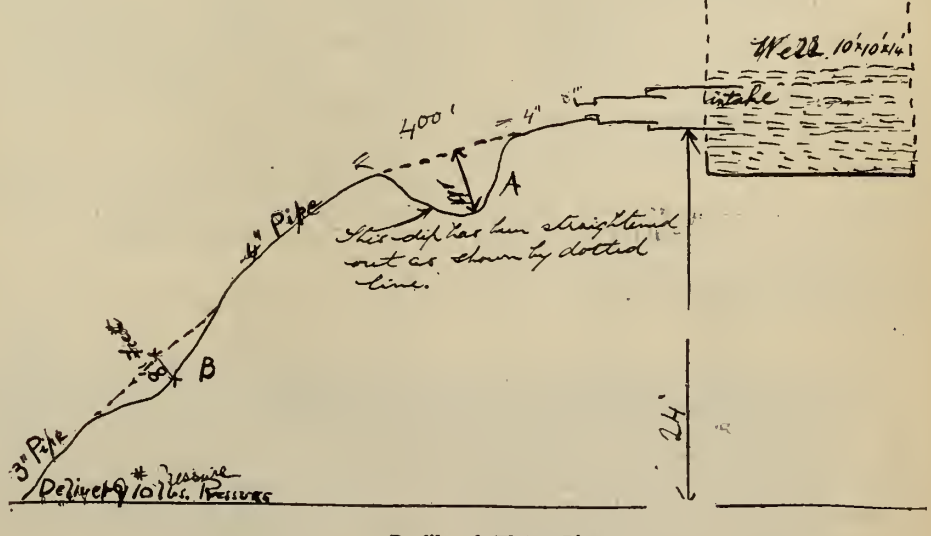
What is wrong?

line on both ends of the cylinder. This would appear to be a defect in the indicator, and is probably caused by the piston of the indicator cylinder. There may be a hard spot caused by oil having carbonized, or perhaps the indicator has been put away wet, and a rough spot has been formed by a little local corrosion. As the hump appears at both ends of the engine cylinder, and at exactly the same height on each card, it would appear to us that it is clearly an instrument fault. Perhaps our readers will not agree with this view, and we shall have some comment. There is another peculiarity of the card, which is not due either to the engine or the indicator, but to the one who traced the card. Our readers will notice this at the first glance.

LOSS OF PRESSURE IN PIPES

Question:—I have been troubled quite a lot lately with a water supply to a power house, through not being able to get a sufficient supply from our own well. We have also had to buy water from the city when our own well still had water in it, but we could not get it to the power house in sufficient quantities. Our well is about two miles from the power house, and has a gravity flow which must have a head of 24 feet, as we get about 10 lbs. pressure at our delivery. The well is 10 ft. sq. and 14 feet deep, intake pipe at well is 10 inches inside, for twenty feet, and is then reduced to 8 inches, again to 4 inches, and finally to three at delivery. The pipe was at one time reduced to 4 inches to 2 inches then came back to 4 inches and again to 2 inches. I took out 500 feet of two inch pipe and put in three inch expecting to get a better flow but got no more out of the 3 inch pipe than I got through the two inch pipe. At one part of the pipe line, pipe took a drop of 11 feet in 400 feet then came back to level again. I took this loop out and ran pipe on gradual grade. Close to the power house the pipe has to raise 8 feet again to suit grade of road, and I don't know if that is all the cause of our shortage or not. Sometimes we get as much as three hundred cubic feet per hour with the same amount of water in the well as at other times when the flow is only two hundred cubic feet per hour. I have tried every way I know to chase the water down but cannot succeed, and am enclosing a rough sketch. When we have a ten inch pipe full at well, we cannot get a three inch pipe full, at delivery. Can we overcome this without the aid of a power pump?

Answer:— Judging from the layout of the pipe as shown in the sketch, it is not surprising that there is difficulty in getting a steady delivery of water. The fact that you get 10 lbs. pressure on the delivery would seem to indicate that the head of water is considerably over 24 feet. In a slope of 12 feet to the mile, the loss of pressure per 1000 feet of length is approximately 1 lb. per sq. in., and as your pipe is over



Profile of Water Pipe.

10,000 feet long, and full of kinks, you would get but little delivery if the water had the head given by you. 300 cubic feet per hour is only .083 cubic feet per sec. which is velocity in feet per sec. of 1.7, or 102 feet per minute.

The piping is too involved to attempt to calculate the flow, but you are getting about the flow you could expect if your piping was 3 inches diameter, and the slope was 24 feet in 10,000. The remedy would seem to be to straighten out the pipe, and provide ample area for the quantity of water you require, under the actual head, which you can obtain from a profile map of the country. Putting in a power pump with the existing piping would simply mean that you will create an artificial head, at the expense of the power necessary, in order to overcome the friction of the piping as it exists. We should imagine that the amount of expense at stake would justify the employment of a surveyor to discover the exact conditions of head, and the possibility of running a pipe with a direct slope to the power house, as free from bends as can possibly be done. From the sketch it would appear as though the 8 foot dip could be straightened out to advantage.

SOME INTERESTING QUESTIONS

Question:—In the case of a pair of slide valve engines 14 by 18 inches running at 210 r.p.m., boiler pressure 140 lbs. per square inch, and cut off at three quarter stroke, what horse power would they deliver at the saw?

Answer:—The horse power delivered at the saw would be the product of the indicated horse power and a factor which would cover mechanical losses in the engine and the transmission apparatus, and would of course vary. The indicated horse power would be four in the usual way, and with cut off at three quarter stroke, the ratio of expansion would be the volume up to cut off divided into the final volume, 4-3, or 1.33 The mean pressure can be obtained by formula

$$Pm = pl \frac{1 + \text{hyp. log } R}{R}$$

which is

$$Pm = 154.7 \frac{1.122}{1.333}$$

in which Pm is the absolute mean pressure and pl is the absolute initial pressure and R the ratio of expansion. The hyperbolic log is the common log × 2.302.

This gives a mean effective pressure by the formula of 115.3 lbs. per square inch. Filling in the other factors in the horse power formula we have

$$\frac{14 \times 14 \times .7854 \times 115.2 \times 1.5 \times 420}{33000} = 368.8$$

Multiplying this by 2 as there are two engines we have a horse power of 737.6. The brake horse power of the engines would probably be .95 of the indicated, which would give 700.7 horse power available at the fly wheel. The power then available at the saw would depend on the efficiency of the transmission

Cards from Sawmill Engine.

from the engine flywheel to the shaft of the saw, and might vary within fairly wide limits, according to the system used.

A card from these engines is here reproduced, but our correspondent has neglected to mention the scale of the spring used, so that we cannot work out the indicated horse power from the diagram. Our correspondent further asks the following question. Would same engine be considered ample to drive a sawmill to cut 140,000 feet of lumber in a 10 hour day? This is a question we cannot answer off hand, as there are such a large number of factors entering into it. Could any of our readers who have had large sawmill experience let us have their views on this question, which is an interesting one?

While still on this subject, the question is put. "Would you consider engines of ample power, if they could be pulled down dead with only bottom saws in log, when both top and bottom saws have to be buried in the log 30% of the working time?" Again the information is hardly sufficient for us to answer it very positively, but on the face of it, we should not. Here is another question that our saw-mill friends should be able to offer information on.

Would engines give better power with two governors 3½ diameter or one 5 inch governor?

Providing the governors are set to work at the same speed, the engines being identical, we do not see as far as the power is concerned that it would make much difference. There is this point, that if the engines are supplied from a common steam pipe, and drive a common fly wheel, it would be preferable to have a single governor controlling admission of steam to both cylinders at the some time and this would give closer regulation.

The last question of the series is as follows. "Which would be the more efficient, a pair of 14 x 18, at 210 R.P.M. or one single 18 x 24 inches at 200 R. P. M.?"

We presume that what is required is the power and not the efficiency particularly. As a question of pure thermal efficency, the single engine would probably show up the best. From a horse power point of view, allowing the same mean effective pressure for both engines, we have for the pair of 14 x 18 with 115 lbs mean pressure 737.6. With the same mean pressure the 18 x 24 inch engine at 200 r.p,m. would give 709.4 indicated horse power. Such an engine would be less in first cost. In a sawmill it is not generally of much importance whether an engine is economical or otherwise in steam consumption, the main thing being to get the power. There is usually more fuel available than can be used, at least, this has been our observation of sawmill practice.

POWER FOR CIRCULAR SAW

Question:—In the case of a circular saw 56 inches diameter having forty teeth, in changing it for one of the same diameter and same width of tooth, speed and condition being the same, but with 46 teeth, which saw will take the most power?

Answer:—Changing the number of teeth on circular saw from 40 to 46 is so slight a change that there will be but little difference in the operation. However it has been proved by experiment that increasing the number of teeth in a saw for the same diameter, or in other words decreasing the pitch of the teeth, causes more power to be required in accomplishing the work of the saw. The reason given is that there being a larger number of teeth in the log at one time, the friction is greater, and although there is less work on each tooth, in the aggregate the power required is greater than with the smaller number of teeth.

BOILER HORSE POWER

Question:—What will be the horse power of a boiler 6 feet diameter by 16 feet long, with 88.3 inch tubes?

Answer:—The rated horse power is 1/15th of the heating surface and the heating surface will be half the circumference by the length of the shell, added to the circumference of the tubes in feet by the length of the tubes and their number.

$$\text{H.S.} = \frac{16 \times 6 \times 3.1416}{2} + \frac{3 \times 3.1416 \times 16 \times 88}{12}$$

$$150.79 + 1105.8 = 1256.59$$

and the horse power will be 84. The actual horse power developed under natural draught may be taken as the fire grate area x 3, which would be 5x5.5x3 =82.5.

ANNOUNCEMENT

The Westinghouse Electric & Manufacturing Company announces the following changes in its Service Department: B. B. Burkett has been appointed District Service Manager in the Seattle Office, succeeding N. P. Wilson, who has been transferred to Sales Service activities in the Seattle territory.

The Salt Lake Service Department has been made a branch of the Denver Office, under the direction of A. F. Maccallum, District Service Manager, Denver. M. R. Davis, formerly District Service Manager at Salt Lake, will remain at Salt Lake and devote his time to field service work and to securing repair business for both shops.

Handling Coal and Ashes in the Modern Power House

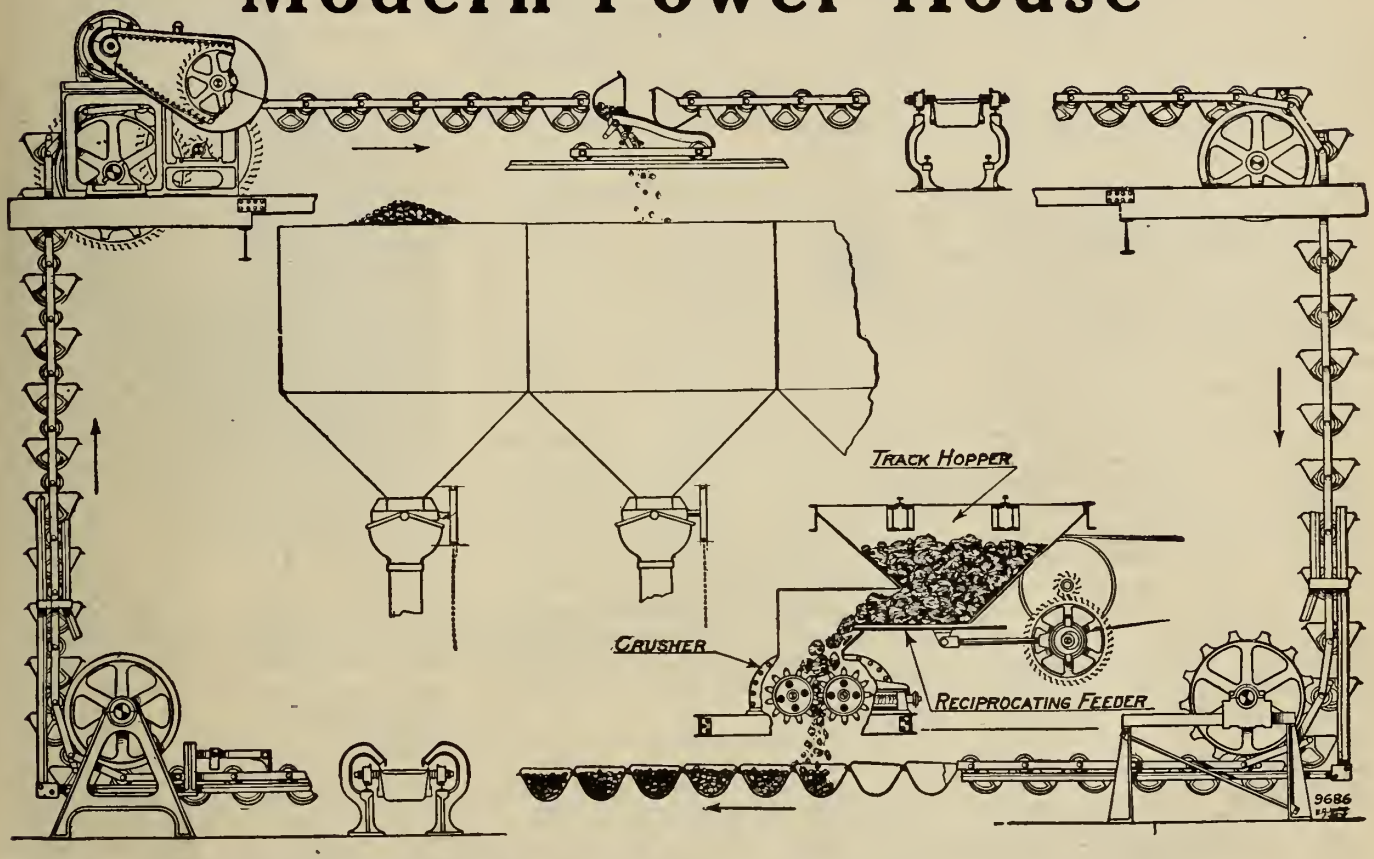


Diagram Showing Operation of the Peck Overlapping Pivoted Bucket Carrier

THE Records of Performance of our Peck Carrier—an overlapping pivoted-bucket machine for handling coal and ashes in power houses—merit the close attention of Engineers and those who contemplate the installation of such equipment.

The Peck Carrier is the recognized standard carrier for coal and ashes in the modern power plant. It has earned an enviable reputation for satisfactory operation and low upkeep costs.

The maintenance charges of the Peck Carrier during the early years are almost negligible. Let us show you some of these records. Send for one of our Engineers.

Value of Boiler Inspection

We here reproduce an article on the value of boiler inspection, which appeared in the "Locomotive," the journal of the Hartford Steam Boiler Inspection and Insurance Co. After a few preliminary words the article goes on as follows:—

Some years ago a representative of this Company called upon a mill owner in an endeavor to interest him in boiler inspection and insurance, but the owner could see no value in such service. About a month later a crack developed in the longitudinal seam of one of the boilers in this mill and a supposedly experienced mechanic was called in. The crack was drilled at intervals, the holes tapped out, and soft iron plugs inserted to stop the leakage. About a week later the boiler exploded, fatally injuring the fireman and seriously injuring his wife who happened to be there at that time. Had this boiler received the attention of of a qualified inspector the dangerous condition could have been pointed out in time to prevent the disaster which occurred.

Mention was made, in the July issue, of repairs to a lap seam crack by autogenous welding. It has been reported to us that a boiler belonging to the Wishkah Shingle Co., State of Washington, was repaired (?) at a lap seam crack by this method and soon afterwards exploded, killing three people. It was said that the boiler was not regularly inspected by a competent person and that the owners had no knowledge of the danger in such a repair.

Many similar instances are recalled of the inevitable sad results which follow improper treatment of a lap seam crack. This type of failure frequently shows itself by a leak extending over a comparatively short distance. The boiler plate may very likely be cracked over a considerable distance but, not being apparent by casual inspection, this is not realized and repairs are confined to the vicinity of the leak. A soft patch is frequently placed over the leak, sometimes temporarily alleviating the leaky condition and at other times accentuating it. Sooner or later, however, the crack extends through the plate at other points and an explosion frequently results.

But the lap seam crack, although a frequent offender, is not the only cause of trouble. Many conditions, dangerous to life and property, are found on the trips of the boiler inspector. Cracks in other parts of a boiler, such as to make it unsafe to use, have often been found. On one such case, cracks twelve and fourteen inches long were found at the bend of the flange on each side of the fire door sheet of a locomotive type boiler and in addition, some smaller cracks in the side sheets, making it necessary to condemn the boiler as unfit for service. A second hand dealer purchased the boiler and sold it to a sawmill in Virginia. A few days after it was put into service it exploded and two persons were killed. In this case the inspector gave protection to the original owner and also did all he could to safeguard the public by warning the second hand dealer not to sell the boiler but to cut it up for scrap. The unscrupulous dealer, however, was not so mindful of the safety of others. A similar case was that of a boiler which exploded, some years ago, near Clifton Heigh⁺ , Pa.

Repairs, that to the inexperienced appear safe, but to the boiler inspector are immediately recognized as dangerous, are frequently found. In one such case a bag had developed in a boiler from overheating which resulted probably from an accumulation of scale. The "repair" made in this case is illustrated in Fig. 1, below. The center of the bag or bulge was tapped and a ⅞″ threaded rod screwed in with the end upset or riveted over. The upper end was supported by a flat iron bar resting on the top row of tubes. The idea apparently was to prevent a complete failure at the bag. However, an excellent place for scale to accumulate was provided by permitting the bulge to remain and the condition presented was rather dangerous. Our inspector had the rod removed. The plate was then heated and the bag driven back, the small hole being plugged with a rivet.

The corrugated furnace in one of two Scotch-marine boilers collapsed and necessitated repairs to that boiler. Thinking it advisable to investigate conditions in the other boiler, a hydrostatic test was applied by our inspector and the furnace showed a decided tendency to collapse, indicating that the structure was weak for the pressure desired. It was recommended that a new furnace be installed and assurance was given that this would be done. A few weeks later the owners requested that we make an examination and this we proceeded to do. The results were rather remarkable. It was found that the repair man who was called in to do the work, after looking over the boiler, and announcing that he could "fix her as good as new," apparently concluded that a cylindrical furnace, lying in a horizontal position, could only collapse from the upper side although subjected to pressure from all sides. He therefore placed four 1½″ rods extending from the upper surface of the furnace, where the furnace had first shown a tendency to collapse, to the top of the boiler shell and then remarked to the engineer, "There she is, she's all yours." Unfortunately for the owner, this repair could not be approved.

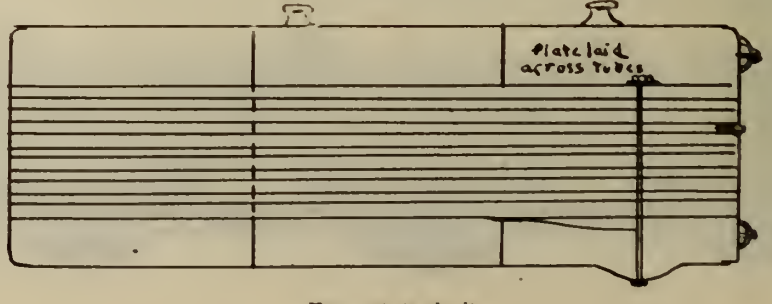
Improper attachment or use of boiler appliances often results in damage to the boiler even if an explosion does not occur. Such conditions are often found and corrected by the boiler inspector. As an example we cite the following:—

One of our inspectors, when calling at the office of a certain plant was advised that considerable trouble had been experienced from leakage at the girth seams of the horizontal water tube boilers in use in the plant. The superintendent stated that they had recaulked the seams a number of times but to no avail and the boiler maker who had done this work had expressed the opinion that they had received a "bum bunch of boilers." On walking into the boiler room the first thing that struck the inspector's eye was that the water glasses were considerably below the drums of the boiler. A comparison of the water level in the gauge glass with the height of the drums showed that the water columns were set 12″ too low so that when the normal water level was carried in the water column there was absolutely no water in the drums. This resulted in rapid overheating as soon as the boiler was fired up. When the water column was correctly placed and the seams again caulked no further trouble was experienced.

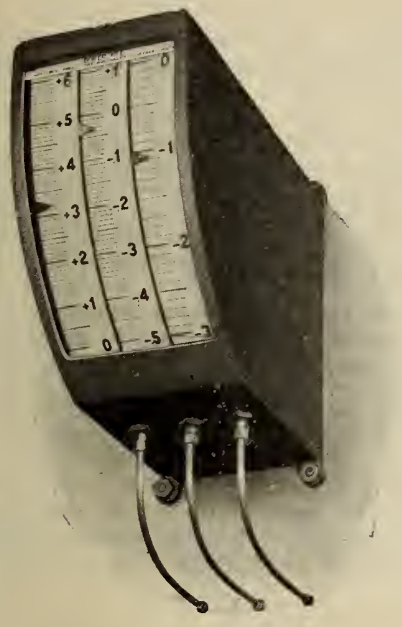
Improper pipe connections are often found. As an example of this condition, the following experience, related by one of our inspectors, will be illustrative.

"As I was going about my regular work I stopped at a small mine and became engaged in conversation with the engineer who claimed he was a licensed man and said that he had installed the boiler plant. He took great pride in showing me the installation but after looking it over I was unable to work up the same degree of enthusiasm that he had and the reason may easily be explained.

"The faulty connection that first struck my eye was that a ½ in. pipe had been run down from the dome of the boiler to supply an injector and a feed pump, both of which required a 1 in. line, and to this pipe the steam pressure gauge had also been attached. The steam pressure, when first noted, was 100 pounds. Soon however, the injector was started and, because of the pressure drop which then took place in the ½ in. pipe, the gauge reading fell back 60 pounds. The engineer noticed this and immediately forced his fire a little harder



How not to do it.



Three Pointer Gauge

Wall Mounting

Multi Draft Readings at a Glance

with the

BAILEY Multi-Pointer

This distinctly new and valuable device gives you **multi** draft readings that can be accurately read at a distance of 20 feet. It shows for easy comparison the draft readings of the Fire Box with the readings for other points. Any engineer will appreciate its immense value as a time-saver and an insurance of absolute accuracy.

It is made to accommodate any required number of separate pointers, ranging from 2 to as many as 12. Two distinct types of casing are used, one for wall mounting as shown; the other for meter board.

If you are having difficulty with draft readings, our circular No. 160 will be of inestimable value.. Write for it to-day!

218

which soon resulted in the safety valve blowing off although the gauge reading did not rise any great amount. Seeing this, the engineer remarked, "sometimes that safety valve doesn't work just right. I don't know what gets the matter with it. I've had it off several times and examined it but I can't find anything the matter with it."

"I stepped outside to look up at the valve which was about twelve feet above the boiler and while looking at it the blowing stopped. A few minutes later I walked in and looked at the pressure gauge. It showed 140 pounds. I immediately started an investigation to determine the reason for the safety valve remaining closed with this pressure behind it and, when I climbed up on the boiler, I soon discovered the cause. There I found a gate valve, closed tight, in the line leading to the safety valve. Apparently the engineer had closed it when I stepped outside for just then I saw him come around to the front of the boiler, glance at the pressure gauge, and then rush up the ladder to open the gate valve. This I cautioned him to do slowly as a sudden release of the pressure on the boiler might have caused an explosion. As soon as a few turns had been given the gate valve to open it the safety valve began to blow and continued to do so until the pressure was reduced to 100 pounds.

"A sketch of the boiler with its improper pipe connections is given in Fig. 2. In addition to what is shown there I might mention that the blow off line had been piped outside the building where a trap had been formed so that any water accumulating in it would freeze very readily. A man, in blowing down the boiler, would have been placed in a very dangerous position.

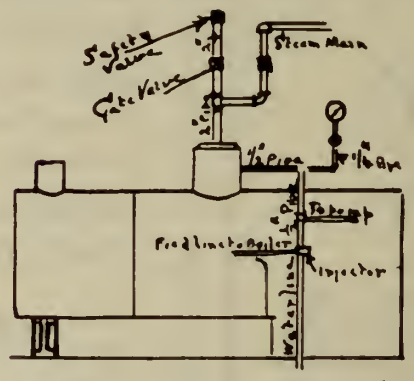
"A short time later I had to make an internal inspection of this same boiler and, although the engineer said that he had just had the boiler open the day before and that I could take his word as to its good condition, I found it to be in very poor shape. Although no great amount of scale was present, a considerable amount of corrosion and a number of cracks in different parts of the boiler were found. When this information was given the superintendent he ordered the boiler out of service."

Inspections are of value not only in the detection of dangerous conditions but also in preventing unnecessary expenditures for repairs. In one case a tube ruptured in a vertical water tube boiler and there was also some slight overheating of several other tubes. The coal mining company who owned the boiler engaged a repairman to put the boiler in serviceable condition. This repairman had them place an order for new tubes which were to cost $1,200. He expected to almost take apart the entire boiler—the total cost to be about $2,500, and had actually started work. Someone, however, suggested to the coal company that they obtain the services of a boiler inspector and at their request we rushed a man over to the plant. As a result of his inspection the repairs necessary were limited to ten new tubes and some other minor repairs, amounting in all to about $250, or a saving to the owner of over $2,000. This was at pre-war prices and the figures would be considerably greater at the present time.

In another somewhat similar instance the expenditure for repairs was reduced from $1,100 to about $20. In still another case a boiler had been condemned, by a steam fitter, as unfit for further use but upon examination by a boiler inspector was found to be good for many years more of service.

The boiler inspector also finds a field of service in the help that can often be given a manufacturer in the arrangement of his steam generating equipment and piping. In a certain plant where rendering tanks were used, considerable difficulty had been experienced in obtaining a lard of uniform quality. Changes that were recommended by the inspector resulted in safer working conditions and a more uniform product.

In another striking instance. which seems almost incredible but which, nevertheless, is true, a furniture factory complained of the wastefulness of their boiler equipment from the standpoint of fuel consumption. After an inspection we recommended the installation of a boiler of a different type. Before the change the plant used a car of coal a month in addition to the refuse from the mill.



Faulty Connections on Boiler.

After the change the coal consumption was reduced to a maximum of two cars of coal per year. It does not require much figuring to compute the saving that would be made in a case like this.

Many accounts might be given of the savings resulting from the suggestions of the boiler inspector, such as the covering of steam pipes, use of pumps and exhaust steam heaters in place of injectors, use of a lesser number of boilers to carry the load, and so forth. We shall content ourselves, however, with the relation of one instance which is interesting from more than one point of view.

One of our inspectors, upon visiting a plant, noticed that the exhaust steam drips were being discharged to the sewer. He made the recommendation that this practice be discontinued and, with the proper piping arrangements, the condensate be returned to the boiler so that whatever heat was contained therein might be saved. The next visit of inspection was made by a different man and the engineer of the plant, in speaking to him of the recommendations made by the previous inspector, said, "Now wasn't he a numskull? Why we had already cooked all the steam out of that water."

It would be practically impossible for the owner of a plant to give the time for a personal inspection of his boilers even though he were so inclined and sufficiently experienced in this line of work. No matter how efficient operating engineers may be in running their plant, but few of them have specialized training to qualify them as inspectors of boilers. On the other hand the expert boiler inspector examines the boilers for all known causes of trouble and then the owner is handed an unbiased statement of the condition of the equipment. If everything is in good shape the owner has a sense of security from accident, or, if there is trouble in sight, ample time is given to make repairs before the danger point is reached.

ELECTRICAL PLANT

A new electric power development will be erected at Great Falls on the Winnipeg river, 63 miles from Winnipeg. It will have a capacity of 168,000 horsepower and will cost about $10,000,000. Announcement of the successful result of financial negotiations was made recently by A. W. McLimont, vice-president of the Winnipeg Electric Railway Company. Work on construction already is under way, with about 200 men employed, but as the work develops between 1,000 and 2,500 men will be engaged.

The undertaking will be carried out under the charter of the Manitoba Power Company, which company is taking over the plant and assets of the Winnipeg River Power Company. Sir Augustus Nanton is president of the Manitoba Power Company, and Mr. McLimont is vice-president in charge of construction and operation. The plant will be constructed in six units of 28,000 horsepower each, and work will be completed in 1924. Promotors of the development believe that the availability of a large quantity of cheap power will do much for Winnipeg's industrial promotion.

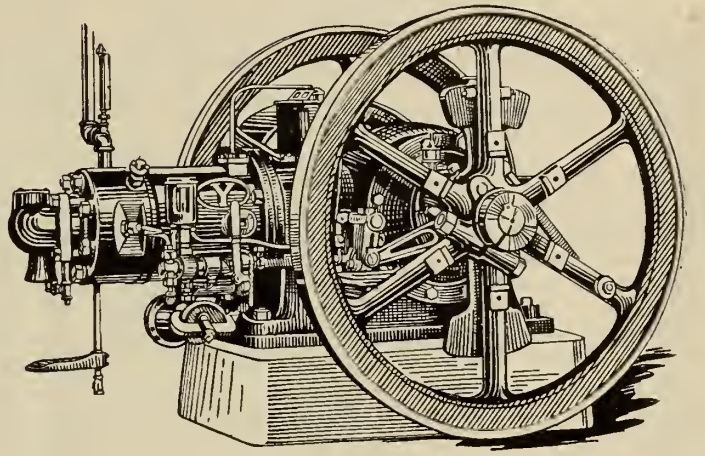
NEW ANTI-FRICTION METAL

There are many special alloys for the purpose of lining the bearings of machinery so as to reduce the friction to a minimum. The objection to most of these is that if from any cause they should become hot the metal melts and runs out. This drawback is avoided in a new metal which has been tested in Great Britain with very satisfactory results. In these tests the metal became very hot without showing any signs of melting, and when forced lubrication was used the bearings showed no sign of wear or flow even with a load of over 1,000 lbs. per square inch.

Reliable power at low cost

Fairbanks-Morse Type "Y" Semi-Diesel Engines are designed to operate on low grade Oil. Some of the special features of this engine are:

Power at minimum cost—Operation practically automatic — Perfect lubrication — Combustion Chamber water jacketed—No hot ball to overheat or burn out—Air tight crank case—Special quick starting arrangement.



The "Y" Engine is made in both horizontal and vertical types and can be supplied in sizes from 10 to 300 H.P. in single units.

This Bulletin Points a Way to Boiler-room Economy

The crying need of the world to-day is ECONOMY —and still MORE ECONOMY—coupled with greater efficiency in production.

There is a host of ways to arrive at the much desired result, of course.

One of them—a tremendous help in reducing boiler-room losses—is the Vulcan Soot Cleaner. It reduces stack temperature, increases steam capacity and production, and decreases fuel consumption.

Send for a Vulcan Bulletin and let it show you how and why Vulcan Soot Cleaners are a vital necessity in the modern boiler-room.

The VULCAN SOOT CLEANER COMPANY

MAIN OFFICE DU BOIS PA. OFFICES IN THIRTY CITIES

The Bulletin shown describes the Vulcan Soot Cleaner for Stirling boilers. Other Bulletins are: No. 541, for B. & W. boilers; No. 547, Wickes; No. 550, Connelly, Badenhausen and Erie City Vertical; No. 552, Edge Moor; No. 556, Keeler, Geary and Union; No. 534, Return Tubular.

Beveridge Supply Co., Ltd., MONTREAL.

PUMPING STATION FOR MONTREAL WILL BE MODERN IN EVERY RESPECT

MONTREAL is growing. In fact is growing so rapidly that its present water supply service has to be increased again. As the city has grown, additions to the water supply have been made, but during the last year the water consumption increased two million gallons per day. The capacity of the Point St. Charles low level pumping station has been increased several times, but the later additions include electric driven turbine pumps. In the old pumping station are three of these units. There are two units each of thirty million gallons per day capacity, and one of twenty millions. One of the larger is a De Laval pump, and the other a Worthington. Both are driven by Westinghouse motors. The smaller pump is a Mather and Platt, driven by a Canadian General Electric motor.

Together these pumps have a daily capacity of eighty million gallons. During the hours of peak load however, they cannot take care of the city's requirements, and steam units are thus daily called into service. After due consideration it was decided to build a new pumping station as the old one had been enlarged to a point where it was neither practical nor advisable to go farther.

The new station is located a short distance from the old station, and very close to the filtration plant. The water is taken from the St. Lawrence River at a point some distance up the river and is conveyed to the pumping station by means of an aqueduct. Almost twenty-five feet of lead is obtained and some three thousand horse power can be developed, if desired, from the water passing through the aqueduct without increasing the velocity beyond that which is necessary to carry away any sediment and thus prevent the gradual filling up of the aqueduct. The present lining of the banks is designed for water supply only and not for power purposes. At present all water passes through the filtration plant and experiments have been conducted, the results of which, lead the engineers of the Montreal Water Board to believe that the capacity of the filtration plant can be so increased that the requirements of the city can be taken care of for several years to come.

The new station is to be the best equipped and most elaborate of its kind in Canada and one of the most complete on the continent. It will have a capacity of three hundred million gallons per day, divided in two similar wings, each having a capacity of one hundred and fifty million gallons per day and situated symmetrically about a central control portion of the building. It is only proposed to build one wing and the central control section of the building at this time. The wing will contain six pumping units of thirty million gallons capacity a day. As one unit will be always held ready as a spare the nominal capacity will thus be one hundred and fifty million gallons per day.

The building will contain its own machine shop, the executive offices of the Montreal Water Board, and one section will contain the transformers, oil switches, etc. The feature however, is the central control. One man will be able to operate and control every unit in the station. Besides, the operator will be so advantageously located that he can see every part of the room where the motors and pumps are located. In addition a very complete signalling system is installed, similar to the marine telegraph used by ship's officers on the bridge of a vessel to communicate with the staff in the engine room. The feature of this, is that every order is confirmed by the man receiving it before it is executed.

Rarely has it been the privilege of the writer to see an installation where greater care and thought have been exercised to prevent a breakdown from either electrical or mechanical failures. The electricity is received from the power company in two towers each quite separate from the other and both distinctly apart from the pumping station building. Here lightning arrestors and other protective apparatus are found. Several separate underground lines lead from the towers to the transformers. All equipment is of generous proportions and amply protected. Throughout, duplicate installations of leads, switches, etc., are found, and where there is any chance of even a temporary tie up, triplicate and quadruplicate installations are made. No risk from hot contacts in switches are taken. All equipment is spaced well apart so that a "short" or fire in one piece of equipment will not in any way jeopardize another. Mr. Chas. Des Baillets of the Montreal Water Board had charge of the design of the building, and the selection of equipment. Great credit is due him for the precautionary measures he has taken to prevent a breakdown in the equipment.

Each pump discharges at 95 pounds pressure into a 36 inch pipe, thence through a Venturi meter into a large 72 inch main. The contract for the building was recently let to the Atlas Construction Company of Montreal. Work is being started immediately and will be rushed to completion. The first pump will be operating in the new station in September 1922. Power is taken from the Montreal Light, Heat and Power Company which Company has transmission lines from Shawinigan Falls, Cedars Rapids, Soulanges, Chambly, and Lachine, all hydro electric power, and also from the steam driven plant at Ville La Salle.

OIL TESTING SERVICE

The Westinghouse Electric & Manufacturing Company has established an oil testing service wherein operators can mail samples of insulating oil to the Westinghouse works for test. It provides a thoroughly dry bottle, a safe mailing container, which when received at the works allows careful testing by experienced men and a prompt report of test results. This fills the needs of many power plant operators who have no good method of telling whether or not their transformer oil is in perfect condition.

Considerable thought has been given to the development of this service, with the idea of making it simple for the operator to handle and give him a prompt report as to the condition of the oil. After drawing the sample the operator seals, packs and mails the bottle to the Engineering laboratory at East Pittsburgh. To make this part of the work easy, an instruction and order sheet and a printed return label have been provided. The instructions cover the taking of the sample and its proper preparation for mailing. The label carries an envelope in which the operator can enclose his order covering the work of testing. As soon as the test is made, a report of the condition of the oil is returned. In case the oil is not in first class condition, suggestions as to treatment are given.

ABSOLUTE ZERO OF TEMPERATURE

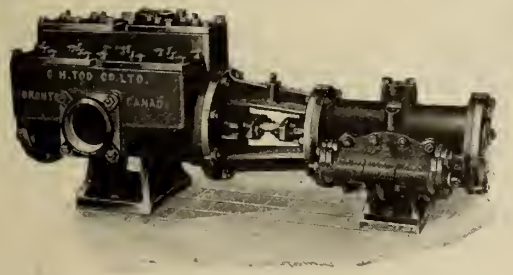
A simple explanation of the method arrived at in finding absolute zero of temperature is as follows. If we take for example 493 cubic inches of hydrogen, oxygen, or air, at a temperature of 32 degrees and keeping them at constant pressure, not necessarily the same for each, heat them so that their temperature is raised one degree, and their volume has increased by one cubic inch, so that now it is 494 cubic inches. If we again raise them another degree of temperature we find that the volume has increased again one cubic inch, being now 495 cubic inches. If we cool the gas instead of heating it we would find that with each degree of temperature decrease we should have a decrease of volume so that if we cool the gas to zero, we should decrease the volume by 32 cubic inches, making it 461 cubic inches. Now if we were to keep on decreasing it is obvious that when we had reached the zero of volume we would have reached the absolute zero of temperature, which would be at 461 below zero on the Fahrenheit scale. The same reasoning can be applied to the Centrigrade scale, except that in this case the volume at freezing point or zero on the Centigrade scale would be 273 cubic inches, and the absolute zero of temperature 273 degrees below zero or freezing point on this scale.

HEPBURN

Reliable Products

THIS VERTICAL RAM FEED PUMP is a strongly constructed outside packed type for Feeding Boilers carrying the highest steam pressures. Every part is accessible, and it takes little floor space in the Power House.

HAND OVER HEAD TRAVELLING CRANES —Single and double I Beam Types, in capacities from one-half to twenty tons.



Our lines include Vertical Engines, Compressors, Winches, Cut Gears, Derricks, Cranes, Pumps for every purpose, Hydrants, Blacksmith Work, Valves, Grey Iron Castings and Acetylene Welding.

The HEPBURN VACUUM PUMP—a self-draining type with the steam chest located on the side of the cylinder. Long strokes—long life

Would You Buy a Trap That MAKES Condensate

Judging by the size of many steam traps, they were made to **promote** condensation rather than to take care of it. Traps of the "bucket" and "float" types in particular become regular steam condensers by reason of their great internal area and the large volume of water they hold. Both of these factors cause the formation of **extra condensate!**

This waste of heat units—and remember, **heat units mean coal**—is positively prevented by the use of

STEAM TRAP

SARCO

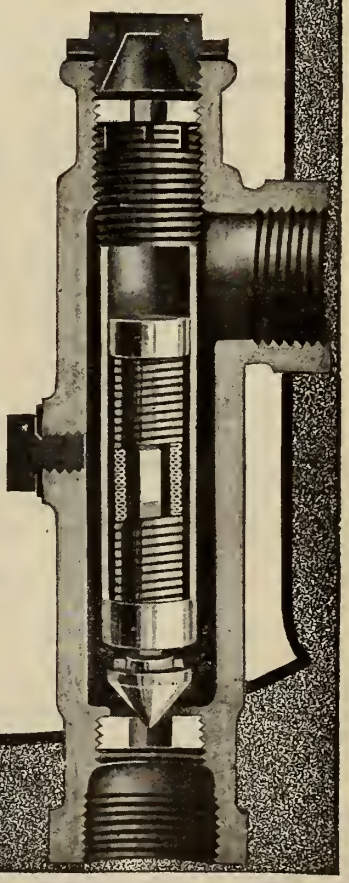
Small in size, and having neither steam dome nor reservoir, the Sarco offers no opportunity for a lot of condensate to form. No chilling walls, no big body of water to reduce **the steam in the trap** to liquid.

As soon as a little water collects, the Sarco opens promptly and drains off the condensate.

All the steam from the lines above passes on. No part of it remains in the form of condensate, to surrender its heat. No live steam can escape.

Don't use steam traps that deliberately rob you of heat units. Install the scientifically constructed Sarco. It is a valuable conservator of coal.

The Steam Trap Sarco costs only one-third as much as high-priced, expensive - to - maintain traps. And the cost of installing is nil. For it can be quickly screwed into the pipe line at any angle. No need to dig a pit nor build a platform. Let us send you a Sarco on 30 days' free trial.



There's Steam Trap information in our Sarco Book J-21. Write for a copy today.

Dayton-Dowd Centrifugal Fire Pump

Arranged with dual drive consisting of electric motor and auxiliary gasoline engine. Capacity 500 gallons against a head of 100 lbs., speed 1,450 R.P.M.

DAYTON-DOWD Fire Pumps

Install them for a reliable standby to meet any emergency.

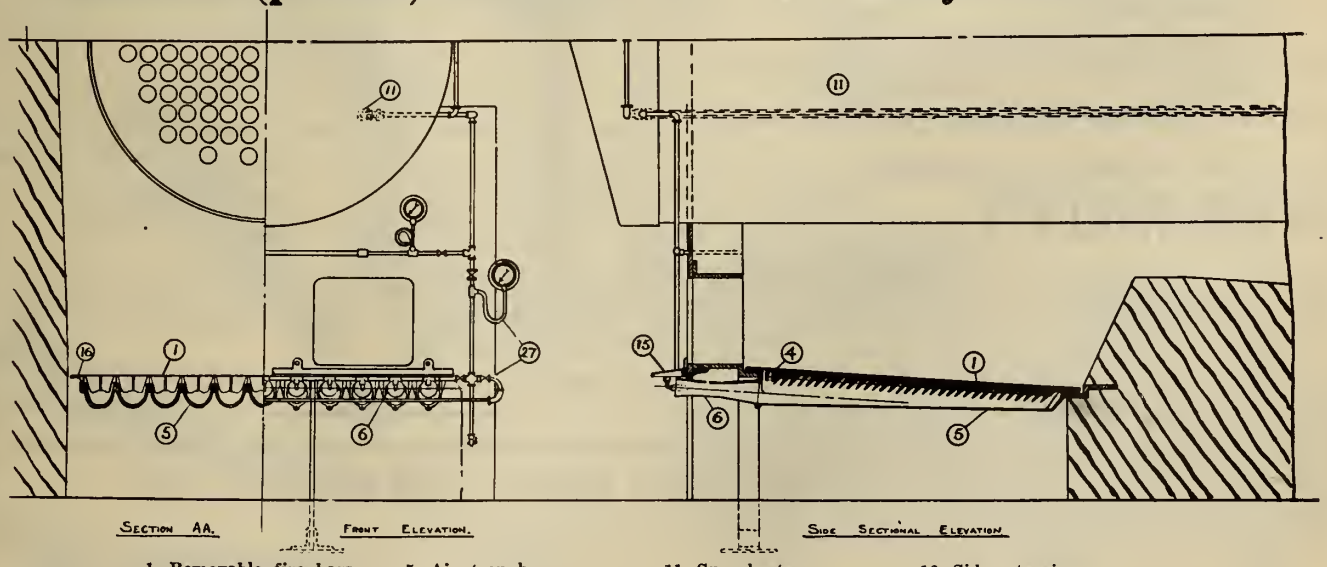
The double drive (consisting of electric motor or turbine and gasoline engine, one on each side of the fire pump as shown above) is a convenient method of installation and affords perfect dependability in case of electric or steam power failure.

This installation is approved by the Canadian Board of Fire Underwriters. Write for bulletins of Dayton-Dowd Pumps for every service.

THE ARTHUR S. LEITCH COMPANY Limited

1001 - 2 Kent Bldg. Toronto, Ontario

Turbine (patent) Furnace for Externally Fired Boiler



1. Removable fire bars. 5. Air trough. 11. Superheater. 16. Side extension.
4. Locking bar. 6. Air injector. 15. Ash guard. 27. Steam fittings.

Also supplied for internally fired boilers. Write for particulars of the performance of the Turbine (patent) Furnace—using coal slack or coke dust. If you have cheap low grade fuel available let us furnish you with full information at once. Over 1,100 of these furnaces are giving satisfactory service in Britain now.

Manufactured by:

The Turbine Furnace Co. Ltd. London, England

Sole Canadian agent:

PERCY A. GOEPEL, 525 Pender W. VANCOUVER

TECHNICAL COURSES

NOVA SCOTIANS — SPECIAL ATTENTION. The Technical College now offers new Correspondence Courses in all subjects important to men engaged around power house plants such as Steam Engineering, Blueprint Reading, Use of Slide Rule, Shop Mathematics, Mechanical Drawing, Practical Electricity, Electric Wiring, Gas and Oil Engines and many others.

Cost per course from $6.00 to $14.00.

Write for full information to Technical College, Halifax, N. S. P2H

SITUATIONS WANTED.

STATIONARY ENGINEER DESIRES POSITION as engineer or fireman. Holds second class certificate, 20 years experience. Apply to Box 151121, Power House.

Answers will be given freely to subscribers to MacLean's Magazine in regard to industrial investments (if a stamped addressed envelope is enclosed) by addressing Financial Editor, MacLean's Magazine, 153 University Avenue, Toronto.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS WANTED—MALE

ENGINEER—HOLDING ONTARIO CERTIFICATE, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821, Power House. p.2.h.

INSTRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any province, stationary or marine. Terms and particulars on application. Box 13921, Power House. Ph2

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House, P2H

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

FOR SALE

Two 72" x 18' HRT Boilers complete with stack and breeching good for 130 lbs.

One Tandem Corliss Compound Engine Cylinders 14" Stroke 26" x 36" driving wheel 14' x 25" face. 270 HP with 125 lbs. steam pressure. Floor space 31' x 12' with two injectors and Smart Turner Pump. Price $7,500.00. f.o.b. cars, province of Quebec.

EMPLOYERS! BUSINESS MEN! EMPLOYEES!

What Can We Do For You?

Here's what we have done for others:
Sold machinery and power house equipment of all kinds.
Brought together employers requiring men to fill positions, and employees seeking positions.
What we have done for others, we can do for you.
Our classified rates are as follows:
2 cents per word, with a minimum charge of $1.00 for fifty words or less.
Secrecy is secured by using a box number, which counts as five words.
This is your department of service and we can help you if you give us the opportunity.

"Canada's Next Premier"

No matter which he is—all three possibilities are pen-pictured in

November 15 MacLean's

"Scrutator," a writer of rare analytical power, holds the mirror up to Meighen, King and Crerar. Each of the three is "called up" in printers' ink as true to life as if they stood there separate and distinct in flesh and blood. It is one of the most searching, masterly articles ever written with public men as subjects. It is fair to each—and nothing more; a cold-blooded analysis of the virtues and weaknesses of the candidates in turn. It will surprise you, startle you, tantalize you with its subtleness and depth.

"Funny Thing That Tariff"—by J. K. Munro. This number of MACLEAN'S has four timely articles dealing with Big Politics, the whimsical observations of J. K. Munro are, as usual, full of amusement as well as information. Munro just can't help seeing the funny side of politicians and politics. Of Ottawa and Parliament Hill he makes a sort of continuous vaudeville performance. He gets some big laughs out of election activities.

Lt.-Colonel John Bayne MacLean

has been a watcher from the hilltops longer than most of the present-day school of Canadian writing men. As usual, in his article on the Dominion political situation in November 15th, issue of MACLEAN'S MAGAZINE, he strictly maintains the detached attitude of the true journalist. But in his survey of the field and the political gladiators there is a warmth and an intimacy with both the men and the situations that could be imparted only by one who has long been a close and observant student of governments both Dominion and Imperial. This article appears under the caption—

"All Three Are Good Men."

"Our Election Enigma—Women!"—by Agnes C. Laut. How are they going to vote? Are they going to vote at all? Are they going to realize citizenship? These are some of the potent questions asked and answered by one of Canada's leading women authors—Agnes C. Laut. What influence will woman with her vote bear on Canadian politics? Will the woman wage-earner join the ranks of labor when it comes to the battle of the ballots? There is a fund of information for both men and women readers in this right-on-the-minute summary of Miss Laut's.

Other Gripping Features in This Issue:

If you like red-blooded fiction with the tang of the race track in it, W. A. Fraser's short story, **"The Thumb Print,"** is sure to satisfy. It's a case of a pair of sleek double-crossers being neatly double-crossed by what they deemed a rich doubble-crosser.

"Whose Bride Was Mary," is a delightful, fast-reading short story of perplexing situations from the pen of Ethel Penman Hope.

The first of Rev. R. G. MacBeth's thrilling articles on old days with the Mounted Police, "Policing the Prairies," is given complete in this issue. Learn how the Mounties first invaded the prairies in the days of Indian scalp-takers and white "bad men," and in the face of tremendous difficulties.

Incidentally there are two generous instalments of the serials, "Mostly Sally," by Pelham Grenville Wodehouse, and "The Yellow Streak," by Valentine Williams.

What do you know about "Relativity" and the Einstein Theory?—An illuminating summary of Sir Oliver Lodge's explanation of it is one of the many interesting topics dealt with in MACLEAN'S "Review of Reviews."

"Food Facts You Should Know," by William Fleming French, and the regular departments devoted to Finance, Current Humor and Women and Their Work, complete a number bristling with good things.

From Floor to Roof——

Perfect Plant Protection

ROOFS, VENTILATORS, SKYLIGHTS AND EXHAUST SYSTEM BY GEO. W. REED & CO., LIMITED.

"REED" SPECIALTIES

Mill Floors.

Almetl Fire-Doors.

Shur-Pull Exhaust Systems.

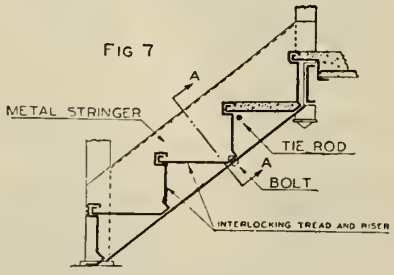
BOIS PATENT Stairs.

Anchor Bar Skylights.

Burt Ventilators

The Standard Specifications of Engineers and Architects

for the past seventy years have called for the "REED LINE" from cellar to roof—REED Special Mill Floors, Shur-Pull Exhaust Systems, Almetl Fire Doors and Shutters, Anchor Bar Skylights, Burt Ventilators, REED-CLAD Roofs.
REED installation means:—protection against fire loss; healthier, happier employees; greater production; increased plant value.



SECTION OF METAL STAIRS

Ask us about "BOIS PATENT" Interlocking Steel Stairs. Patent interlocking feature eliminates bolting treads to risers. Absolutely fireproof.

We also do all kinds of sheet metal work.

Floors That Last!

Decayed and rotting floors are a menace to any plant. They spread disease, cause accidents, hinder production. "REED" Special Mill Floors are absolutely damp, rot and vermin proof. They are built to stand the constant jar and vibration of heavy machinery. Now is the time to get your old floors replaced.

Our Engineers will be glad to co-operate with you. Write us.

An Efficient, Low-cost Combination!

Mason Standard Reducing Valve Iron Body

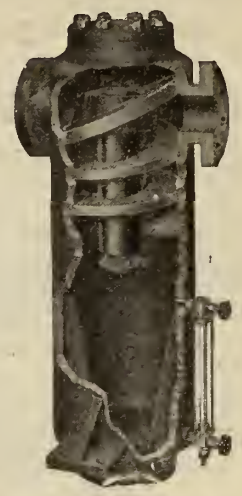
Mason Valves

Mason Standard Reducing Valves reduce and maintain an even pressure of steam or air regardless of the variation of the initial pressure or of the volume of steam or air required. A special socket key permits them to be set to constantly maintain any required pressure within a wide range. Made in bronze for pressures from 5 to 300 lbs. In iron for pressures up to 180 lbs.

Write to our nearest branch for particulars of these or any other specialties in which you may be interested.

Stratton Separators

Where a thoroughly reliable and always dependable Steam Separator is required, the **Stratton** fills the bill! It is of the centrifugal type and thoroughly eliminates moisture without adding back pressure. Is simply constructed with large receiver capacity.



Ashton Pressure Gauges

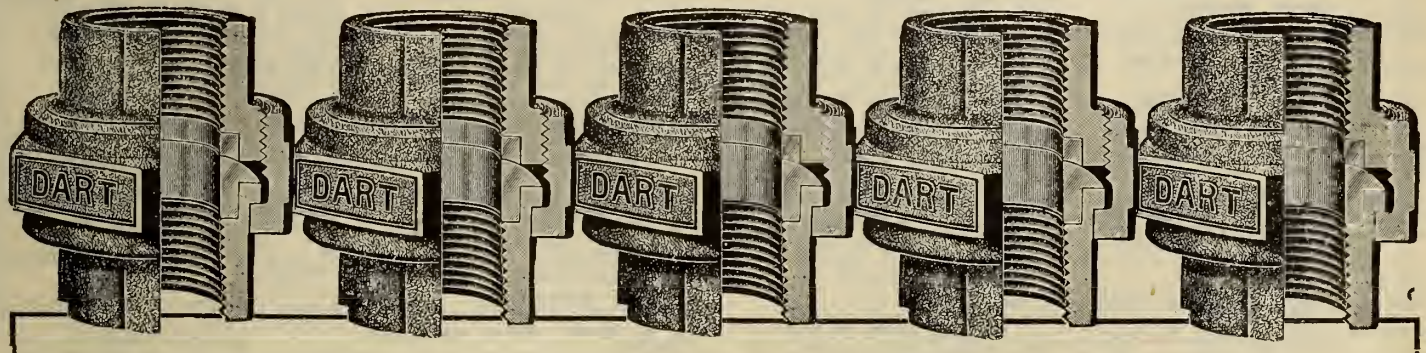
Made in many designs for air, gas, etc. **Hand graduated** to insure absolute accuracy. Rigidly inspected.

The Mason Regulator & Engineering Co.,

LIMITED

135-153 Dagenais St., **MONTREAL, QUE.**

Agencies at: **TORONTO, Halifax, St. John, Winnipeg, Vancouver**



Dart Unions are a Permanent Investment in a Pipe Line

The Bronze to Bronze feature eliminates all possibility of deterioration at the vital part. Bronze will not rust or corrode.

Iron Parts are Extra Strong. They will not stretch or pull apart under strain or heavy pressure.

Never scrap Dart Unions—use again—they're always efficient.

Stop Your Firemen Wasting Coal

and secure

Real Boiler Efficiency

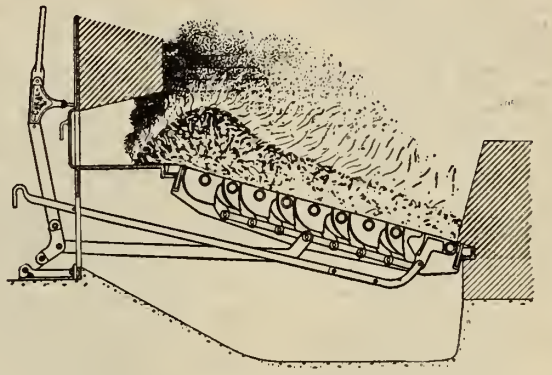

FIG. 1

FIRING

The COKAL SELF-CLEANING HAND STOKER

automatically insures better boiler room conditions and combustion practice. No more hot boiler fronts—no more disagreeable fire cleaning with its inrush of cold air and heavy fuel loss—always ready for peak loads—ash pit losses reduced to a minimum—smoke elimination, and less soot on the heating surfaces—contented firemen and increased efficiency prompted by better boiler room conditions.

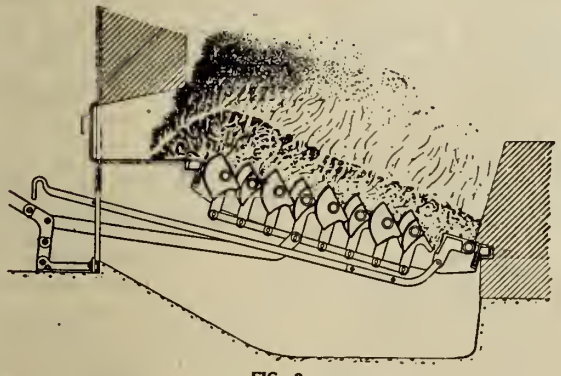

FIG. 2

STOKING

No. 1 **The In-Rush of Cold Air During Cleaning Periods** drops the steam pressure, lowers the furnace temperature and causes heavy boiler strains. Exhaustive tests show that 100 to 200 pounds of coal per boiler are lost "Fighting the Fires" at cleaning time.

No. 2 **Heavy Ash Pit Losses** are caused by the hand cleaning of fires and the extravagant shaking grate. Analysis of your ash pile will show you a fuel loss of all the way from 3 to 12%. Will you stop it?

No. 3 **Smoke During Cleaning Periods** and at other times during operation keeps the Smoke Inspector knocking at your door, you can make a friend of him if you want to.

No. 4 **Your Main Boiler Room Problem today is the human element,** and the use of unnecessary fuel, through incomplete combustion caused by out of date furnace equipment.

No. 5 **Remember, 5 per cent. increase in boiler efficiency,** an additional pound of water evaporated per pound of coal sometimes means the difference between profit and loss.

Are You Getting What You Pay For?

Every power plant in the country is paying for superheating.

If boilers are not superheater-equipped the operator is paying for superheating in the coal he wastes. And he is not receiving the many established advantages derived from a properly designed superheater.

With Elesco-equipped boilers the operator gets not only what he is paying for—highly efficient superheating—but also receives a return in the form of fuel saved or increased capacity, or both.

The Elesco saving of 10 to 20 per cent. of the coal ordinarily burned under the boilers pays for the average Elesco Superheater installation in a few months.

An outline of your power equipment, requirements and conditions will bring definite recommendations regarding the Elesco equipment you should have—and for which you are now paying in one form or another.

PUMPS

This Japanese Waterwheel depended entirely upon human foot power

The ancient waterwheel (here pictured) was used in irrigating Japanese rice fields. All day long the coolies treaded the paddles, setting up a current which forced the water into the fields. It is said that these patient coolies often worked themselves into a "trance."

You can depend upon American-Marsh Pumps for faithful, untiring service. They possess the most modern improvements, and are built to solve difficult pumping problems.

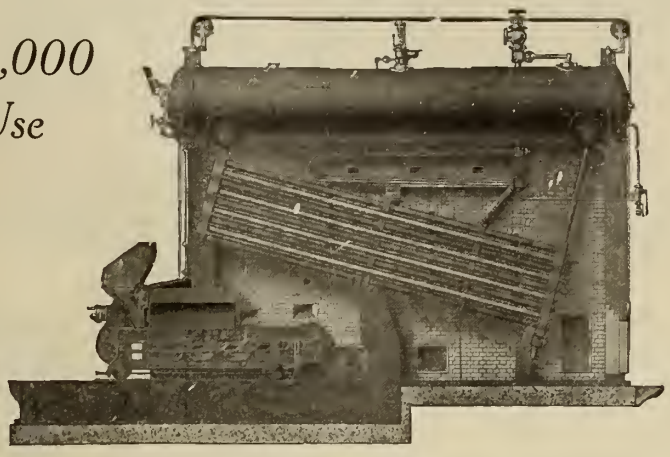
HIGHEST ECONOMY, SAFETY, DURABILITY

Over 50,000,000 H. P. In Use

Coal-Handling Machinery



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

Steam Superheaters

Mechanical Stokers

THE "B & W"

Marine and Land Type

Steam Boilers

Electric Cranes

Piping, Feed Water Heaters

In practically every country of the world, ashore or afloat; wherever there is steam used more than 50,000,000 H.P. of "B & W" Boilers are taken as the standard of all that a boiler should be.

50,000,000 H.P. Think of the colossal magnitude of these figures. Taking a rough average of 250 H.P. would disclose the amazing figures that 80,000 "B. & W" Boilers are in use. **There may be more.**

Naturally, a boiler such as this must have many imitations. But the single fact remains that the durability, safety, and all round economy of "B. & W" Boilers represent to the user to-day, as they did scores of years ago, a monetary value unsurpassed anywhere.

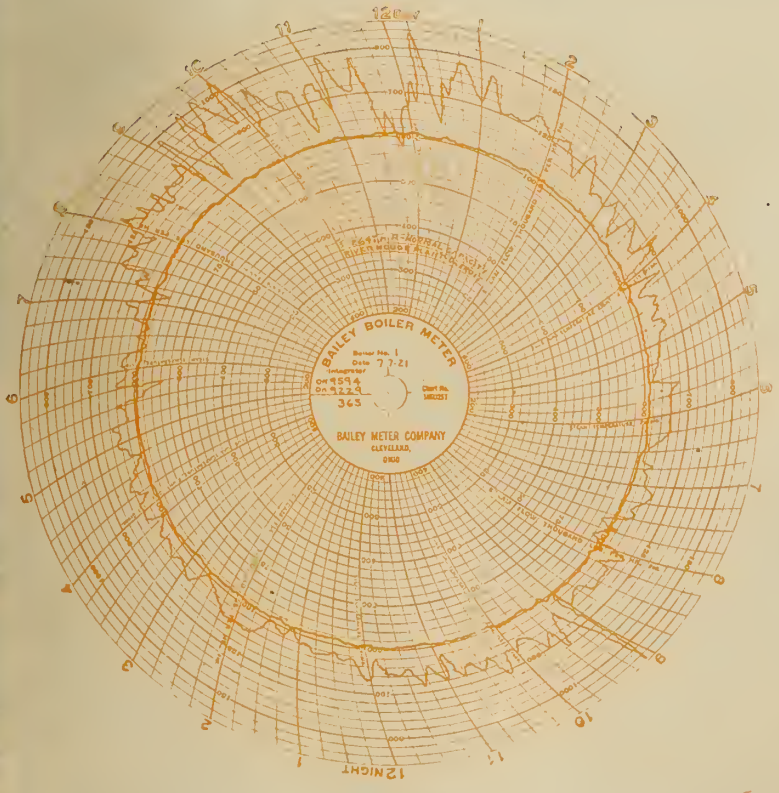
Constant Steam Temperatures Maintained with Elesco Superheaters



AT THE

Ford Motor Company River Rouge Plant

THE maintenance of superheated steam temperatures nearly constant under a wide range of boiler loads is impressively shown on the chart taken from one of the 2,647 H.P. vertical boilers at the River Rouge Plant of the Ford Motor Co.

The outside irregular line indicates the steam flow which under normal operation at 100% boiler rating is 82,586 lbs. per hour. It will be seen that this varies from 163,000 lbs. maximum 197.5% rating to 84,000 lbs. minimum 101.6% rating.

The even inside line indicates the steam temperature. At normal pressure (225 lb. Gage) the approximate temperature of 200° superheat is 600° F. It will be noted that the variation in steam temperature is very slight, being

615° maximum 2.5% above normal
to 588° minimum 2% below normal

or a variation from maximum to minimum of but 4.5%.

Correct design and proper location of Elesco Superheater units in the gas path reduce variations in superheat to a negligible quantity.

Mechanical Perfection Means Profit Protection

The reasons why Bowser Oil Handling Equipment stores oil economically and safely are shown in the above drawing of the Fig. 64.

The Tank, being riveted and soldered from inside, is absolutely and permanently leak proof.

The Pump is rapid in action and equipped with mechanical measuring stops. A liquid test before shipping assures accuracy.

A permanently tight tank avoids lóss from leakage—it prevents contamination of oil, and keeps the oil room clean. Thus cleanliness is stimulated on the part of the employee.

The Piston-Type Measuring Pump quickly and accurately delivers any desired quantity directly into the receptacle. This prevents overflow of oilers—saves time and oil.

Write for Illustrated Booklet C-21. Bowser Equipment is MADE IN CANADA by

S. F. Bowser Co. Ltd., 2168 Fraser St., Toronto, Ont.

BOWSER
ESTABLISHED 1885
PISTON-TYPE MEASURING PUMPS

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

DART UNION COMPANY Limited, Toronto

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

40 to 50% Saving on Labor and Steam

DIAMOND VALV-IN-HEAD SOOT BLOWERS

Cost of labor and steam are two important items in soot blower operation. Note how the Diamond Valv-in-Head cuts these costs in half:

Important mechanical features of the Diamond Valv-in-Head Soot Blower are: Monel metal valve, seat and disc; full floating construction permitting movement of the unit in any direction; control of speed through reduction gearing; ease of operation due to ball thrust bearings, etc., etc.

LABOR (a) The total time required for blowing is cut squarely in two.

(b) There are no lost steps and no lost time between opening of valve and operation of unit.

(c) Only one man is required, no matter how large the boiler. (With other types of blower heads two men are customarily employed on large boilers.)

Under these conditions the cost of labor for cleaning boilers is comparatively small.

STEAM (a) Steam jets are revolving throughout the entire blowing period.

(b) Speed of rotation is controlled by gear reduction. No waste of steam occurs as the result of too slow or too rapid operation.

(c) Globe valves, essential to other heads, require many valuable moments to open and close, during which steam is wasted. The automatic operation of the Valv-in-Head eliminates losses.

The saving in steam with the Valv-in-Head is pronounced, because every bit of steam does effective work in cleaning the boiler.

These are only two of eleven important advantages of Diamond Valv-in-Head soot blowers. Others include savings in pipe, valves and fittings, maintenance, gain in cleaning efficiency, etc., etc.

Every boiler needs a mechanical soot blower and you will save money by buying the best. Ask for your copy of Bulletin 287 describing the new blower.

DIAMOND SPECIALTY COMPANY

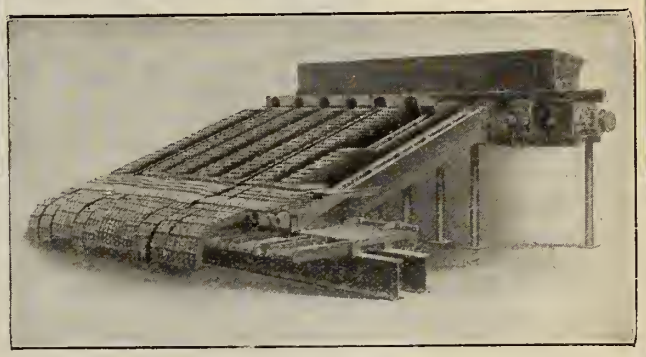
Diamond

SOOT BLOWERS - SAVE 4 to 8% FUEL

RILEY UNDERFEED STOKERS



View of partially assembled Riley Underfeed Stoker

Unusually Low Maintenance

It was fifteen months after the Stokers were started before any replacements were required at the Parkers Wharf Power Station of the Union Street Railway Company, New Bedford, Mass., except for shearing pins. This installation consists of four six-retort stokers firing 500 H.P. boilers and was put in operation during the spring of 1919. Considering the conditions under which a stoker must work, this indicates good operation and sturdy stoker construction.

But you can expect low maintenance from the Riley—it is built for hard service.

The Riley has moving grates; these keep the fire from holes and the grates evenly covered with coal, preventing burnouts.

The safety shearing pin in the connecting rod of each retort effectively prevents foreign matter from damaging the stoker.

When considering stokers, don't think of the first cost alone, maintenance is an important item.

Send for catalog HM-12 and see how the careful design and construction of the Riley Stoker are keeping maintenance to a minimum in the many plants where they are installed.

SANFORD RILEY STOKER COMPANY
Worcester, Mass.

New Truths and Old Fallacies

ATOMIC VOLUME

Some years ago Professor John Goodman was puzzled to account for the wide difference in frictional co-efficients of alloys of the same composition, tested under similar conditions, which led him to investigate this matter. By having alloys analyzed, he discovered that the presence of impurities of low atomic volume caused the difference and naturally the freer an alloy was of such impurities, the lower the frictional resistance.

The atomic volume of a metal is obtained by dividing the atomic weight by the specific gravity. Below we give the atomic volume of the metals used in babbitt alloys and also of those that would be harmful and classed as impurities, when found in such alloys, viz.:

Elements	Atomic Volume
Lead	18.2
Antimony	17.9
Tin	16.3
Arsenic	13.2
Aluminum	10.6
Zinc	9.1
Copper	7.1
Iron	7.1
Manganese	6.9
Nickel	6.7

All of our experience in this connection confirms the accuracy of Professor Goodman's deductions and justifies the care that we have always observed in the selection and cleansing of metals used in Magnolia, and steering clear of these elements of low atomic volume.

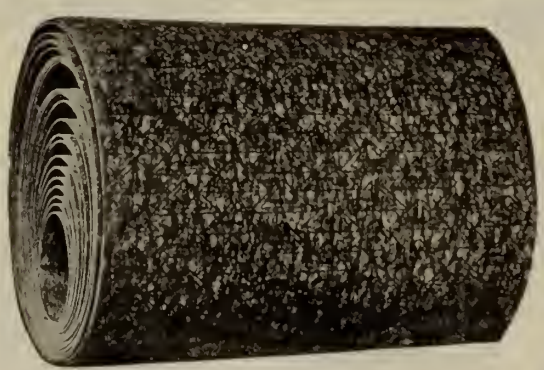
Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.



Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

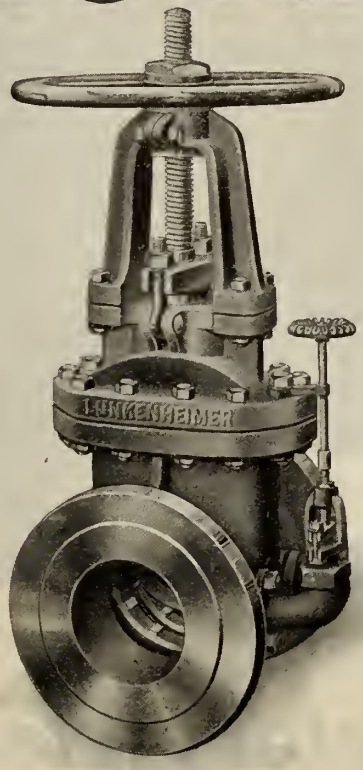
LUNKENHEIMER

"Victor" Gate Valves



Dependable performance is the service record of LUNKENHEIMER "VICTOR" Gate Valves. The "VICTOR" solid wedge disc, double-faced and guided in its travel, is the most practical design of Gate Valve construction. It eliminates "dragging" across the seatring faces and the consequent wear prevalent in valves employing loose parts.

Highest quality materials, coupled with the LUNKENHEIMER method of manufacture; bearings bronze bushed to minimize wear; the indestructible gasket between the bonnet and body flanges and all parts, including the seatrings renewable, all tend to enhance their value and insure longevity.

Made of Iron, bronze mounted, in both Inside Screw Stationary Stem and Outside Screw Rising Stem types, in four weights for pressures ranging from 100 to 250 pounds. Also in Quick-opening Sliding Stem type for pressures from 125 to 50 Pounds, depending on the size.

"VICTOR" Gate Valves are also made in Bronze for pressures up to 250 pounds, and in Cast Steel for pressures up to 350 pounds and temperatures to 800 deg. F.

Specify LUNKENHEIMER "VICTOR" GATE VALVES and insist on their installation. Distributors of LUNKENHEIMER Products situated in every commercial centre.

Vulcan Soot Cleaner installed in a 313 H.P. Oil Burning Goldie & McCulloch Boiler. Imperial Oil Co., Regina, Sask.

For the Sake of Economy

Vulcan Soot Cleaners are a necessary part of the boiler equipment now that Economy has once more become the guiding star of business.

They lower stack temperature—increase steam capacity and production—reduce labor cost—save between 4 per cent. and 8 per cent. of the total fuel consumption—and do twice the soot cleaning that is possible with the hand lance.

There is a Vulcan Bulletin describing the Cleaner especially designed for your Boilers. Let us send it to you. Address any of our offices.

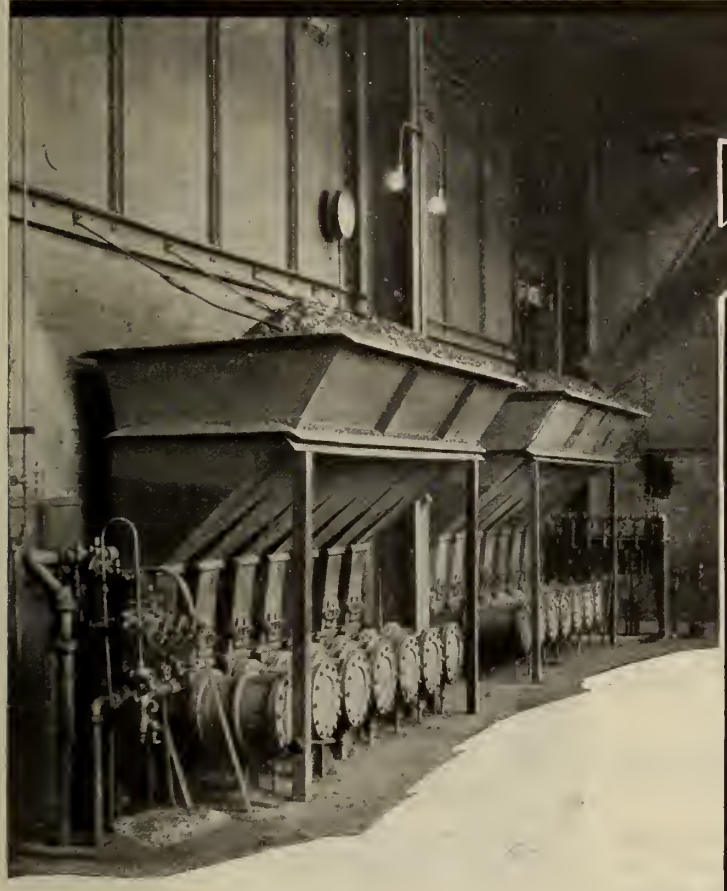
JONES STOKERS



POWER interruptions will not, and should not, be tolerated in modern plants. That is why Jones Stokers are favorites for plants of practically every size. Their rugged simplicity makes shut-downs for repairs next to impossible. Fuel and air are automatically controlled; little attendant labor is required.

In the "A-C" (Automatic-cleaning) type, fires are automatically cleaned.

Retorts may be individually controlled —an exclusive feature.

Clinkers do not form on bridge or side walls.

The under-feed principle of combustion (originated in Jones Stokers) insures maximum economy of fuel at all loads.

These, and other distinctive features that make the Jones Stoker "pay for itself—then pay dividends," are covered by the new catalog.

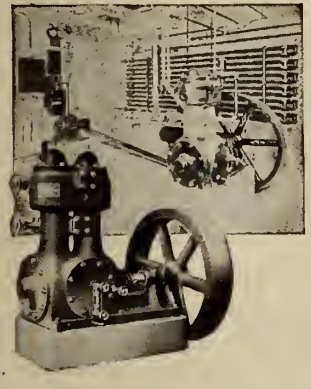
A YORK MACHINE DOES NOT REQUIRE A SKILLED OPERATOR



DON'T get the impression that Mechanical Refrigeration means complicated apparatus, difficult to understand and costly to operate. You need have no such fears if it's a YORK installation.

A York plant is the embodiment of simple efficiency. No skilled attendant is required. One of our customers says in testifying to the simplicity of his York plant, "It is being operated successfully by an employee who, prior to the installation of the machine, had never seen one nor had any experience in operating one."

Constant attention is unnecessary. The simple regulation of one valve gives any degree of cold you want—freezing, zero, below zero—whatever your business needs may require.

If you want the simplest, most efficient, most economical refrigerating system, you will investigate the York Refrigerating Plant.

P⊗H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

P⊗H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

There *Is* a Difference

NONPAREIL Corkboard is pure corkboard—100% cork. But it is more than that. Nonpareil Corkboard is pure cork in screened granules of the proper size, thoroughly cleaned of all dust and dirt. Compressed to exactly the right density, it is baked at a temperature accurately gauged to liquefy the natural gum and yet to avoid charring. Nonpareil Corkboard is trimmed to clean straight edges and corners and to unvarying uniformity in length, width and thickness and carefully sorted for defective boards.

Samples may look like it and names may resemble it, but Nonpareil quality is to be had only in Nonpareil Corkboard. That quality is the result of experience and workmanship and is your guarantee of highest insulating value, maximum moisture resistance and longest life in service.

One of the general storage rooms, insulated with Nonpareil Corkboard, in the plant of Noel & Company, Nashville, Tenn.

For your safe guidance in the insulation of all kinds of cold storage rooms, ask for the 152-page book, "Nonpareil Corkboard Insulation." Sent free on request.

Canadian Association *of* Stationary Engineers

Incorporated May, 1887
Incorporated at Ottawa June, 1917

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?

If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.

The undersigned will be very pleased to give any further information required.

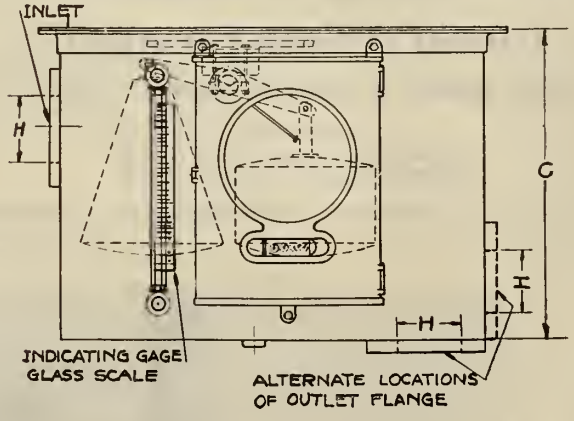
A Bailey Product

The Simplified Way of Measuring Liquids

Illustration shows the operation and general arrangement of the few working parts used in this meter. Note how few adjustments are needed.



BAILEY V-Notch WEIR METERS

For measuring feed water condensate as well as certain other liquids at or near atmospheric pressure, the Bailey V-Notch Weir Meter offers many advantages over the ordinary V-Notch Weir.

The Bailey indicates, records, and integrates the flow of liquids. The pulsating effect of reciprocating pumps does not affect its accuracy. It is extremely simple in construction and is entirely free from troubles arising through the use of cams, springs, racks, gears, and other intricate parts. The Recorder and Integrater are enclosed in a neat iron case and the charts may also show the water temperature.

Write for sizes and complete details.
Bulletin No. 60 tells the story.

It skidded 4000 miles without wearing out

ALL the tires aren't on motor cars. You put tires on your inside packed pump pistons, too. Imagine the difficulty of building a tire that would stand up under a constant sidewise skidding pull for 4000 miles even over the smoothest surface.

Yet this is what Johns-Manville has done by combining a tough asbestos fabric with rubber.

Universal Piston Packing

Universal Piston Packing is folded so that only rounded shoulders can come in contact with the cylinder liners.

This back and forth folded construction provides a wearing surface far superior to the raw edges of laminated packings. It also makes expansion toward cylinder walls possible, taking up wear should it occur—preventing leakage or pump slippage. By vulcanizing Universal Piston Packing in steel molds, the sizes come through with die accuracy.

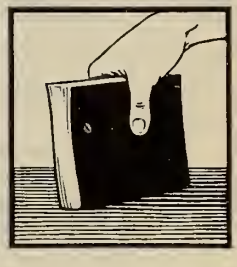
Raising the standards of "Standard Practice"

Universal Piston Packing is only one example of how satisfaction and saving to users accrue from Johns-Manville engineering and research.

As in the case of Universal Piston Packing—you know that laminated packing was "standard stuff" until Johns-Manville raised the standard on "standard practice."

If you aim for plant economies above the general level, ask the nearest Johns-Manville branch to send an engineer to talk the matter over with you.

Rub the trimmed edge of a book back and forth and the cause of the fast wear and splayed leaves of laminated packing quickly shows up—weakest where it should be strongest.



By turning the back binding to the wearing surface, the reason for the folded edge Johns-Manville Universal Piston Packing becomes apparent. Five times the life of ordinary hydraulic packing.

THE REES RoTURBo

A Centrifugal Pump for Any Service

IN the "Rees-RoTURBo" we have the very latest development in centrifugal pump design. The disadvantages of the ordinary pump have been entirely overcome and it meets perfectly the conditions of to-day for high efficiency.

The fluid velocities are low, reducing friction losses to a minimum, and there is no wear even from gritty water, and high permanent efficiency is maintained. This means that the "Rees-RoTURBo" is ideal for multi-stage operation and may be said to be a pump for any service.

Should there be any point on which you would like to be enlightened, our engineering department is always at your service and without any obligation on your part we heartily invite enquiries.

How to Make Use of Logarithm Tables

In This, the Second Article, the Method of Finding Logs and Anti-Logs Is Shown—Proportional Differences and the Treatment of Logs Having Negative Characteristics Are Also Taken Up

IN OUR last article we gave an illustration of the kind of problem that makes it absolutely necessary to use logarithms. We will not attempt at present to show the method of working that particular problem but will give some illustrations of applying logarithms to ordinary multiplication and division sums.

The cut herewith shows a partial table of logarithms, which are taken to six places of decimals. The column at the left marked N contains the number of which the logarithm is to be found. The next column contains the mantissa of the logarithm of that number, the characteristic being omitted. The reason that the characteristic is not put in is because, as explained in our last article, the characteristic depends on the number of integers, or whole numbers in the number. Thus, if the log. of 415 is sought, the characteristic would be 2. If the number is 41.5 then the characteristic would be 1, while if the number was 4.15 the characteristic would be 0. If the number was .415 the characteristic would be minus 1. .415 would be minus 2, .415 would be minus 3 and so on. The mantissa in case would be .618048, as given in the first column of mantissa. The columns following the one containing the mantissa, and headed 0, are followed by columns headed 1, 2, 3, 4. 5, 6, 7, 8, 9, and a final column headed Diff. The way that these are read is as follows. If we want the logarithm of 4151 we first find the number 415 in the left hand column. The first two figures of the mantissa are 61. Looking under the column headed 1 we find four more figures 8153. The logarithm of 4151 is then 3.618153. The logarithm of 4152 would read by taking the first two figures from the column headed 0, and the next four from the column headed 2, and would be 3.618257, and so on, up to 4159.

Now if we have the logarithm and wish to find the anti logarithm or the number corresponding to the logarithm, we proceed in the opposite manner. If for instance we have the logarithm 2.-618571, fe look up in the table till we find a logarithm beginning with 61 in

Partial Table of Logs.

the first column of mantissa. We then look along the other columns until we find the one containing the last four figures of the log. 8571. At the top of this column is the figure 5. The number is then 4155, and as the characteristic is 2 the number will be 415.5.

Now supposing instead of the logarithm or log. as it is usually abbreviated was 2.618469. There is no log. exactly the same as this in the tables. The log. of 4154 is 618466, and the log. of 4155 is 618571. How are we to get the exact number? We must find the proportional difference. and to do so proceed as follows:

The nearest log. below the one we have is 618466, and the number corresponding to this is 4154. Now subtract the log. in the table from the log. whose number we wish to find. Thus 618469 less 618466 gives a difference of .3. Now multiply this difference by 100, which gives 30 and divide it by the number in the difference column,

which is 105. This gives $\frac{30}{105}$ .1857

and this number must be added on the number already found which makes the number 41541857, and if the characteristic was 2 the number will be 415.41857. or 415.4186. The number thus lies between 415.4 and 415.5 and unless the calculation is to be very exact it is usually sufficient to take the nearest log. in the tables and neglect the proportional difference.

In case we wish to find the log. of a number that contains more figures than the tables give, for instance 41569. The characteristic will be 4 and the mantissa will be somewhere between 618676 and 618780. If we wish to get the exact log. we must find the proportional difference. To do this we multiply the figure or figures after the first four, in this case 9, by the number in the difference column. That is we multiply 9 by 105, and divide by 10. Add the quotient to the log. of the first four figures. Thus the log. of 41569 would be 4.618676+9x105945

As we have to divide by 10 this means that we place the 945 under the log. beginning at the second figure from the end thus

```
4.618676
      945
-----------
4.6187705
```

Thus the log. required is 4.6187705

Suppose we wanted the log. of 415698. The characteristic of the log. would be 5 and the mantissa would have to be found by proportional parts. If there is more than one figure over the number to be obtained directly, we must multiply the difference and divide by 100. This is most conveniently done as follows:

Find the log. of 4156 as before which is 618676 as before.

The figures remaining are 98. Then we have log. 415698 =5.618676

```
9x105        945
8x105         840
-----------------
5.61877890
```

As already mentioned, it is but seldom that such a degree of accuracy is required but it shows how simply it can be attained if necessary.

Some Simple Examples

Having made clear just what logarithms are, we are now in a positions to see the actual application in some of the simpler cases. We have stated that in order to perform multiplication of numbers we add their logarithms.

Multiply 4.5 x 4.

```
Log. 4.5 plus log. 4
  .653213
  .602060
-----------
1.255273
```

Then the logarithm of the product is 1.255273. We must look up in the log. table for the anti log. The small part of the logarithm table which we have been able to reproduce here does not contain this log. but it can be found readily by those possessing the full tables. Looking up this logarithm, we find that the anti logarithm is 1800, and as the characteristic is 1, our answer is 18.

Suppose now that we had wanted to divide 4.5 by 4, instead of multiplying we should have had to substract the log. of 4 from the log of 4.5 instead of adding. Thus

```
Log. 4.5 minus log. 4
.653213
.602060
-----------
.051153
```

The anti logarithm of .051153 is 1125, and as the characteristic is nothing the answer is 1.125.

These are simple cases for illustration.

Now let us come to an important application of logarithms, and one where their usefulness will be apparent to all: We mean in the raising of numbers to powers or the extraction of the roots of numbers, in other words evolution and involution, or as many prefer square and cubes and their roots. Instead of the long and abstruse calculations with their immense possibility of error, the use of logarithms substitutes a simple substraction or addition sum, or an even more simple multiplication or division sum. Let us take again the figures 45. We will say first of all that we want to square them, that is 45 x 45.

The log. of 45 is 1.653213, so that we must add the log of 45 to itself to get the log. of 452. This is exactly the same as multiplying the log. of 45 by 2, and as a matter of fact this is what is done. Thus to find the square of 45 we take the log. of 45 which is 1.653213 and multiply it by 2, which gives 3.306426 as the log. of the square of 45. Looking up the tables we find the number is 2025 and as the characteristic is 3.2025 is the square of 45.

Now if we wanted the square root of 45, instead of multiplying its log. by 2 we should divide its log. by 2 Thus the log. of the square root of 45 would

be $\frac{\text{log. } 45}{2}$

```
1.653213
-----------
2
.826606
```

and the anti logarithm of .826606 is between 6708 and 6709. We can find this exactly by the method shown earlier. The next lowest log. to .826606 is .826593 and the difference is 13. The number in the difference column of the log. table is 65, so that we have 1300 divided by 65 which is 20 and the anti-log. of .826606 is 67082, and as the characteristic is 0 the square root log. 45 is 6.7082. It can be readily seen that if we had taken the number corresponding to the next lowest log. it would have made practically no difference in the result in this case.

From these two examples we get the rule. To raise a number to any power, multiply its logarithm by the index of the power. To extract any root of a number, divide its logarithm by the index of the power. To extract any root of a number, divide its logarithm by the index of the power. Here we have a very easily applied method of getting odd powers or roots or fractional powers or roots which it would be extremely difficult to get in any other way. This application of logarithms is worth the study if they are used for no other purpose. We now come to what may be called a special case, although they occur fairly often.

Suppose we have to raise a decimal quantity to a higher power or to find the root of a decimal quantity. Let us take first of all the raising to the 2nd power of a decimal quantity, or getting the square of a decimal quantity, say, .45. Now the log. of .45 is 1.633213 that is the characteristic is a minor quantity. Now how are we to multiply a log. containing a minus characteristic and a positive mantissa. There are several ways of doing this.

Let us take the easiest method first. which is to multiply the mantissa first, and then multiply the characteristic, and then add the two together. Thus we should have .653213 x 2=1.306426, and to this must be added the product of 1 x 2 which is of course 2.

Then we have 1.306426

```
2.
-----------
1.306426
```

The anti-log. of this is 2025 and as we

Synchronous Motors and Power Factor

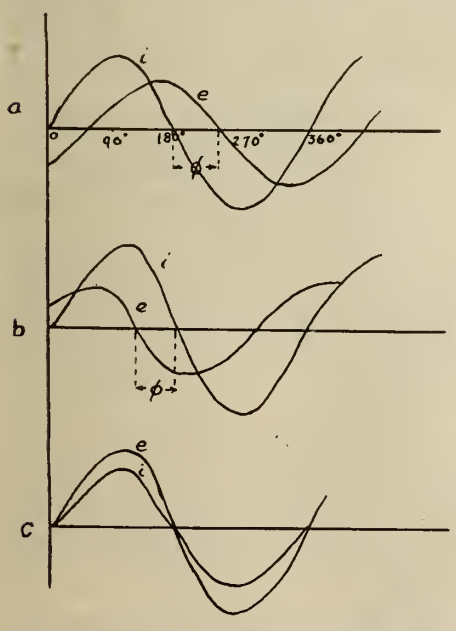
An Article Written in Plain Language, Which Shows the Use of Synchronous Motors in Helping a Higher Power Factor—Power Factor Is Explained for the Ordinary Reader

During the pleasant time of utilizing our natural resources of electric power to the utmost, and considering the high cost of transmission lines, an interesting point in improving the service of electric power and transmission might be discussed; that is the use of synchronous motors or condensers, for power factor correction.

It might be well, before proceeding with the means of correction to briefly disuss the meaning of Power Factor.

It is a well known fact in alternating circuits, that the current and voltage will not usually be in the same phase. That is, as shown in Figure 1, the current and voltage, when plotted throughout a cycle of values will not reach their maximum and minimum values at the same instant of time.

Consider for a moment the plotted curves in Figure 1. These curves are the instantaneous values of current and voltage plotted on intervals of time, and in going from 0 to 60°, they go through a complete cycle of values. In Figure 1a the current is leading the voltage, that is it reaches its maximum, at a definite interval of time before the voltage.



Again in Figure 16, the voltage reaches a maximum value first, and the current is a lagging one. And in 1c the current and voltage are in phase. Again in Figure 1a it is shown that, when the current "i" reaches its zero value the voltage "e" does not reach that corresponding value for an instant of time later and in terms of its cycle, it is Φ degrees behind the current. The fact can be illustrated by means of a victor diagram as in Figure 2. This does not show the complete

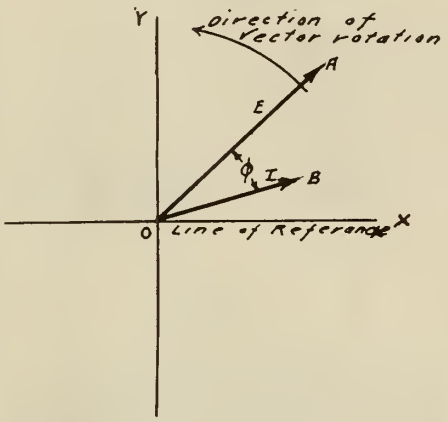


Fig 2.

cycle of values as in Figure 1, but only the value of the current and voltage at the same instant of time. In Figure 2 it shows the voltage victor O.A. leading the current victor O.B. by an angle Φ, and as power is the product of the simultaneous values of current and voltage, the true power must be found, by multiplying the apparent power, by a power factor. This power factor then, has been proved to be, the cosine of the angle of lead or tag, that is, cosine Φ

Thus the relation between power and x current, is cosine Φ.

$$\text{Cosine } \Phi = \frac{P}{E\ I}$$

By way of explanation the cosine of an angle in trigonometry is (for purposes of description, in a right angle triangle) the hypotenuse, divided by the opposite side, that is the side of the triangle made by the angle. Thus when the angle is zero, the side is zero and the cosine of zero is 1, thus the power factor is unity. It is to correct this feature that Synchronous motors are used.

A Synchronous motor may be one of two alternating current generators, operating in parallel on the same bus bars, and the drawing power of one has been removed . It will continue to run at exactly the same speed as before the drawing power is removed. It will be noted that the power is imput, rather than output, as was the case when the alternator was hitched to a drawing power, and it may be termed a synchronous motor.

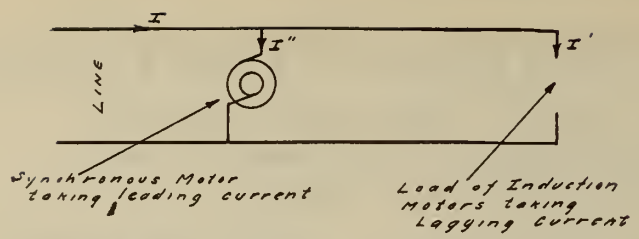
Many manufacturers and users of power are constantly confronted with the problem of too low power factor, (less than unity) and to carry a given K.W. load, at a lower power factor than that originally planned, involves a great many disadvantages. Chief among them are:

1. Large increase of transmission copper cost.
2. Unnecessarily large and expensive generators.
3. Increased cost of distributing transformers and motors.
4. Increased cost for generating station, transforming and switching equipment.

It is pointed out by experts that, in their opinion, the difference in cost necessitated by increasing the carrying capacity of its transmission line, due to its low power factor, might be put to better advantage, by using apparatus to raise the power factor more nearly to unity. Of course it must be considered, as to whether the line will be required to carry a heavier load in the future and also the permanency of the conditions, of the present load, at the distributing end.

The carrying capacity of any electrical circuit, in power, depends on the power factor of the receiving circuit. A certain transmission line, for example, is rated to carry 100 amperes, at 60,000 volts. Hence, when the current and voltage are in phase with one another, the carrying capacity is 6,000 K.W. But the receiving circuit is made up mostly of induction motors and tightly loaded transformers, the current in the transmission line may then lag behind the voltage as much as 45°. Under these conditions the carrying capacity of the line is equal to 60,000 x 100 x cosine 45° = 4240 K.W. Now the earning capacity of the transmission line is only 70.7% of what it is when its carrying capacity is 6,000 K.W. For it must be borne in mind, the fact, the customer pays only for the actual power he uses, that is, E. I. cos. Φ and not the apparent power E. I.

It is therefore advantageous for transmission line owners to contract with customers in such a way as to bring about a high power factor in its line. This can be done if a customer using a synchronous motor is persuaded to run the motor with an over excited field. When such an arrangement is not possible, it generally pays transmission line owners, on long, expensive systems to initial at the end of the line a synchronous motor. In this case it is likely that the motor will not supply any mechanical load, but that it will merely float on the line with the field considerably over excited. In such a case it is called a Synchronous Condenser. Although these machines are designed primarily for power factor correction, they will carry a coupled mechanical load equal to 70% of normal

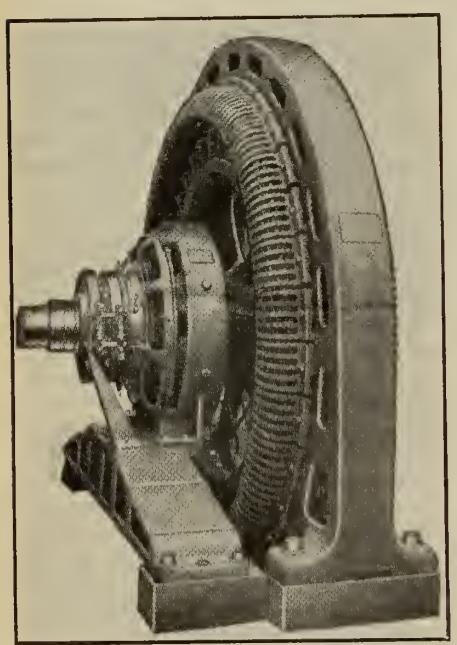


rating in K.V.A., with very little variation in power factor corrective effect.

Figure 3 shown here will illustrate the operation of such a scheme.

In Figure 4 is shown a circuit electrically equivalent to the armature of an over excited synchronous motor, using "C" a condenser and "R" a resistance. It can be proved that this circuit with the proper proportioning of R and C is the exact equivalent of the synchronous motor. Hence, when a motor is used, as in Figure 3 on the line it is called a synchronous condenser.

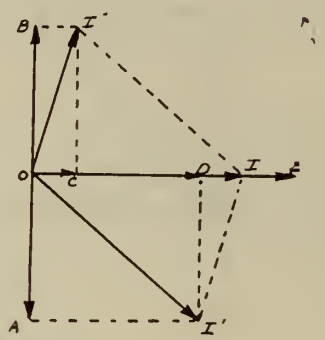
Considering the same situation as



Synchronous Motor With Exciter on Same Shaft.

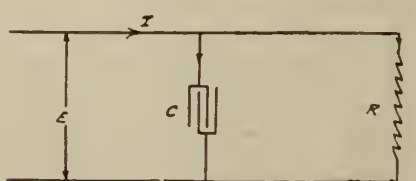
shown in Figure 3, by means of victors as in Figure 5. By this means it can be shown graphically by how much the current may lead or lag behind the voltage. O is the centre and the victors are shown as radii, rotating in a counter clockwise sense about O.

The current supplied to the induction motor is shown as O I (a lagging current) which, it can be proved, can be resolved into two other victors (or components) 90° apart as O.D. and O.A., the resulting effect being the same but it is known that O. D. is in phase with the voltage, and therefore is called an active component of the voltage, whereas O.A. is 90° out of phase with the voltage and is called a reactive component of the voltage. The synchronous condenser current is shown as O.I., which also has two components, O.C. an active component just sufficient to supply its own



losses, and the other O.B. a leading reactive component just equal and opposite to the lagging reactive component of the induction motor O.A. The field of the condenser being overexcited sufficiently to make the above case true. In statistical diagrams of this nature O.I. is the resultant of the parallelogram of which two sides are O.I." and O.I.', or I. is the current in phase with the voltage, which is the victor sum of the leading and lagging currents shown. It is not generally attempted to bring the power factor of the line to unity; this scheme of using synchronous condensers usually results in a power factor from 90—95. That is to say, when the field of a synchronous motor, used for power factor correction is overexcited, there is therefore, a resultant leading reactive or demagnetizing component of its current, which neutralizes the overexcitation, and which is effective in raising the power factor of the connected load, as the line current is the victor sum of the individual currents in the respective apparatus, as shown in the above diagram, and a change in the power factor of one component, brings about a certain resultant variation in the total.

Many companies have found it very satisfactory to install a synchronous mo-



tor in their plants. By way of illustration the generating equipment in one plant consisted of two, 200 KVA, 400 volt, 200 r.p.m., three phase, 60 cycle alternators. A synchronous motor of 250 K.V.A. capacity which corrects power factor and also drives a blower, was installed. Before the installation, the 300 K.W. output of the station was supplied at about 58% power factor. This loaded the generators to the limit of their capacity. Since the installation, the generators are readily carrying a load of 400 K.V.A. which is now at about 95% power factor. This includes a fifty horsepower mechanical load belted to the motor.

The economies effected through the installation of this machine are said to have been such as to pay for it in about a year and a half. When the synchronous motor was first installed, it was possible for a time to carry the entire load with a single engine. It has been necessary to use two generators only since the load has grown.

MONTREAL NO 1 LODGE C. A. S. E.

Montreal No. 1 had an open meeting on Friday, the 25th inst. The chair was taken by Mr. Reynalds, superintendent and director of the St. Lawrence Welding Co. The lecture was on Feedwater heaters and Water Softeners and was fully demonstrated in all its phases by Bro. Henry Wright A. M. E. I. C. Chief Engineer of the Montreal Tramways Co. Power Plant at Hochelaga. Mr. Wright deplored the fact that so few of the manufacturers with steam plants take advantage of the labour saving devices now on the market, and how small was the original outlay, when carried over a number of years, against the cost of mechanical cleaning, year by year. He took the analysis of the St. Lawrence river water and compared it to the water found in many of the Western plants, citing this as a reason why the water softening plants were more numerous there than in Quebec. There were many interesting questions put to the lecturer, and great results were obtained.

HOW TO MAKE USE OF LOGARITHM TABLES

(Continued from page 22)

have a minus characteristic the square of .45 will be .2025.

A second method is to add a positive number to the negative characteristic, and multiply in the ordinary way. After that is performed, the product of the added positive number and the multiplier is substracted from the log. already found.

Using our same figures again for illustrative purposes, we have log. of .45 is $\bar{1}$ .653213. If we add 10 to the negative characteristic we shall have a positive characteristic 9. That is 10 plus 1 is 9. The log. would then be 9.653213 and this multiplied by 2 is 19.306426.

As we have added 10 we must now compensate for that by substracting the product of 10 and 2 which is 20 and the log. will be

19.306426

20.0000000

1.3064260

which is we see the same as before.

In our next article we shall give various examples of logs. applied to the working of actual formula.

What Should The Safety Valve Area Be?

The Writer of This Article Shows What a Great Discrepancy There Is Between the Various Rules in Use and Shows That Practically None of Them Give Sufficient Relieving Capacity

By J. A. McGillivray.

WHAT should be the area of the safety valve? Where is the engineer who has not at one time or other had to answer this question? No doubt he worked it out by some recognized rule or formula. His answer was possibly correct according to the "Rule" adopted by the examining board of his district, state or port, or wherever he was located at the time. But this is where the trouble comes in. There are "Rules" and "Rules," "Formulas" and "Formulas." Why so?

There shouldn't be any disagreement about a good safety valve rule. Yet there are no two that agree with actual tests carried out in this country during the last few years. There are about twenty different safety valve formulas in use on the American continent. Will somebody get up in the Meeting and tell the World what is the meaning of the question anyway, if one man can settle it one way and another a different way and both be right?

Well, some may say those rules "must be right" as there are very few explosions traceable to insufficient safety valve capacity. That so? Do you know why? Isn't it because the safety valve is rarely if ever called upon to do that which it is supposed to do, i. e. to relieve all the steam that can be generated by the boiler when forced to the utmost. When the foreman knows that the load is coming off he checks the fires. There is on one mad enough to force the fires after the safety valves lift. So it may be that in view of the circumstances that the question of a few thousand pounds relieving capacity one way or another does not greatly matter. Well if so, why bother the engineer about it so long as there is a safety valve on the boiler, let it go at that. That is what it amounts to any how and all it will amount to until there is some agreement about rules for boiler construction and boiler safety. But for the present let us consider a given boiler under actual conditions as they came to the writer's notice and we will assume for the sake of argument that some day the safety valve will be called upon to do what it is supposed to do, i.e., relieve all the steam that can be generated by the boiler when forced to the limit under certain conditions of draft, fuel and pressure, etc.

Now I will take for example a boiler upon which I made an evaporation test, some years ago. A boiler which is typical of the modern installation in stationary plants in the United States and Canada and which is insured by a well known insurance company, having two (2) 4½" spring pop safety valves.

The test was run for ten hours, the boiler equipped with a chair grate stoker. During the afternoon we got the furnace temperature pretty high. At one time, during the best hour, the temperature of the furnace was 2470 deg. F.

I have the data for that hour as follows:

Boiler Data.

Com. Rating 600 H. P., Superheat 100 deg. Working press 200.

Water heating surface, 6000 sq. ft.

Grate surface, 110 sq. ft.

$$\left(\frac{H\ S}{G\ S}\right) = 54.54.$$

Test Data

Ave. steam pressure=185 gauge.

Ave. F. W. Temp.=40 deg. F.

Ave. superheat=100 deg. F.

Wt. coal fired=3740 lbs.

Wt. water fed=30,600 lbs.

Factor of evap.=1.3.

Eq. water (F. & A. 212)=39,780 lbs.

H.P. developed=1153=192% comm. rating.

Coal per sq. ft. G.S.=34 lbs.

Water per sq. ft. H.S.=6.63 lbs.

Eq. water evap. per lb. coal=10.63 lbs.

Eff. B.F. & G.=74%.

Heat value of coal used=14229 B.T.U. per lb.

Ave. draft=

$$\frac{42}{100} \text{ inches of water.}$$

The factor of evap. (1.3) is based on Superheated steam at (100°) since the amount of superheating has nothing to do with the safety valve capacity we will have to change the test figures, using the factor for saturated under the test conditions, or feed water at 40° into steam at 195 factor = 1.22.

Then the test becomes

Eq. water evap. from 212 deg. into saturated steam at 212=(30600x1.22)=37332 lbs.

H.P. developed=1080 H.P.

Water per sq. ft. H.S.=6.222.

Eq. evap. per lb. coal=9.98.

Eff. B.F. & G.=68%.

Under everyday operating conditions the feed water temperature is 180 deg. to 200. (Ave. temp. 190 deg.). And when operating at 200 lbs. pressure(the popping point) with an average feed temperature of 190 deg. F. and the same heat transference eff. the amount of water that would be evaporated with such a fire and consequently the weight of steam to be relieved by the safety valve would be equal to the weight of water evaporated into saturated steam on test (30600 lbs.) multiplied by the total heat (H) above the feed temperature per lb. transferred at test, divided by the total heat (H) above the feed (190 deg.) at 200 lbs. pressure.

Under test conditions, total water=30600 lbs.

Under test conditions (H+L)=
[(354.9—8) + (843.2)]
=1190.1 B.T.U. per lb.

Total heat transferred to the water=(1190.1 x 30600) with feed at 190° and steam pressure at 200 gauge, H + L = H =
[(361.4—158) + (837.9)]
=1041.3 B.T.U. per lb. required to evaporate the water into steam.

The total evaporation per hour under working conditions as already stated would be

$$\frac{30600 \times 1190.1}{1041.3} = 38700 \text{ lbs. per hour}$$

to be relieved by the safety valve and this may not have been the limit although I am quite sure it was without an increase of draft. Now these are not supposed conditions but actually existed and might exist again.

Two 4½ spring pop valves having a lift of 1-10 in. would not relieve this weight of steam per hour were they called upon to do so, as we can see by a reference to the table given herewith, as compiled by the Consolidated Safety Valve Company, from actual tests of stationary type spring pops having a lift of 1-10 in.

By reference to the table we find the relieving capacity of a 4½ in. spring pop to be 15,200 lbs. per hour at 200 lbs. gauge. Two of those will relieve 30,400 lbs. per hour or 15% less than the amount that the boiler would generate. Moreover it should be remembered that the average lift is not 1-10 or an inch, the lift of stationary pop safety valves varies from 0.031 to 0.137 with the average at 0.79.

Napiers Formula for the flow of steam air or any gas through an orifice is into some other pressure less than 5-8 of the initial is

$$E = \frac{3600\ A.P.}{70}$$

Where E=wt. discharged per hour.

Where A=the area of the orifice in sq. inches.

Where P=the absolute pressure lbs. per sq. inch.

Size of Valve in inches.	GAUGE PRESSURES (LBS. PER SQ. IN.)												
	60	80	100	120	140	160	180	200	220	240	260	280	300
2"	1890	2400	2900	3400	3900	4410	4910	5420	5920	6430	6930	7430	8940
2½"	2360	3000	3620	4250	4880	5500	6140	6760	7400	8030	8650	9300	9900
3"	3070	3890	4700	5530	6350	7170	8000	8800	9620	10400	11200	12000	12900
3½"	3860	4880	5910	6950	7960	9020	10000	11100	12100	13100	14200	15200	16300
4"	4410	5580	6770	7950	9120	10300	11500	12600	13800	15000	16200	17400	18500
4½"	5310	6730	8150	9570	11000	12400	13800	15200	16700	18100	19500	20900	22400
5	6300	7970	9650	11330	13000	14700	16400	18100	19700	21400	23100	24700	26500

This expression must be multiplied by a co-efficient depending upon the conditions. This co-efficient differs with some authorities. Gebhardts give the co-efficient for safety valves blowing into atmosphere as 0.96, while Babcock & Wilcox use a co-efficient of 0.93 and the Consolidated Valve Company 0.925. The last two being in pretty close agreement and most likely to be substantiated by recent experiments should recommend themselves to general use. Taking the lowest co-efficient since it is better to err on the safe side, where K—co-efficient=0.925, the expression then becomes

$$E = \frac{33600\ A.P.K.}{70} \text{ and } A = \frac{70\ E}{3600\ P.K.}$$

The area of the orifice depends on the lift of the valve and its circumference, that is the circumference remaining the same and the lift is doubled, the area of the orifice is doubled, or the lift being constant and the circumference doubled the area of the aperture is doubled. (NOTE: The area of the orifice varies directly as the dia. and by doubling the dia. the result is the same.)

An example will prove this.

Assume that the relieving capacity of a 4 in. pop valve having a flat seat is to be increased 100%. The lift being 1-10 of an inch.

The area of the orifice=πDL=

$$\frac{3.1416 \times 4 \times 1}{10} = 1.256 \text{ sq. in.}$$

If we double the circumference the area becomes

$$= \frac{3.1416 \times 4 \times 2 \times 1}{10} = \frac{25.12 \times 1}{10} = 2.512$$

sq. inches.

But if we double the disc area of the 4 in. valve we do not double the relieving capacity.

Example:

Area of 4 in. disc = 12.56 sq. in. This multiplied by 2 = 25.12π in. and the corresponding circumference = 17.8 in. and orifice =

$$\frac{17.8 \times 1}{10} = 1.78 \text{ sq. in.}$$

instead of being doubled the area of the orifice is increased only about 42%, so that the only bearing that the disc area has on a safety valve problem is when calculating the load or spring tension required to hold the valve down against the steam pressure.

Practically all spring pop safety valves have 45 deg. seats and the discharge (E) is less than if the seat was flat. When calculating the area of the aperture having a valve with a taper seat the formula becomes

$$A = \pi DL \text{ Cos. } \Theta.$$

Where A = area of the orifice
Where π = 3.1416
Where Z = lift
Where Θ = the angle of the seat.

For a 45 deg. seat Cos Θ = .707. and the formula becomes

$$A = (\pi DL\ .707) = (2.21LD)$$

or combining this with Napier's Formula for a 45° seat.

$$E = \frac{2.21LD\ (360\ A.P.K.)}{7} = \frac{105}{}$$

Then E = (105 L.P.D.)

and $$D = \frac{E}{105\ L.\ P.}$$

Now to show the absurdity of the prevalent idea that the area of the disc is the actual area of the aperture we will take for instance the formula used in the Canadian rules (Interprovincial Regulations adopted by most of the provinces of Canada) Section 272, page 93.

When working pressure exceeds 47 lbs. per sq. in. with coal fuel and natural draft.

$$A = \frac{37.5 \times G}{W\ P + 15}$$

This rule is also in use by the British Board of Trade.

Where A = area of the valve in sq. in. at the point of contact with seat.

Where G = Grate surface in sq. ft.

Where WP = Working pressure lbs. per sq. in. gauge pressure.

Example:

A boiler having 100 sq. ft. of grate. The working pressure being 185 lbs. gauge, find the area of the safety valve, that is required.

Then

$$A = \frac{37.5 \times 100}{200} = \frac{37.5}{2} = 18.75 \text{ sq. in.}$$

If we assume that 18.75 sq. in. is the area of the orifice the relieving capacity would be

$$E = \frac{360\ A.P.K.}{7} =$$

$$\frac{360 \times 18.75 \times 215 \times .925}{7} =$$

1,903,437 lbs. per hour or equal nearly 63,500 boiler H.P. Whereas the actual relieving capacity of such a valve is only about 16,000 lbs. per hour, and the actual area of the aperture or orifice is only 1.08 sq. inches, when the lift is 1-10 in. instead of 18.75 sq. in.

Now we will apply some of the well know rules or formulae to find the size safety valve required for the boiler already discussed and compare the results with the boiler capacity, assuming all to have 1-10 in. lift, the seats having a 45 deg. angle.

Old Rule

$$A = \frac{G}{2} = \frac{110}{2} = 55 \text{ sq. in.} = 8¼ \text{ in.}$$

dia. nearly.

Relieving capacity E = (105 L.D.P.) =

$$\frac{105 \times 8.5 \times 215}{10} = 18{,}906 \text{ lbs. per hr.}$$

Phila. Rule

$$A = \frac{22.5G}{P + 8.62} = \frac{22.5 \times 110}{208.62} =$$

11.86 sq. in. = 3. 7-8 in. dia. say 4 in.
Relieving capacity E = (105 L.D.P. =

$$\frac{105 \times 1 \times 4 \times 215}{10} =$$

9300 lbs. per hour.

Rankin's Rule

$$A = \frac{1{,}406\ W}{P + 8.62}$$

where W = Wt. of coal burned per hr.

$$A = \frac{1.406 \times 3740}{208.62} =$$

25.2 sq. in. = 5¾ in. dia. nearly.
Relieving capacity E = (105 L.D.P.) =

$$\frac{105 \times 1 \times 5.75 \times 215}{10} =$$

13,000 lbs. per hour.

Thurston

$$A = \frac{0.5\ W}{P-10}$$

Where W = Wt. steam generated per hour.

Where P = Gauge pressure.

$$A = \frac{0.5 \times 35{,}000}{210} =$$

83.33 sq. in. = 10 3-8 in. say 10½ in. dia.

Relieving capacity E = (105 L.D.P.) =

$$\frac{105 \times 1 \times 10\frac{1}{2} \times 215}{10} =$$

23,703 lbs. per hour.

B. O. T.

$$D^2 = \frac{\text{Grate area in sq. in.}}{3 \times \text{absolute pressure}} = \frac{110 \times 144}{3 \times 215} = \frac{15840}{645}$$

$D^2 = 24.56$.

$D = \sqrt{24.56} = 4.95$ say 5 in. or its equivalent.

Relieving capacity = (105 L.D.P.) =

$$\frac{105 \times 1 \times 5 \times 215}{10} =$$

11,300 lbs. per hour.

U. S. Supervisors of Steam Vessels

Old Rule

$$A = \frac{HS}{25} = \frac{6000}{25} =$$

240 sq. in. = 17¼ in. or its equivalent.

Relieving capacity = (105 L.D.P.) =

$$\frac{105 \times 1 \times 17.5 \times 215}{10} =$$

39,500 lbs. per hour.

U. S. Supervisors New Rule

$$A = \frac{0.2074\ W}{\text{Abs. pressure}}$$

Where A = sq. in. of safety valve required per sq. ft. G. S.

Where W = Water evap. per sq. ft. G.S. per hr.

$$A = \frac{20.74 \times 352}{215} \times 110 =$$

37.35 sq. in. = 7 in. dia. nearly.

Capacity E = (105 L.P.D.) =

$$\frac{105 \times 7 \times 215 \times 1}{10} =$$

15580 lbs. per hr.

Molesworth

$$A = \frac{4}{5} \text{ grate surface} = \frac{4 \times 110}{5} =$$

88 sq. in. = 10 5-8 in. dia. say 10½ in.

Capacity = E = (105 L.D.P.) =

$$\frac{105 \times 1 \times 215 \times 10.5}{10} =$$

23,750 lbs. per hr.

Thurston

$$A = \frac{4 \times \text{coal per hour}}{P+10} = \frac{4 \times 3740}{210} =$$

Dia. = 9½ in. nearly.

Capacity E = (105 L.P.D.) =

$$\frac{105 \times 1 \times 215 \times 9.5}{10} =$$

21,225 lbs. per hr.

Rankin

A = 0.006 water evap. per hour = (0.006 x 35000) = 210 sq. in. = 16½ in. nearly.

Capacity = (105 L.P.D.) = (105 x 1 x 16½ x 215) = 37248 lbs. per hr.

Thurston

$$A = \frac{2\frac{1}{2} \text{ H. S.}}{P+10} = \frac{2.5 \times 600}{215} =$$

Dia. = 9½ in. nearly.

Capacity = (105 L.P.D.) =

$$\frac{105 \times 1 \times 215 \times 9.5}{10} =$$

21215 lbs. per hour.

Mass. Rule

$$A = \frac{770\ W}{P}$$

Where W = Wt. water evap. per sq. ft. of grate surface per second.

And P = Absolute pressure.

$$A = \frac{770 \times 35000}{215 \times 3500} = 34.81 \text{ sq. in} =$$

6½ in. dia. nearly.

Capacity = E = (105 L.P.D.) =

$$\frac{105 \times 1 \times 215 \times 7}{10} =$$

4673 lbs. per hour.

Darling, for Stationary Pop Valves

$$D = \frac{0.068 \text{ H.S.}}{\text{L.P.}} = \frac{0.068 \times 6000}{0.1 \times 215} =$$

19 in. dia.

Capacity = E = (105 L.P.D.) =

$$\frac{105 \times 1 \times 215 \times 19}{10} =$$

43000 lbs. per hr.

For Marine

$$D = \frac{0.095 \times \text{H.S.}}{\text{L. P.}}$$

Where H. S. = Heating surface in sq. ft.

Where L. = Lift of valve.

Where P. = Absolute pressure.

Canadian Rule

$$A = \frac{37.5 \text{ G.}}{P+15} = \frac{37.5 \times 110}{215} =$$

19.18 sq. in. = 6 in. nearly.

Capacity = E = (105 L.D.P.) =

$$\frac{105 \times 1 \times 6 \times 215}{10} =$$

13575 lbs. per hr.

The ratings or capacity of the safety valves as found by the formula (105 L. P.D.) are less than the actual capacity of the valves under test. This point can be discussed later on.

By application of 13 different rules the safety valve capacities given for a boiler having 6000 sq. ft. H.S. and 110 sq. ft. grate working pressure 200 lbs. gauge having natural draft, burning 34 lbs. coal per sq. ft. of grate, and evaporating 5.83 lbs. of water per sq. ft. H. S. Total evaporation per hour from feed water at 195 deg. into steam at 200 gauge 37,332 lbs. are as follows:

Rule 1 Old English	18,906 lbs per hr.
Rule 2 Philadelphia	9,300 lbs. per hr.
Rule 3 Rankin	13,100 lbs. per hr.
Rule 4 Thurston ..	23,703 lbs. per hr.
Rule 5 Brit. B.O.T.	11,300 lbs. per hr.
Rule 6 U.S. Supervisors (old)	39,500 lbs. per hr.
Do., (new)	15,580 lbs. per hr.
Rule 7 Molesworth.	23,750 lbs. per hr.
Rule 8 Thurston ..	21,225 lbs. per hr.
Rule 9 Rankin ..	37,248 lbs. per hr.
Rule 10 Thurston .	21,225 lbs. per hr.
Rule 11 Mass	14,673 lbs. per hr.
Rule 12 Darling ..	43,000 lbs. per hr.
Rule 13 Canadian .	13,575 lbs. per hr.

Out of 13 rules only three that give sufficient relieving capacity, when the application of the formula A = (105 L. D.P.) gives a valve in excess of 4½ in. dia. the nearest number of valves whose combined circumference are not less than that corresponding to the dia. found will be the size required.

Example:

If A = 201 sq. in. dia = 16 in. circumference = 50.26 four 4 in. valves are required since

$$\frac{50.26}{4} = 12.56 \text{ in.}$$

(But if we divide the area by 4 we have

$$\frac{201}{4} = 50$$

and a corresponding dia. of 8 in.). You see we have four 4 in. valves whose combined area (12.56 x 4) is only ¼ of the area of the 16 inch but having the same relieving capacity.

The foregoing will be interesting to engineers and we would welcome a thorough discussion of the subject. The engineer rarely has anything to do with the selection of the size of safety valve, (that is the operating engineer at least), but he is required to know all about them and to calculate the size, etc. He can figure his safety valve problems in Canada and be 15 per cent. wrong in Massachusetts, or if he figures them out in Massachusetts he will be 67½% wrong in Philadelphia.

There is a difference of 362% between the results found by some of the rules given here and there are yet more rules all equally disappointing.

Alignment Chart for Indicated Horse Power

By A. E. Pennicuick

The illustration Fig. 1 shows a chart drawn up for the purpose of finding quickly any of the values in the formulae

$$I.H.P. = \frac{PLAN}{33000} \quad \text{or} \quad I.H.P. = \frac{P.A.S.}{33000}$$

where P. mean pressure
L. length of stroke in feet
A. area of cylinder
N. number of strokes per min.
I. H. P. indicated horse power.

In order to balance the chart and reduce the number of scales to a minimum the values for L (length of stroke) and N (number of stroke) are converted into piston speed in feet per min. and the value A (area of cylinder) is for convenience converted into diameters.

To read the chart the dotted lines show two examples which will illustrate the method of procedure in finding the required value.

In the upper example a high pressure cylinder of 30 inches diameter has a mean pressure of 110 pounds per square inch and a piston speed of 560 feet per minute. (stroke 4 feet 6 inches and 62 revolutions per minute.) Find the I. H. P.

Join up with a scale or straight edge the point 110 on pressure scale with the point 30 inches on cylinder diameter scale.

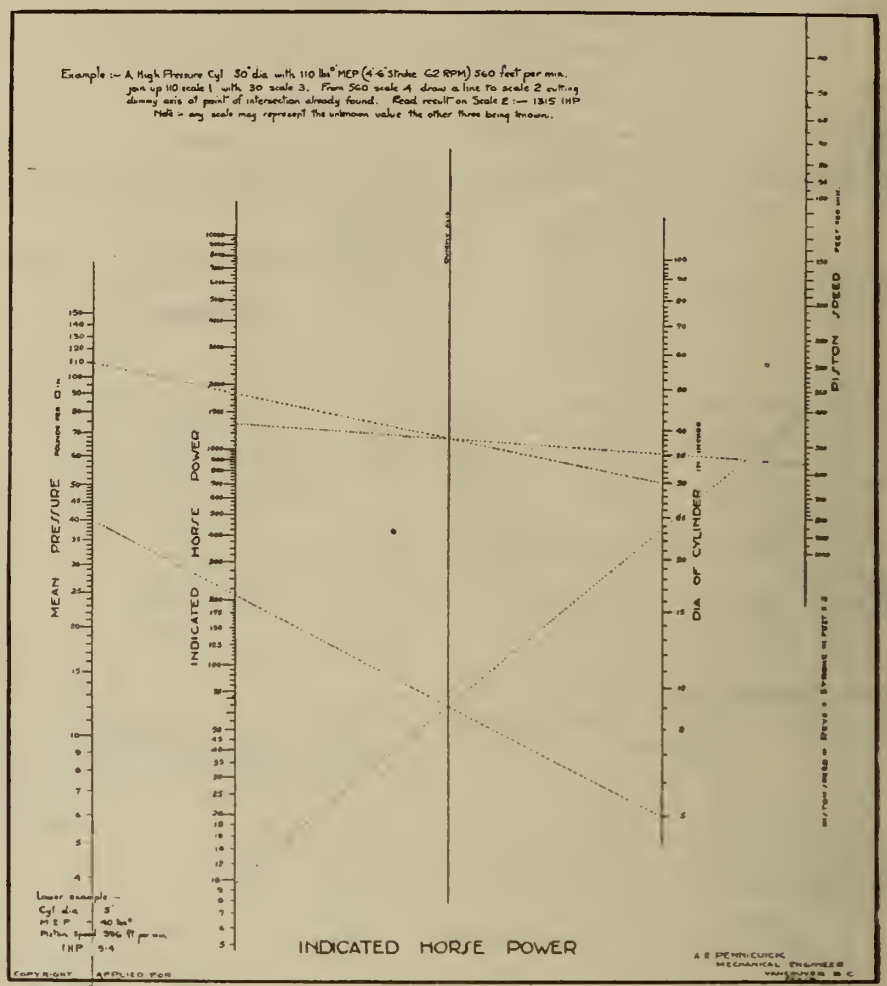
The point on the dummy axis where this line cuts should be indicated with a mark or held with a needle point, and with the straight edge against the needle point swing round until the edge lies on the point 560 feet per min.

The required value may then be read off on the I. P. H. scale 1315 I. P. H.

The lower example has the following values: Cylinder diameter 5; M. E. P. 40; Piston speed 396; I. H. P. 94.

It will be seen that any one of the four values may be the unknown one and that by always cutting the two lines at the same point of intersection on the dummy axis the unknown value can be found.

The notation of the scales should always be the same that is Scale 1 should always join up with Scale 3 and Scale 2 always with Scale 4.



WHEN IT DOES NOT PAY TO RISE TOO FAR

It is irksome not to advance rapidly. It tries one's patience. It makes one sometimes feel discouraged. But the events of the last eighteen months have brought home to many that it is dangerous to rise too far, especially in abnormal times. What has happened in a great many concerns is this: During the boom period promotions were made pretty rapidly. Things moved so quickly and money was being made so easily that promotions and salary increases were not always scrutinized with care.

Then disaster came. Boards of directors ordered drastic retrenchment. In many instances outside experts were called in to recommend reorganization of forces. Their investigations revealed that certain men were drawing big salaries for doing comparatively little work and that these men often were not of calibre warranting the salaries received. When heads began to fall, the heads of such men were the first to drop, In a great many cases, their places were taken by assistants or others who had not basked in the favor of any higher-ups and who were doing a lot of work for relatively little money.

If a list could be compiled of the dismissals during the last year of men drawing salaries of from $10,000 to $50,000 a year, it would create a tremendius sensation.

During this same period not a few able, industrious, conscientious fellows have moved upwards to fill the places of those who rose too rapidly and too far. The law of compensation may often seem to us to operate heartbreakingly slowly, but it does operate. It is safer to be paid less than one is worth than more than one is worth. That's a thought worth keeping in mind.—Forbes Magazine.

Official announcement is made that work on the new hotel at the corner of Richmond and Fullerton streets, London, Ontario, is to begin at once. The hotel will have three hundred rooms and is to cost about $1,500,000.

The City of Guelph is preparing to purchase some equipment for the Civic Water Works plant in connection with the decision to supplement the present steam equipment with that of electrically driven centrifugal pumps. It has been definitely decided to purchase one three million gallon electrically driven centrifugal pump, and one three million gallon electrically driven booster pump, as an auxiliary, two three million gallon gasoline or Diesel driven units will be purchased. It has not yet been decided whether these will be served by gasoline or Diesel engines but it is expected that a decision will be reached shortly.

Alignment Chart for Water and Brake Horse Power

By A. E. Pennicuick

The illustration Fig. 2 shows a Chart drawn up for the purpose of finding quickly the approximate Water Horse Power and Brake Horse Power required or perhaps the head or capacity of a pumping unit.

An example will illustrate the proceddure in finding the required value.

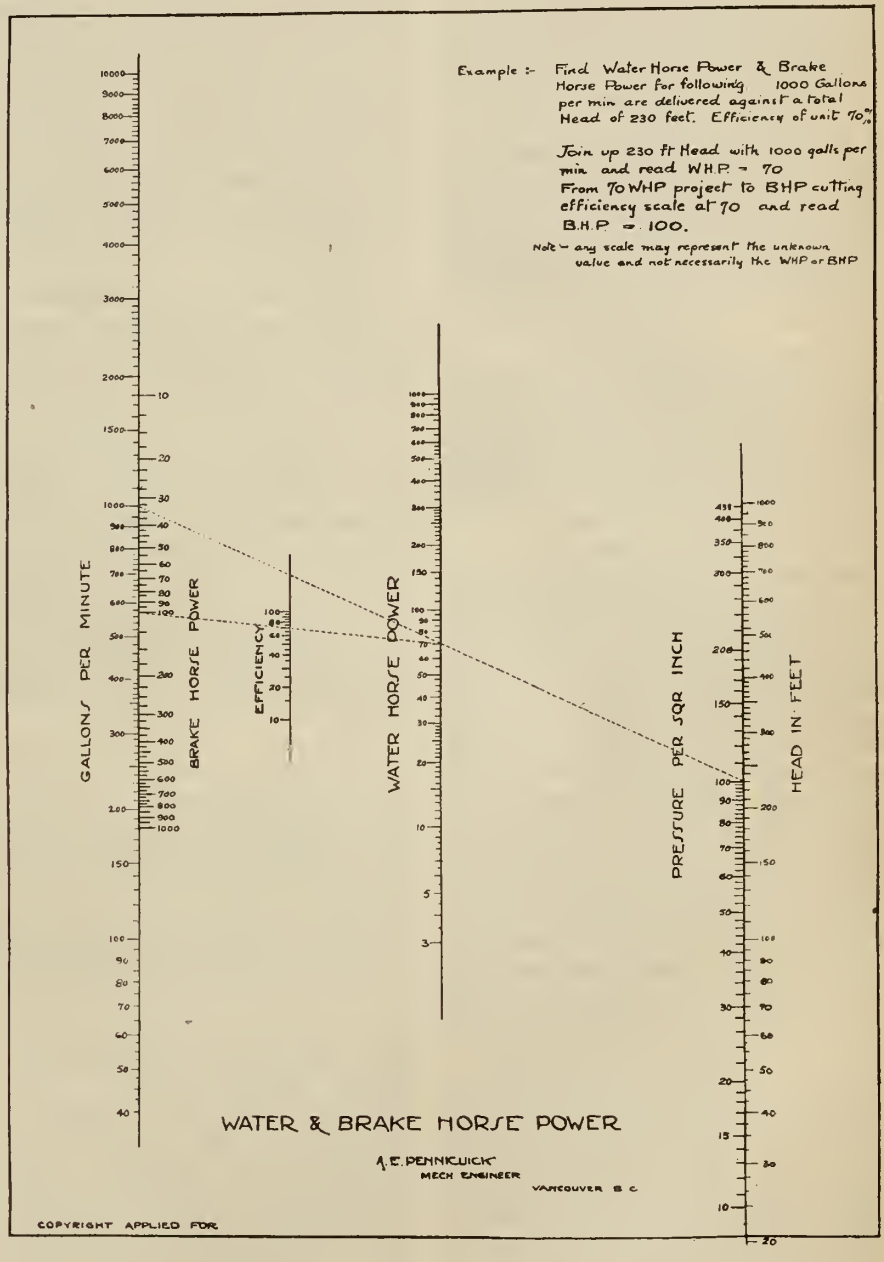
It is required to deliver 1,000 gallons per minute to a total head of 230 feet allowing 70 per cent. efficiency of unit. Find the W. H. P. and the B. H. P. required.

Join up point 1,000 on gallons per min. scale with point 230 feet on head scale and read on W. H. P. scale 70 Water Horse Power.

With straight edge lying on point 70 W. H. P. project across to Brake Horse Power scale cutting the efficiency li- at 70 and read required value 100 B. H. P.

The unknown value may in turn be the gallons per min. or the head and by reversing the above method of procedure these values may be found.

The scale showing pressure per square inch oppposite to the head will be found useful in converting head into pressure values and vice versa.



Example :- Find Water Horse Power & Brake Horse Power for following 1000 Gallons per min are delivered against a total Head of 230 feet. Efficiency of unit 70%
Join up 230 ft Head with 1000 galls per min and read WHP = 70
From 70 WHP project to BHP cutting efficiency scale at 70 and read B.H.P = 100.
Note - any scale may represent the unknown value and not necessarily the WHP or BHP
GALLONS PER MINUTE
BRAKE HORSE POWER
EFFICIENCY
WATER HORSE POWER
PRESSURE PER SQR INCH
HEAD IN FEET

TRACK TORPEDO

The old type of track torpedo which has served its very useful purpose for many years, has been officially superseded by a torpedo of radically new design, on all lines of the Canadian Pacific Railway. This new type is called the "Meteor." A more reliable method of attaching this torpedo to the tracks, than the soft metal bands, is used. It is fastened by means of two spring rail clips made of tempered steel or spring brass, this gripping the rail head firmly, and at the same time being promptly applied. Furthermore, assurance has been made trebly sure. The new torpedo appeals to three senses instead of one, not only hearing, but seeing and smelling. It not only produces a loud report on detonation, but simultaneously a brillant flash and pungent smell.

It is completely waterproof, will stand any atmospheric conditions of heat, moisture and frost. It has been subjected to one hundred hours immersion, and one hour in moist steam at 120 deg. Fahr. without deterioration, and has been used where the temperature was many degrees below zero with complete success. Special tests have been carried out to ascertain its holding power when placed in position on the rail, and for flying particles likely to cause injury to bystanders. These have all been carried out with satisfactory results.

VAPOR ACCUMULATOR

An invention which should be of great interest to every industry with varying steam demands, breweries, sugar refineries, chemical pulp and paper mills, creameries, etc., is the Vapor Accumulator, patented in some thirty different countries, among which Canada and the U. S. A.

The principle of the invention is to equalize the varying requirements for steam in an industrial plant by storing the heat in water when excess steam is being produced, and giving off this steam when it is needed, thus practically making the boiler plant independent of the variations in the steam consumption.

As, under these conditions, the firing can be carried on evenly, and without either forcing or holding back, and as the load, consequently, can be kept comparatively constant, the fuel can be utilized very effectively.

The Brown Corporation, La Tuque, Que., have an installation of a Vapor Accumulator in operation in connection with their sulphate pulp mill, since some six to eight months.

The Vapor Acumulator consists principally of a large tank containing water, in which the excess steam produced in the boiler house during times of light steam demand is stored, while the tank gives off the steam thus stored, when it is needed.

The installation is said to be working very satisfactorily, affecting a considerable saving in fuel.

The Theory of Lubrication*

By William F. Parish

A lubricant has two functions to perform: First, keeping the surfaces apart; second, conveying from such surfaces heat that is caused by friction. Friction comes from two sources: First, abrasion or the metal striking due to the use of too thin an oil, which is called solid friction; and second, the oil working on itself, which is called fluid or internal friction. The art of lubrication is based on the balancing of these factors so as to secure for every possible classification of machinery a lubricant that will keep the surfaces apart at working temperatures and at the same time cause the least internal or fluid friction.

A difference can be noticed in the operation of machinery when lubricated with materials so heavy that they produce internal friction and when lubricated with materials that are properly balanced so that there is no abrasive friction and the oil operates with a minimum of fluid friction.

Loss Due To Resistance Of Oil Films

Loss of power when using a heavy oil is due to the resistance of the oil films. The oil between the surfaces can be considered as a series of films. That which is next to the fixed bearing will drag slowly against the fixed surface of the lining. The drag is related to the adhesive power of the oil; oil that is high in adhesive qualities will drag slower than oil that is not so adhesive. The film that is next to the shaft, at whatever speed it revolves, will be dragging at nearly the surface speed of the shaft, affected also by the power of adhesion—the greater the adhesion the faster it will drag. The layers in between these two films revolve at different speeds; one revolving at comparatively high speed, the other almost still. The effect of this working of the oil films is transferred to heat. The greater the resistance in the oil due to its cohesion or power of clinging together between the surfaces of the various films, naturally the greater the heat developed. This heat is radiated through the bearing and through the air. The conductivity of the metal, therefore, has much to do with the temperature at which the oil is finally maintained.

Every oil requires a certain amount of time)generally from 45 minutes to 1½ hours) to work up to a temperature above that of the room, which is maintained for the rest of the day. The oil, when cold, may be of the proper body to keep the surfaces apart and operate efficiently. However, the heat generated within the oil itself through fluid friction due to constant operation may be sufficient to lower the viscosity or reduce the body of the oil to a point where abrasion takes place. The heat of abrasion will still further increase the temperature of the oil and reduce its effectiveness as an agent for keeping the surfaces apart. It is necessary, therefore, to use oil that will maintain the prescribed body at working temperatures and under the highest surrounding temperatures to which the machinery is subjected. This makes it necessary to use an oil that, when cold, has too much body for effective lubrication, but this oil will generate enough heat in starting to reduce its body so that the balance is obtained.

Oil Requirements of Bearings

Thin bearings that radiate heat quickly require a different oil from bearings designed so that the heat is radiated slowly, allowing the oil to work at higher temperatures. In the latter case, which is generally the rule with the heavier bearings, an oil of considerably greater viscosity must be used originally to compensate for the difference of radiation. The power required to start the shafting when the oil is cold is always excessive, and the power is reduced as the oil heats up. When the heat generated equals the heat radiated, the body of the oil becomes steady and the power required for the operation is likewise steady.

In the case of spindles or light high-speed machinery sensitive to lubrication, the effects of improved lubrication are always denoted by three conditions: First, reduction in power; second, reduction in temperature; third, increase in speed.

The cotton spindle, which for certain classes of work revolves at from 800 to 12 000 r.p.m. is the lightest type of general machinery to lubricate. The oil made for the cotton spindles is the lightest-bodied oil made for lubricating purposes. The basic rules of lubrication which are worked out and studied in connection with the many hundreds of tests on these spinning frames, are applicable to every classification of machinery. Reduction in temperature through change of lubricant is always associated with reduction in resistance to the turning of machinery, even though at all times the speed is not affected. In general, in textile-mill lubrication-engineering practice, reduction in resistance in the spindle bases, with consequent increase of speed of the spindles due to the lessened band slippage and reduction in resistance of all the other machinery, will generally show in an actual increase in speed and production of the entire mill. In extreme cases with overloaded engines the lightening up of the mill through reduction of the frictional loss will result in an increased number of revolutions per minute of the engine and will allow of operating at 10 to 15 per cent less power. Increased production as high as 1½ per cent has been secured with reductions of 10 to 12 per cent in the power necessary to drive the mill.

In straight mechanical-engineering practice, increasing the speed of the mill to secure greater productiveness must always be accompanied by forced increase of power. Forcing machines to operate at higher speed by changing the size of the pulleys or even by putting dressing on belts so that they will have greater traction always places an extra load on the main engine. In lubrication engineering, however, which is a science of reducing friction losses, the savings are all made up of reductions of losses of friction and resistance and of the loss or slippage in belt transmission system.

Illustrating an extreme case of friction losses, a test on a 10,000-hp. reversing rolling-mill engine is cited. It is only necessary to say here that lubrication of this large unit as found was representative of the conditions which existed in steel-mill practice some years ago and, unfortunately, is sometimes found today. Changing the manner and method of lubrication made it possible to reduce the friction load at 88 r.p.m. from 1,239.5 i.hp. to 249.95 i.hp., a reduction of practically 80 per cent.

Analyses of Tests

Analyzing the tests containing these figures showed that the original method of lubricating this unit gave results that approached the laws of solid friction; that is, that while the surfaces apparently were not actually in contact, there was interspersed between them material of such a heavy nature that the resistance was so great as to approach the resistance of solid masses working upon themselves. As soon as the lubrication was changed, the condition approached that which is given by consideration of the laws of fluid friction. It is, of course impossible to secure in a unit of this kind either purely solid friction or perfect fluid friction. This test, however, indicates quite clearly a possible near approach to each of these conditions and represents what takes place in an extreme degree when lubricants are used that are entirely unsuited. In this particular case the great resistance in the engine itself was reflected in the difficulty of handling the reversing levers. The reversing was done by auxiliary steam cylinders as well as by hand levers. It required a full opening of the throttle to the auxiliary cylinder and all the power possible for one man to exert on the hand levers. After the change in lubrication was made, only partial opening of the throttle to the auxiliary cylinders was necessary, and the men would operate the hand levers with ease. Further, it was observed by the operators that the speed of the entire mill was increased. The engine was handled quickly on the reverse and would get up speed in a fraction of the time that was formerly required.

In this case all of the various rules shown in lubrication of spindles applied,

* Excerpts from paper presented at first annual convention of the American Society of Lubrication Engineers.

as far as general lubrication was concerned. The lubrication of the steam cylinders, however, was handled through a new set of factors. The change which was made and the results obtained reducing the load of this part of the unit were due to securing a better distribution of the lubricant through having it properly atomized and carried with the steam where it could be spread upon all the surfaces with which the steam came in contact, where formerly large quantities of a heavy lubricant not suited for the work were forced on the surfaces some seconds after the machine was placed in motion and this oil would be worked back and forth on these surfaces in that form, resulting in much fluid friction. The oil fed in this manner would not spread to the upper part of the cylinders, which were undoubtedly, in consequence, operating metal-to-metal. Of the total 990 hp. saved in this unit when it was turned 88 r.p.m., at least 50 per cent would easily be charged to cylinder and valve lubrication, the remainder to the main bearings, pins, guides and connections.

THE MADE IN GALT EXPOSITION

A very interesting exhibition of made in Galt products, was held in that city from November 12 to 19th. The exhibition was held in the curling and skating rinks, and was largely attended. The exhibits of interest to the power house fraternity were as follows:

Goldie & McCulloch Co.—Rees Roturbo Pumps, showing details of construction; a vertical enclosed, forced lubrication steam engine. A 200 H. P. Wait steam turbine, 3600 revolutions per minute with steam presure of 175 lbs. per sq. inch; photo of engine No. 1 installed 62 years ago and still running in the plant of Chas. Barber & Son, Meaford; boiler heads with gauge equipment, and a display of safety vault doors.

An effective feature of the display was the illumination of a large Rees Roturbo transparency sign by means of violet lights behind a sheet of water falling into a tank from a horizontal pipe about eight feet above the floor. The steady flow of water was supplied by a small Roturbo pump, with a 3 inch intake, attached to a five horse power motor. The pump at 1400 revolutions per minute, had a capacity of 200 gallons with 60 foot head, and demonstrated the ability of Roturbo pumps, even in the smaller sizes, for shop circulation systems, or the general range of purposes. The pump stood on a light wooden frame without vibration or oscillation and apparently motionless although in operation.

Sheldon's Systems:—Keith fans, cupola fans, air purifiers and oil separators, ventilating, heating, exhausting and drying equipment. A model factory building with equipment in position was used in demonstrating a heating and ventilatng. stallation in operation.

The Sturtevant Co. of Canada:—Planing mill exhausters, multivane electric exhaust fans, auto-force ventilators, ventilating sets, gas boosters, electric vacuum cleaners, cupola forge blowers and other ventilating and exhaust equipment.

EMERGENCY OPERATION OF SELF COOLED TRANSFORMERS

On account of self cooled transformers being designed on an ambient temperature of 40 deg. C., advantage of the full rating of the transformer may not be obtained where temperatures are above this point. Such a case happened in a sub-station of the Southern California Edison Company, so that artificial cooling was necessary. To meet the conditions, air ducts were installed around the base of the 5000 kv-a, single phase maximum rated, self cooled radiator type transformer, so arranged with openings placed between the radiators to direct the flow of air supplied by a motor driven blower.

With this method of artificial cooling, these maximum rated transformers will carry 25 per cent. overload continuously with the same winding temperatures as at full load without artificial circulation of air.

The transformers provided with a hot spot temperature indicator, an oil expansion tank and a high voltage tap changer, the latter operated by a hand wheel in a convenient position above the transformer cover.

The plant of Scottish Fertilizers Ltd., one of Welland's new industries, is rapidly nearing completion, and will probably be ready to commence production early in the new year. The plant was designed by British Chemical Engineers and embodies some of the best ideas of British and American practice.

The erection of a central heating plant for the general hospital is being considered by the city of Guelph. Work will be proceeded with as soon as they can raise the sum of $30,000, this being the cost of the equipment they have in mind. Some action will have to be adopted shortly for the present equipment is said to be both insufficient and inefficient.

A fair amount of business is on hand at the Port Arthur Shipbuilding Company Yards, that ensures active operation during the winter months. Extensive repairs will be made to the steamer Huronic, an American vessel that was bought by the Matthews Steamship Co., of Toronto, and which is to be converted into a Canadian vessel. Two large boilers are to be built for the western market. The company plans to construct twenty low-pressure heater. boilers of various sizes during the winter. Hopes are entertained that a contract for the construction of a large bulk freighter for lake service will be placed in the near future.

Mr. Waterhouse, general manager of the Engineering and Machine Works of Canada, St. Catharines, says that his concern are very optimistic regarding business conditions for the coming year.

Georgetown, Ontario, has awarded the contract for the installation of a waterworks pumping plant to Goldie and McCulloch, Galt, the cost to be $9,383.

We are in receipt of an inquiry as to who manufactures "Killametal." This is evidently a compound for the purpose of nullifying the chemical reaction of metals. Any information as regards the name of the manufacturer, or where this product can be secured, will be welcomed by the Editor.

Some figures obtained from the November bulletin of the department of development in connection with the Canadian Pacific Railway show that Canada has risen to second place among the wheat growing countries of the world.

ANNOUNCEMENTS

The Combustion Engineering Corporation announce the opening of two branch offices one in Charlotte, N.C., and one in Seattle, Washington. The Charlotte office is under the direction of Mr. T. E. Nott and the Seattle branch under the management of the Fryer-Barker Co.

The Betson Plastic Fire Brick Company of Rome, New York, announce a change in their selling arrangements in the Central Western States. Frank L. Page of Chicago, Illinois is no longer connected with them in any way whatever, and the Company will again sell Betson Plastic Fire Brick and High Heat Cement direct to the user through its various branch offices and its branch office salesmen.

The Chicago office will be in charge of Mr. C. Z. Dillenbeck, 1514 Kimball Building, Chicago, Illinois. L. S. Shaw & Company, main office 5716 Euclid Avenue, Cleveland, Ohio, with branch offices in Detroit, Michigan and elsewhere will again act as general agents and distributors for the states of Michigan, Ohio, Indiana and Kentucky.

Substantial stocks of their various products will be carried in principal cities to facilitate prompt delivery.

The Betson Plastic Fire Brick Company are the pioneers and originators of the idea of applying an unbaked fire brick in a moist plastic condition, thus making possible and practicable one piece furnace linings, including side walls and arches, also the forming in place boiler baffles at the desired angles to secure tapering passes. No special forms, tools or skill are required in the use of their material.

They issue some very interesting booklets that ought to be in the hands of every owner owning a power plant end every engineer. These booklets will be mailed free upon request.

Didn't Know It Was Loaded

EVERYONE is familiar with, and has smiled in a superior manner at the man who gets shot with a gun that he didn't know was loaded. That there are other things than guns that can contain a deadly charge has been the experience of a man in Ontario during the last few days. His experience has been a terrible one, in that he has lost his right hand, and as the man was an expert mechanic, the meaning of such a loss can be appreciated by all those who work with their hands.

This man was engaged in some repairs on a pump, and during the course of his work, had occasion to remove a nut, perhaps the piston nut itself, or one of the follower bolts. In any case, he had the rod and piston out of the pump, and in order to make the work a little easier, or to make sure of not breaking anything, he took it over to a small blacksmith's forge fire, and put the piston in the fire, holding the rod by the other end. He had only had it there a few seconds, when an explosion occurred, and the piston was torn violently asunder, one piece travelling up the rod in a straight line, and in its course cutting off the hand of the man holding it.

The cause of the accident, of course, was that water had in some manner got into the piston, very probably between the rod and the bore of the piston, or through a porous casting into the piston itself. It's admittance and accumulation would be a slow process, but its raising to boiling point and subsequently to steam was a process of seconds only at the high temperature and comparatively large quantity of heat available in the forge. Once more that terrible force, the force of molecular expansion was called into being, and the frail metal was shattered and with it a man's hand. We have called attention before in these columns to the energy contained in even small quantities of water which have been raised to high temperatures and pressures, and here is another melancholy and painful example to give warning. Never put anything in a fire to heat unless you are morally sure that there can be no water contained in it, and if there is, that there is ample room for the vapor to find its way out as fast as it is formed. Of course, we know that such an accident is not frequent, and it is to be hoped will never become so, but the danger is always there, and no one has a right to take a chance. If he does not know of the danger, he cannot be blamed, but every man who is engaged on work around engines and boiler rooms should know these things, or have them drawn to his attention by the man who does.

Charles Mosley Passes

DEATH has once more visited the Board of Examiners of Stationary Engineers at Spadina Crescent. This time the reaper has gathered in Charles Mosley, the oldest member of the board. The news did not come as a surprise to his many friends, for it has been realised for a long time that Mr. Mosley was in a very delicate state of health. He was sixty-one years of age at the time of his death, and for forty of those years he had resided in Canada. Like his late colleague, Mr. W. C. McGhie, who pre-deceased him but a short time ago, he was widely known and widely respected by all the engineering fraternity in Ontario, and all others whose business brought them into contact with him. He enjoyed the enviable reputation among his fellow men of being absolutely straight and above board, and of having always at heart the interests of his fellow engineers. He was closely connected with the movement for bettering the conditions of engineers in the Province of Ontario, and with the movement for the obtaining of a graded certificate. He was a well known figure at the conventions of the Canadian Association of Stationary Engineers, of which he was a past president. He was also the first worthy chief of the Universal Craftsman's Council of Engineers, when that organization was formed in Canada. He was also a past master of York Lodge, A.F. and A.M., a member of Canada Lodge, I.O.O.F., and a member for thirty years of Warwick Lodge, Sons of England. He was born in Kent, and thus kept up his affiliation with the old land.

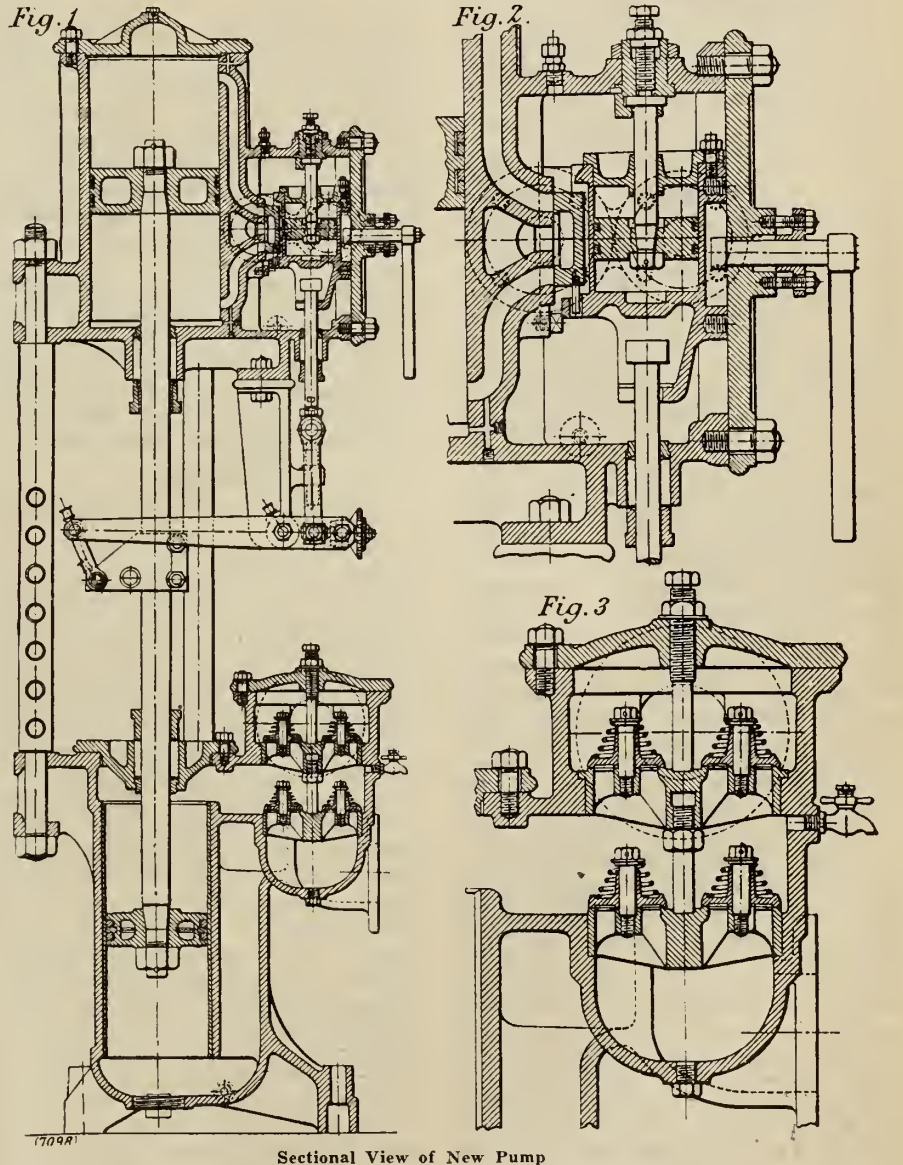
Mr. Mosley had a long and active life as a stationary engineer before joining the Board of Examiners, among the positions held being that of chief engineer for the town of North Toronto, and chief engineer of the Toronto Street Railway plant. His son, who survives him, is also an engineer, being chief engineer of the central heating plant of the University of Toronto. Mr. Mosley is also survived by his wife. His cheerful and kindly presence will be missed from the various circles which knew him, and by his brother engineers in particular.

Progress in New Equipment

DIRECT ACTING BOILER FEED PUMPS

An example of the latest pattern of "Anthony" boiler feed-pump is illustrated in the annexed figures. This type of direct-acting pump, which is built by gineers of Walton-on-the-Naze, P. and Messrs. Robert Warner and Co. (En-O. House, 14-16, Cockspur-street, London, S. W. 1, has proved very successful during recent years, and was supplied extensively for naval services during the war. The steam end of the pump embodies special features which, it is claimed, add to the volumetric efficiency of the unit and enable it to be run at high speeds without danger. Great attention has also been paid to securing convenience of overhaul, and the special steam distribution unit can be removed, examined and replaced in from 3 to 7 minutes depending on the size of the plant. The outstanding feature of the pump is that the main steam valve is moved mechanically for part of its stroke, the motion being completed by steam. This combination arrangement ensures that the piston—and consequently the pump bucket—is brought to rest gradually, and without shock, at each end of the stroke, allowing the pump valves to close firmly on their seats and assisting volumetric efficiency. The valve gear a.so ensures the pump being entirely free from the danger of the piston striking the cylinder covers owing to the pump losing water from any cause and racing. This feature makes the "Anthony" pump very suitable for fire purposes for which it may be necessary to run at a high speed.

The general lay-out of the pump will be clearly followed from Fig. 1. The steam cylinder is carried at the top of mild-steel turned columns, the back column beisg arranged with a series of holes to form fulcrums for a bar when it is desired to move the pump by hand when steam is off. The steam cylinder and valve chest are a single casting, which is of simple form, so that the chest can be lagged as well as the cylinder. The piston rod is of high tensile steel, and is connected at the crosshead to the cold-rolled manganese-bronze pump rod. The pump is of the double-acting type, and the working cylinder is fitted with a renewable gun-metal liner. The water piston is of gun-metal, and is fitted with ebonite, or woodite, packing rings. The valves are of gun-metal of the solid disc type, and are well shown in the enlargement of the valve chest given in Fig. 3.



Sectional View of New Pump

The steam distribution unit which is the special feature of the pump, is shown to an enlarged scale in Fig. 2. As will be seen, the main steam cylinder has a three-ported valve face on which an ordinary slide valve works. Behind this valve, but quite independent from it, there is a small steam cylinder, which is very clearly to be seen in Fig. 3. The piston of this cylinder is fixed, the cylinder itself moving and working on faces on either side of the main valve face. A rod with an enlarged end projects through a gland on the lower side of the valve face. This rod, as shown in Fig. 1, is attached by lever gear to the main piston rod, a fulcrum being provided on a bracket hanging from the main casting. The rise and fall of the main piston rod transmits a reciprocating motion to this rod. To follow out the operation of the gear a condition may be assumed when steam is being admitted to the bottom side of the main piston, and its top side is open to exhaust. Under these circumstances the main piston would, of course, be traveling upwards and the link motion would draw the valve chest rod downwards. As will be seen from Figs. 1 and 2, there is at first a certain amount of lost motion, but when the enlarged end of the rod engages with the bridle at the bottom end of the small cylinder

casting it will pull the cylinder downwards and with it the slide valve, the valve being engaged by a projection on the upper part of the cylinder.

There are two small ports arranged on either side of the slide valve and two corresponding small ports in the small cylinder. These ports are not shown in the figures. At the time when the main piston has nearly completed its stroke, and when the lower main steam port has been closed by the slide valve the small cylinder is pulled down into such a position that small port on one side has passed over edge of main port face, and at the same moment the small port in the other side is put in direct communication with the exhaust port, the result being that live steam is admitted to the lower end of the small cylinder. This cylinder consequently shoots over the remaining part of the travel and carries the main slide valve with it. This action opens the upper main steam port to live steam and puts the lower main port to exhaust. The same sequence of operations is then repeated, the small cylinder being pushed up instead of pulled down. As will be seen from Figs. 1 and 2, auxiliary ports are formed in the main cylinder at the very end of the travel of the piston. Steam is first admitted through these ports when piston commences its travel from either end of the cylinder. The steam connection through these ports also serves to cushion the piston at each end of its travel.

It will be clear that this gear combines advantages of a positive mechanically-driven steam-distributing arrangement allowing of a predetermined and definite cut-off as in a crank-driven pump, and at the same time by employing steam control at the end of the stroke, allows the elasticity necessary in a direct-acting arrangement. The valve gear embodying a controllable cut-off allows of economical working, and losses in the valve cylinder are cut down owing to the fact that it is always completely steam jacketed. We have already referred to the question of convenience of overhaul, and in this connection should point out that the valve unit may be completely removed by taking off the valve chest cover. Both the fixed piston rod of the small cylinder and the moving valve rod fit into forked bridles so that the unit can be drawn out sideways as soon as the cover is removed.—"Engineering."

The Weeks Engineering Corporation, an American organization, has decided to establish a plant at Welland, Ontario. The principal product of the new works will be boiler plates. The company is taking over the Welland Machine and Foundry Company and will install machinery almost immediately. Additional buildings will be erected next spring and the entire site consisting of four acres, provides room for expansion. It is estimated that between seventy-five and one hundred men will be employed in the boiler tube plant.

AN ELECTRIC SOOT RECORDER

Information was published recently regarding an interesting instrument for recording the amount of smoke suspended in the air from hour to hour. In this machine a fixed quantity of air was drawn through a piece of wet filter paper which was stained to a greater or lesser degree by the impurities in the air. Another instrument has been devised in Britain for a similar purpose, and it operates on an electrical principle. It consists of a covered dish containing a small quantity of electrified water over which the air to be tested is passed. By proper adjustment of the rate of flow of the air all the acids in the air are dissolved in the water and the solid particles fall into it. The proportion of acid can be readily estimated by chemical means as the solid impurities make themselves known by changes in the electrical resistance of the water. The advantage of this appliance is that it indicates the amount of acid in the air as well as the amount of smoke. This is an important point as the proportion of acid has a great deal to do with the harmful effect of air upon stone and other structures.

A MUTABLE ELECTRIC SIGN

Dwellers in cities have become quite accustomed to the large electric signs which flash out a variety of messages. They have little idea of the complicated mechanism which is required to provide a series of messages, or the ingenuity involved in their design. The latest type which has been evolved by a British inventor after more than ten years' experiment constitutes a remarkable advance on existing types. Letters, words, sentences, and designs are produced by pneumatic power from movable spheres, each six inches in diameter. By day the spheres twinkle white or in contrasting colors as fancy may dictate, and at night they are automatically illuminated electrically. A sign may be withdrawn and another inserted in its place wthout stopping the machinery; in fact a whole speech could be expressed line by line, and thus delivered more effectively than by megaphone. There is no end to the variety of letters and words which may be made to appear on this sign. The mechanism depends on a simple arrangement of perforated sheets.

A cable from London, England, states that in some things Canada can beat Germany at her own game of cheap production. According to the Mercantile Guardian, after going the rounds of the world's markets, buyers for the first time in many months find Canadian Aluminum the cheapest, selling at 14½ pence per pound, while the German product, despite the deprecation of the mark, is 2 pence dearer. The Canadian product, which is often called American, because it is shipped from New York, is said to be of exceptional quality.

PROMPT SERVICE IN PIPE SHIPMENT

What may be considered as a record in the fabrication and shipment of riveted steel pipe was made in the extension of the Keele Street sewer at Sunnyside, Toronto, by the Dominion Bridge Company recently. The extension consisted of three pipes, each 560 feet long, two of these 90" in diameter and the third one 60" in diameter. The total weight of the contract was 612,000 lbs. The inland ends of three pipes are in the form of thimbles built into a concrete wall. The outer ends pass through the crib work which has been put in place as a retainer for the new "Marginal Way." The pipes are not quite straight throughout their length, they have each two elbows, but the angle of deflection at each of these elbows is less than 3 degrees.

The three thimbles were required in advance so that they could be set in the concrete, but the shipment of the balance—practically the whole of all three pipes—was called for to be made at one time and not later than November 1st, under penalty. The erection to be performed by the Toronto Harbour Commissioners who contemplated the laying of the whole pipe on trestles and sinking it altogether.

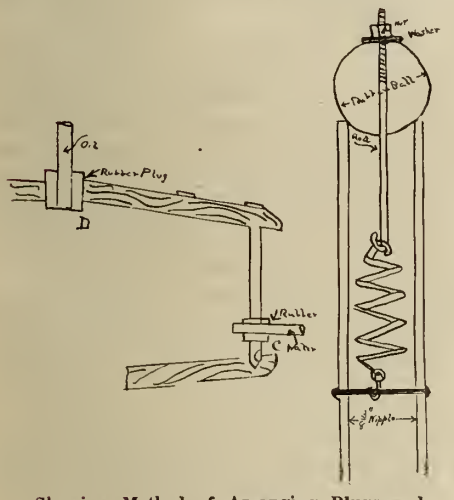
The contract was awarded to the first mentioned company, on September 30th. On account of the character of the work, they decided to fabricate the pipes at their Lachine plant, where their boiler department is equipped for this work. The specification called for boiler quality material. The orders for the material were mailed on October 1st, the day after the awarding of the contract. Prints of the shop drawings were mailed for approval on October 4th, four days after the date of the contract. The material was rolled promptly and was received at the Lachine plant between the 17th and 20th of October. The thimbles were shipped within the stipulated time. The final shipment of pipe was made from Lachine on October 29th and consisted of 29 carloads, each car containing one or two lengths of pipe about 40 feet long. The ends of each section were fitted with flange angles bent to a circle and welded, their outstanding legs being drilled for connecting bolts. This final shipment actually arrived in Toronto at twenty minutes past three on the afternoon of October 30th, two days earlier than the date on which the pipe was called for to be shipped from Lachine.

The Ontario Agricultural College, Guelph, Ont., is to have two new buildings erected to be ready for occupancy in a year and a half. Building operations have already commenced. They will consist of a Dairy and a Veterinary building which will, when completed be the whole to cost in the neighborhood of $150,000. Up to date, motor driven machinery will be installed in the dairy building which will, when competed be one of the finest equipped institutions of its kind in the country. The power plant will consist in the main of two 75 h.p., h.r.t. boilers.

The Operators' Point of View

EMPTYING OIL BARRELS

Several letters have appeared in the correspondence section of Power House in reference to emptying oil barrels with air pressure. Very many engineers, especially in small plants, have no supply of compressed air, where such is the case water can be used. In all cases the water pipe should be several sizes smaller than the oil pipe. A ¼ inch water pipe, and a ¾ or 1 inch oil outlet pipe will be O. K. When this plan is used there is absolutely no danger of a burst barrel when emptying light oils, such as engine or dynamo oil. Heavy machine, lard or cylinder oils should be



Showing Method of Arranging Plugs and Safety Valve

left in a warm location until the oil thins before trying to empty the barrel by either air pressure or water pressure.

Very few oil barrels will leak to any extent under a pressure as high as 5 pounds. At one time I emptied many barrels of oil to an overhead tank, 8 feet high, using compressed air, using rubber plugs at the air inlet and oil outlet and had no burst barrels.

The sketch Fig. 1 shows the water emptying plan. Of course it is necessary to watch the emptying process, otherwise water will be carried to the oil tank when the barrel is emptied of oil.

If the user is nervous, he can easily make a safety valve which he can install in a tee between B. and C. An enlarged sketch of the valve is shown in Fig. 2.

BACK PRESSURE HEATING

Editor,
Power House

In your issue of October 20th you have (in my humble estimation) a good article on "Economy of Working with Back Pressure." We use these contributions in coaching along our night classes, but notice some apparent errors, typographical I guess is the word. For instance in the 2nd column 2nd line it states "1118.7 heat units still available" and in 3rd column near bottom "exhausted at a temperature of 21 degrees."

While you may have it in mind to keep us alive and on the job watching for the sins of compositors and proof-readers you know yourself, Mr. Editor, the layman finds enough puzzling inconsistencies in the measurement of temperature, heat and work to thresh out among the boys, without watching his step for "Latent" pitfalls in the magazines.

A. Ellis
Union Bay, B. C.

We apologise to Mr. Ellis and all other readers for these which are of course typographical, as he surmises. While every effort is made to prevent these errors occurring, a proof reader sometimes slips up, and it is probably too late by the time the editor sees it to make a correction. We are pleased to note that Mr. Ellis can find such an excellent use for Power House, and also that he possesses a sense of humor which is certainly not "latent."—Editor.

Why not a Dominion Wide Certificate

The Editor:

Your editorial in reference to this question is interesting, in that it raises a question many times suggested by new comers to British Columbia. The first thing an engineer is up against when coming from the other side of the Rockies, is an examination.

Permits, or temporary certificates are very seldom granted, and the new arrival usually feels very much aggrieved to think that his certificate is not as good as the one demanded of him.

To sit for the examination, he must first produce testimonials, covering the qualifying time, and these, in many cases, he has lost, or cannot find the firms who employed him. So he rampages around, and expresses his wrath at the inspectors, who by the way, are also the examiners, here, for preventing him from obtaining a job; which brings us to a point you have raised about men outside a certain province having been deliberately refused the opportunity to even sit for the examination. Mr. Editor, it would be fair to mention which Province, as this statement casts a reflection on all the Provinces.

As an Inspector of Boilers for some ten years, I know that no such ridiculous thing ever occured, or was ever hinted at, in British Columbia.

Regarding an earlier statement, "Supposing a local man in town, well known to the examiners, and most of the engineers, and popular with both, is after a certain position; opposed to him is a man from another Province, whose ability to land the job depends only upon his obtaining the local certificate. How much chance has he to obtain this certificate?"

You imply by this, that the examiners would be liable to prevent one man obtaining his certificate, while another, who was better known locally, was allowed to pass his examination.

British Columbia has probably the strictest examinations and examiners in Canada, and there is no inspector that I am aware of, who would be so low as to countenance anything like this. I know of many personal instances where men have been sent to positions within a few days of the examination, by the Inspectors themselves, after having been in British Columbia only a couple of weeks, although it is most unusual for them to know when a plant requires men, as they do not run an employment office in the Boiler Inspectors Dept., here, and do not encourage firms to ring them up for men. There are other means of obtaining men available.

Why suggest generalities that reflect upon a large body of trained neutral and honest men, unless you can lay upon specific instances. I venture to say, that any Inspector in this Province, who did the things you suggested, would soon be advised to resign. A great many of these kind of complaints have no foundation, but a grievance against some examiner who failed to pass a man not up to the standard, or who may not have had testimonials, and was unable to get them, and I might just mention here, that this Government will accept testimonials from any responsible person, who can certify as to the facts that a man operated a certain time; and surely any engineer, who is an engineer, must know some person in some place that can vouch for him.

The fact that a man carries a certificate in his pocket is not necessarily evidence that it is his.

There are a few points about an all Canadian certificate that require consideration. Further along you suggest only two grades. Here local conditions come in. We have four grades here, first, second, third and fourth; and special for logging, traction and creamery, etc.

The fourth class is limited to 75 H. P., but the holder can operate as assistant on a third class plant, and so on. A third can operate 375 Boiler H. P., and act as assistant to a second class, who upon non-condensing, can operate unlimited, and upon condensing, 750 H. P. The first is altogether unlimited. We had a fifth class at one time for loggers. This has been abandoned, and now there is a loggers special. Why? There is good reason for these things. A man who passed his examination in Ontario for operating with a second class certificate, and who had obtained his experience in a stationary boiler plant, would not only be a failure on a logging donkey for a long time, but a very serious menace to the men working with him. You may have seen photographs of the logging industry, and will readily conceive that it requires special knowledge. So a man cannot obtain this certificate unless he has had at least six months experience in a steam operated logging camp, and obtains a reference from his boss, that he considers him qualified. Then the Government will examine him as to his capabilities as an engineer.

Is there any Dominion wide examination which can ever cover this point? A man from Alberta, for instance, could never get this certificate until he had been in British Columbia at least six months. Can you compare logging in Ontario with logging in British Columbia? I do not know, but from what I have heard, I think not.

Why the lower grades? Such as third and fourth, simply because it would be impossible for many men to pass the higher grades. Would it not be a sort of discrimination—I think it would—to shut these men out of a livelihood, because of their inability to absorb a certain amount of necessary knowledge, and because they had not sufficient practical training?

The two class certificate means, in this Province, a lowering of the standard of Engineers examinations, and unless you concede this is necessary, and advisable, I do not see how you can bring it about. Even so, no process of elimination would do away with the special certificate mentioned, and others of the same calibre, where special knowldge is regarded as necessary; not so much from a safety point of harm to the boiler and engine or plant in general, but to the safety of the men working around the plant.

Turn the average first or second class stationary engineer loose on a steam shovel, and where does he get to. He may succeed in hurting someone or upsetting a car, or possibly his machine; at anyrate, his chances of success are poor without a reasonable amount of training of some kind previously.

In British Columbia, no fireman has to have a certficate unless he is the engineer as well. But no man can be alone in charge of a boiler plant unless he has a certificate applicable to that plant.

These conditions might well be reversed, and the British Columbia man go East, and he would be in exactly the same condition as his compatriot from the east. Both as regards to his ability for specific lines, and for his ability to get the work done quickly, safely and well.

The question of an examining board, you have brought up, and of the Dominion Government appointing Inspectors to watch the examiners. These Inspectors would most naturally be appointed, say one from each Province, and would more than likely reside in that particular Province, and so would only be an additional source of expense to the ratepayers at large.

Would a Dominion wide certificate make any difference to a man's chance of being examined without prejudice? If we grant, for instance, your assertion that discrimination might be shown a man because he had not been in a Province long enough to compete with an old timer. What difference would that make if he had to go up for examination, whether it is an all Canadian certificate or local. He would be in the same position as if he had to obtain the local certificate, anyway. He might have an even chance if he had already obtained the certificate in some other province, but not necessarily so.

This question you have opened up, Mr. Editor, is far too long to write about in one letter. The subject is far too broad and consequently will suggest it time enough for me to give some further views after others have expressed theirs.

In conclusion might I suggest that the experiences of the different Provinces with local conditions peculiar to themselves, is one factor which would be difficult to overcome with an all Canadian Certificate.

Yours very truly,
Percy A. Goepel.
Vancouver, B. C.

EDITOR POWER HOUSE

Having read the article in Nov. 5th issue of Power House re Dominion wide certificates for stationary engineers and I think it a fine idea and one that should be given very deep consideration as I can not see any reason why a man that is capable of handling a steam plant in one province should be barred from operating a plant of similar size in any other province of the Dominion. One cannot wonder much at a province that has a good standard of examinations for engineers not wanting men from Ontario as the last year or so has been such a huge joke that any person that had the price could get a certificate but since the coming of the graded certificates the standard of engineering in Ontario has been raised and is fast coming to the point where it rightly belongs and I hope that time will come when engineering in Ontario will be on a par with other provinces.

I just want to ask a question regarding the amendments to the Engineers' Act. Does it mean that a man who is in charge of a plant of over 600 B. H. P. must hold a first class certificate or does it mean any person wishing to take charge of a plant of over 600 B. H.P. must obtain a first class certificate?

Hoping I am not to bothersome, I am, yours truly,

Frank Moore,
Sarnia

The letter under this heading in the November 5th issue of Power House has brought forth so far two replies, one in agreement, and one which does not agree. These letters are both published in this issue, and some of the points brought up by Mr. Goepel will be answered here.

First of all, Mr. Goepel requests that the name of the Province wherein men were refused examination should be stated, as otherwise it is unfair to other provinces. That may be so, and perhaps it would have been as well not to mention that particular case, but we would inform Mr. Goepel that the inspector in question has been retired for some years now, and it would serve no good purpose to mention any names in connection with the case. We would be willing to furnish Mr. Goepel with the particulars for his private information if he should wish it.

As to inspectors, or examiners, being inclined to give the benefit of the doubt to a man who was perhaps very well acquainted or even friendly to them against a stranger, well, after all examiners are human, and it is by no means impossible that even a very fair minded man might be influenced a little by his feelings in a case like that.

That the fact of a man having a certificate is no proof that the certificate is his we must admit is true and we have used this argument to an examiner who suggested that all men holding a certain certificate were inferior to the local men, because he had a man come before him who held this certificate, and could not pass his examination. However, in the case of a man coming from another province or country, he usually has documentary evidence to prove his assertions, and if not should certainly be required to prove his status. In the case of a man holding a Dominion Certificate, it would be a simple matter to verify his claims. The British Board of Trade certificate has to be signed by the holder when he receives it and it is a simple matter to compare the signatures of the applicant for a position with the signature of the certificate. A photograph could be used as in the case of a

passport. The question of identification could be easily got over.

Now when it comes to a question of the lower grades of certificates and the issuing of special certificates for logging, hoisting, etc., we are at two different points. Mr. Goepel seems to think that if the certificates were limited to two grades, that the standard of qualification would be lowered or that a large number of deserving men would be prevented from earning a living. Neither of these undesirable conditions need accrue from the abolition of the third and fourth grade certificate. We have also in Ontario a fourth and third grade certificate, and as far as the fourth grade is concerned no one would be hurt by its abolition. This certificate must be held by any man who desires to operate a steam plant of between 25 and 50 h.p. or to operate under a certificated engineer a plant of 50 h.p. or over. In order to qualify for this certificate he must be 19 years of age, and have six months experience of operating, including at least three months operating in the boiler room. That means as far as its actual reading goes, that a man holding this certificate, can operate under a certificated engineer any size plant where he can get a job. Now independent of the certificate how much chance would he have of getting on a shift in a big plant, to take charge? He would have to have considerable more experience than the six months necessary or else be a very brilliant man. On the other hand there are hundreds of men who couldn't pass any kind of an examination, but who could take a watch in the engine or boiler room of almost any plant, and be perfectly safe. How many ships are there at sea today with the donkeyman taking charge of a watch, day after day and night after night, and carrying on in perfect safety. The qualifications of this candidate for the fourth class certificate, which he must have acquired after six months experience, include a general knowledge of all types of boilers, and a thorough knowledge of the construction, care and upkeep of injectors, a general knowledge of the different types of pumps, both centrifugal and reciprocating. This is not all, but it can be seen that the examiner must take a very liberal view of the interpretation of these qualifications—if any candidate passes the examination after six months experience. The qualifications for third class are such that if they were strictly adhered to, there would be no third class men passing until they had spent a very considerable time at the business, or else had a technical school or University education. This being so, would anybody be injured if a man was compelled to serve three years in the boiler room and engine room under certificated engineers, before he was allowed to sit for a certificate at all, and then give him a second class certificate if he could pass an examination of the required stiffness? In three years if he availed himself of his opportunities he could get a pretty fair knowledge of the practical end of his business, and then with study he could attain the theoretical end. After obtaining his certificate he could either take charge of a small plant or get assistant on a large plant and work his way up. It must be remembered that the average employer is governed far more by the types of plants the man has had experience in, and his record as ascertained from previous employers, than he is by the certificate he holds, so long as the latter will come within the law. We believe that such a method, with all the certificates of one standard, would not deprive any man of a job, and would tend to elevate the standard of engineers instead of lowering.

When it comes to a question of logging or hoisting engineers, we have a different proposition altogether. So long as a man knows enough to keep his boiler supplied with water, and to start and stop his engine, and keep it packed, the engineering side of his job is completed. When the question of becoming an expert operator of a hoist or a logging donkey is considered, how is he to attain that proficiency? In only one way, and that is by getting a start, and practising until he becomes expert. All the certificates in the world will not help him to do that. When a man is looking for a job of that kind, the logging boss will not ask him what university he graduated from, but will ask him to step on the platform, and demonstrate what he can do under the watchful eye of the boss, who will make sure that no one is liable to be killed until he is satisfied of the man's ability. These men are hardly to be included in the list of stationary engineers at all. The longshoreman who comes aboard a ship to run the winches while the cargo is unloaded, does not know a crank shaft from a piston, but he is a mighty expert winch handler. Where does he learn it? Usually, he is called on to try his hand for the first time when a regular man is short, and under the eye of the stevedore, he proceeds cautiously until he begins to get confidence in the job. Then he improves from day to day, until it becomes recognised that he is a capable man to put at a winch, and the news gets around among other bosses that another man is available in the field of winch handlers. Would a certificate help him any? Hardly.

We shall be glad to hear from Mr. Goepel again, and any other engineer who has ideas on this subject, as we believe the present state of engineers' certificates could be much improved taking Canada as a whole. We do not wish to push our views as the only correct ones, but to get the opinion of the men who should be the most interested.

In all probability the sum of $100,000 voted by the legislature at the last session for providing additional parliament building office accommodation will be utilized in the construction of the new building on the site of 17 Queens Park, Toronto. Honorable F. C. Biggs, Minister of Public Works, is having tentative plans drawn up for a new departmental block on the east side of the crescent.

A CHALLENGE ACCEPTED

The Editor, Power House:

I see in your issue of November 21st under the heading of "A Challenge," calling attention to an article I wrote some months ago on a tube fracture which occurred in the Montreal Tramways Co., Power House at Hochelaga.

I am very sorry if I seemed discourteous to our friend Mr. McLaren at the time in not answering his idea of the cause of the accident and results. If he will somewhat revive his memory he will remember I asked an opinion on the failure of a Rado-jet two issues before that and got no response from anyone. When one answer only was sent in to the second question I am afraid I was very disheartened, and I think a little disgusted at the lack of interest taken in subjects brought to the notice of Engineers in the Power House Magazine. Mr. Fenner and myself had a very lengthy and interesting discussion on both subjects during one of my visits to Toronto, which terminated to both our mutual satisfaction and the subject passed from my mind.

Our friend speaks in lighter vein of the accident. Probably if he had been in the mix up, as he calls it, he would have required a little more than 2½ per cent to steady his nerves.

I may tell him that the matter was thrashed out by some of the best brains in the States and Canada, and if our friend would like a copy of the reports sent back by experts I am only too willing to mail him one, but he must understand it is strictly confidential, as my company would not allow me to publish it. Otherwise I should only have been too pleased at the time, to let Power House publish it. However if our friend is anxious to air his knowledge before the engineering world, and will give the same explanation, I will tell him through the pages of Power House, how far he is from the truth. I am sorry I have not a copy of that date, as I send my copies away, and this particular one I sent to England, to be discussed, which was done. I am rather surprised at our friend in the previous article, on the same page, questioning such an authority as Mr. Pratt. He certainly is brave to throw himself in the limelight of the engineering world and dare to make such an assertion.

Before concluding, I would like to impress on Mr. McLaren's mind, that an engineer in charge of a 40,000 H. P. Plant has more on his mind than tube fractures and again if I seem discourteous, forgive me and enter into a good controversy without that touch of cavil, which ill becomes a man towards his brother engineer. As a concluding remark, my reputation as an engineer is in no jeopardy, from such discussions as our friend wishes to bring up.

Hoping, Mr. Editor, that this will fully answer the article in question.

Henry Wright, A. M. E. I. C.
Chief Engineer.

JAMES E. NOBLE REPLIES

In November 21st Power House, under the title "A Challenge" there is a letter in reference to a letter of mine printed in October Power House. Because I did not write a guessing reply to a letter of inquiry, sent in by Henry Wright of Montreal, some 18 months ago, (which letter I did not see) your correspondent proceeds to write nasty sounding words such as, "your correspondent so far has not risked his reputation by expressing an opinion."

It is just such egotistical writers and their ill-natured quotations that are responsible for some inexperienced writers refusing to put their pen to paper for publication.

Your correspondent practically admits he did not know the answer as to the cause of the trouble, but did this check him? Not so you could notice. He gave it long distance, absent treatment by guessing. Most engineers refuse to guess for publication, if they know, then it is different. Henry Wright of Montreal has had a long practical experience in very large plants. When such a man asks a question surely the man of, possibly, lesser experience should not be taken to task, even by suggestion, by a guesser, because he did not answer a letter he never read. In my letter I suggested that engineers, meaning young or old, experienced or otherwise, without distinction or prejudice would assist a lot of us who might encounter some unusual difficulty, if they would describe how they overcame some such affair. In thousands of cases experienced men in different lines of work have been helped over a hard point by some suggestion thrown out by an inexperienced helper. No one man knows very much when everything pertaining to engineering is taken into consideration. Your correspondent might just as well suggest that our Editor, who is also Engineering Instructor at Toronto Technical College, an expert in Marine, as well as stationary engineering practice, is afraid to risk his reputaton because he did not answer the letter in question.

It is much more satisfactory to have some engineer explain how he won out, than to have him offer some uncertain advice. However, the latter is often welcome and once in so often may hit the mark.

The foregoing is an answer to "A Challenge." In two different sentences he writes he will be listening, surely he understands this is wrong, he can see, not hear in print.

Because one man has written a letter of inquiry to which only one guessing reply has been sent, it shouldn't deter other engineers from sending in what they consider valuable information to Power House, it may be some other engineer will be thereby helped, even if this does not happen, no harm will be done. By all means put us wise how you won out in that bad time.—James E. Noble.

Editor's Note

We would request, that in this correspondence, between three good men, that personal recriminations be kept strictly in the background. We have the pleasure of knowing both Mr. Wright and Mr. McLaren personally, and have accepted a considerable number of valuable contributions from Mr. Noble, although it has not been my good fortune to meet him. All three have a long experience, and a pretty wide knowledge of engineering as applied to power plants, and between them can furnish much valuable information to brother engineers when they feel like contributing to "Power House." There is no objection to them having an argument on any point at all, but we would ask that in the interests of decorum, and for the good of the profession in general, that this argument be carried on in a parliamentary manner. The letters here published are not by any means in a conciliatory strain, and we remember a correspondence some time ago that descended to the level of more personal abuse. Gentlemen, keep clear of this style of letter writing, or the correspondence will die a sudden death.

HORSE POWER AND BOILER RATING

Editor, Power House:

In 1876 a committee of judges in charge of the boiler trials at the Centennial Exposition in Philadelphia recommended that a boiler horse power be the equivalent of the evaporation of 30 lbs. of water at 100° Fah. into steam at 70 lbs. gage pressure. This is equal to 33354 B. T. U. according to the Marks Davis tables.

In order to further simplify matters the American Society of Mechanical Engineers have recommended that a boiler horse power be the equivalent of the evaporation of 34.5 lbs of water at 212° Fah. into steam at the same temperature. This is equal to 33479 B. T. U.

In order to facilitate the calculation of electrical drives, etc., the late H. G. Stott suggested the myria watt be considered the equivalent of one horse power. A myria watt=10 kilowatts and the thermal equivalent of one K. W.=3412 B. T. U. A myria watt therefore would equal 3412 x 10=34120 B. T. U.

Boiler builders in rating their boilers allow 10 square ft. of heating surface per horse power in the case of water tube boilers and 12 sq. ft. in the case of return tubulars. The Boiler Inspection department of Ontario also allows 12 sq. ft. of heating surface per horse power for return tubular boilers.

The formers of the Stationary Engineers' Act, however, for some unknown reason decreed that 15 sq. ft. of heating surface in the case of a return tubular equal one horse power. Possibly it was the best they could get out of their boilers or possibly they thought the other fellows were wrong, but my suspicion is that most of us get a horse power out of less than 15 sq. ft.

I am satisfied that the present members of the Stationary Engineers' Board are aware of the fallacy of the rule and would appreciate an expresion of opinion on the subject by engineers. What is your opinion?—R. M. McLaren, 160 Dovercourt Road, Toronto.

OBITUARY

The death of Lord Mount Stephen occurred at his residence in Hertfordshire, Brockett Hall, Hatfield, England, on November 30th. Lord Mount Stephen was in his 93rd. year. He was born in Scotland in the rural community of Aberdeenshire, June 5th, 1829. He spent his early days there and in Banffshire. He never forgot his school days in Dufftown. He was born a commoner and was known as plain George Stephen. He started life as a shepherd boy, later going into a draper's establishment in Aberdeen. He soon entered the services of a shipping office in London. An opportunity of coming to Canada presented itself shortly after, and he came to Montreal in 1850. He entered business as a woollen merchant, in 1862 was in control of the business. He also achieved great success and amassed a great fortune in the textile manufacturing business. He became a director of the Bank of Montreal and in 1876 became president of that institution. Through his connection with the bank he became interested in railways. With his Scottish cousin, Sir Donald A. Smith, (later Lord Strathcona) he accepted the responsibility of building the Canadian Pacific Railway across the continent. The Canadian Government had only built 700 miles of the road and the enterprise was apparently doomed to failure. This railway syndicate, as it was then known, received $25,000,000,00 in cash and 25,000,000 acres of land as a subsidy. Difficulties of all kinds, some almost insurmountable, confronted the railway builders time and time again. Lord Mount Stephen's brilliant personality, his faith in the future of Canada, and his courage, were outstanding in the days of political and financial difficulties. In order to complete the road, the personal fortunes of both Lord Mount Stephen and Lord Strathcona were pledged. Many of his securities had to be sacrificed to raise funds. Lord Mount Stephen became the firt President of the Canadian Pacific Railway. He was plain Mr. Stephen when he was elected to this office in 1881. He held office until 1888 when he resigned.

His gifts to hospitals and other worthy objects were princely, and he distributed his vast fortune in a lavish style. For the past twenty-five years he has lived quietly in retirement in England but always took a keen interest in Canadian affairs.

If Guelph can raise $320,000 they will erect a new high and technical school. Day and evening classes will be held in such a school, but so far the matter is only in a proposed state.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

SIZE OF PUMP

Question:—Can you please tell me the size of feed pipe necessary for a 170 H.P. water tube boiler, carrying 100 lbs. pressure, and how to figure same. Also what size of duplex feed pump would be most suitable for it?

Answer:—It is first necessary to determine how much water must be supplied to the boiler for the given horse power, and if the boiler is to be run at over rating, allowance must be made for this. As one boiler horse power is the evaporation of 34½ lbs. water per hour, and the horse power is 170, then the quantity of water to be pumped would be 170 x 34.5 lbs. per hour. If we allow for a 50 per cent. over load it would be

$$\frac{170 \times 34\frac{1}{2} \times 150}{100} = 8797.5 \text{ lbs per hour}$$

As there are 62.5 lbs. in a cubic foot of water the number of cubic feet per hour would be

$$\frac{8797.5}{62.5} = 140.7$$

or say 141 cubic feet per hour. This gives 2.35 cubic feet per minute. Now it is necessary to limit the velocity of the water through the pipes to about 150 feet per minute, as if the velocity exceeds 200 feet per minute there is a great deal of loss by friction. The cubic feet per minute passing through the pump is 2.35, and this in cubic inches is 2.35 x 1728=4060.8 cubic inches. The velocity is to be 150 feet per minute and this is 1800 inches. If we divide the cubic inches per minute by the velocity we get the area of the pipe, and this divided by .7854 and the square root taken gives the diameter of the pipe. Put in mathematical form this will be

$$\sqrt{\frac{4060.8}{1800 \times .7854}} = \text{Diameter}$$

and diameter of pipe is 1.69 inches. Now this is over 1½, and the best thing to do is to take the next largest size, 2 inches, which will make the velocity less than 150 feet per minute, and provide ample capacity for the feed.

To determine the size of pump required we refer again to the cubic feet per minute required which is 2.35. As a duplex pump may be considered to be 80 per cent. efficient that is a slip of 20 per cent. is allowed, we must have a pump that will deliver that quantity of water net. We shall require then a pump having a capacity of 2.35 x 1.2= 2.82 cubic feet per minute. As there are two pistons, each one will have to deliver 1.41 cubic feet per minute. It is not desirable to have a feed pump moving too quickly, and a speed of piston of about 50 feet per minute is plenty. This is 600 lineal speed per minute. 1.41 cubic feet per minute, we should have an area of 4.06 square inches. This would give a diameter of a little over 2 and one quarter inches for the piston. In order to get the speed we should have to make at 60 strokes per minute with stroke of 10 ins. This is not at all in proportion, so we can tackle the question another way. We can use a slower speed and a larger bore which will be more satisfactory. If we determine the number of strokes we wish the pump to run, then we can make a bore and stroke to suit this speed. Let us take 30 as the number of strokes per minute, then the quantity of water per stroke will be 81.2 cubic inches. Let us assume a diameter of 4 inches which gives an area of 12.5 square inches. This divided into 81.2 cubic inches gives a stroke of 6.48 or say 6½ inches. We can make the stroke 6 inches and let the pump run a little faster, and then we should have a pump with water ends of 4 inches diameter and 6 inches stroke.

For the steam cylinder we should make the ratio of these areas about two to one. If the water end is 4 inches then the square of 4 is 16, and twice this is 32. The square of 6 is 36 so 6 inches would be about right for the steam cylinder. The area of steam piston can be found by calculation if wished.

We have then a pump with 4 inch water pistons and 6 inches stroke, making 30 strokes per minute each side, or 60 strokes per minute in all. Its capacity is theoretically

$$\frac{4x4x\ .7854x6x60}{1728} = 2.6 \text{ cubic feet per}$$

minute. This gives 156 cubic feet per hour, and 9750 lbs. per hour. This gives a margin over the actual requirements of

$$\frac{(9750-8797.5)x100}{8797.5} = 10.8 \text{ per cent.}$$

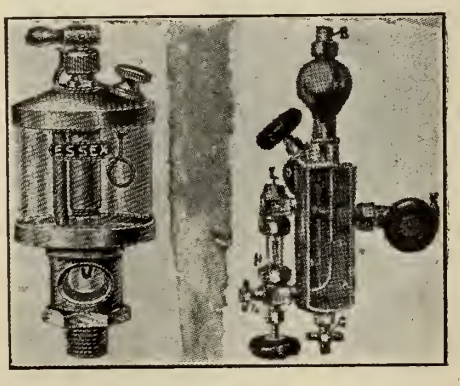
when the boiler is working at 50 per cent. overload.

It is cheaper in first cost to get a pump just large enough to run the boiler at actual rating, but it is far cheaper in maintenance and repair costs, and for reliability, to get a pump large enough to take care of at least 50 per cent. overload. If there is a chance of future enlargements these also should be taken into account when considering the installation of feed pumps.

SIGHT FEED LUBRICATORS

Question:—How would you describe a sight feed lubricator?

Answer:—Sight feed lubricators are of two kinds, those for lubricating bearings and those for lubricating the interior of cylinders and valve chests. The sight feed lubricator for the bearings merely consists of a container for the oil, fitted with a spring needle valve which can be adjusted to permit of the



Sight Feed Lubricators

flow of a definite quantity of oil, and a hollow stem which screws into the bearing and also contains a glass tube through which the oil can be seen as it passes from the container to the bearing.

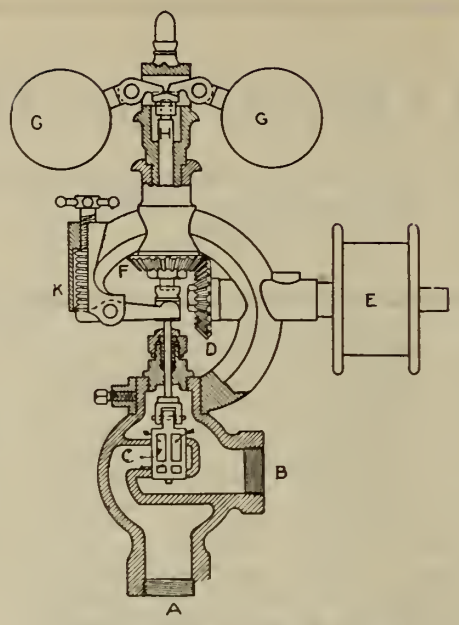
The sight feed lubricator for the interior of cylinders and valve chests consists of a cylinder for containing the oil, a chamber above this for condensing the steam, which is connected to the top of the condensing chamber. A second connection from the side of the lubricator enters the steam pipe through which the oil passes. There is a gauge glass on the containing cylinder to show the amount of oil in it, and a glass through which the oil passes on its way to the steam pipe. The action is simple. The steam connection to the condensing chamber from the steam pipe some distance above the connection for the feed.

When the valves are open communication is established through the lubricator from one connection to other, and the pressure is equalized. There is however a head caused by the water contained in the condensing chamber, and the pipe above it. The water drops to the bottom of the condensing chamber and forces the oil down the small pipe and through the gauge glass and then into the steampipe through the side connection. The chamber is filled with oil from the plug shown on the side, and there is a valve above the condensing chamber as well as on the inlet so that the lubricator can be shut off for filling, cleaning, etc. The valves on the sight feel glass are of the needle type, thus allowing a very small drop of the oil to pass through at a time. The sight feed glass fills with condensation through which the oil globules pass.

THROTTLING OR AUTOMATIC ENGINE

Question:—Will you please tell me through the Question Box what is the difference between a common throttling engine and an automatic engine? Also how would you describe a sight feed lubricator?

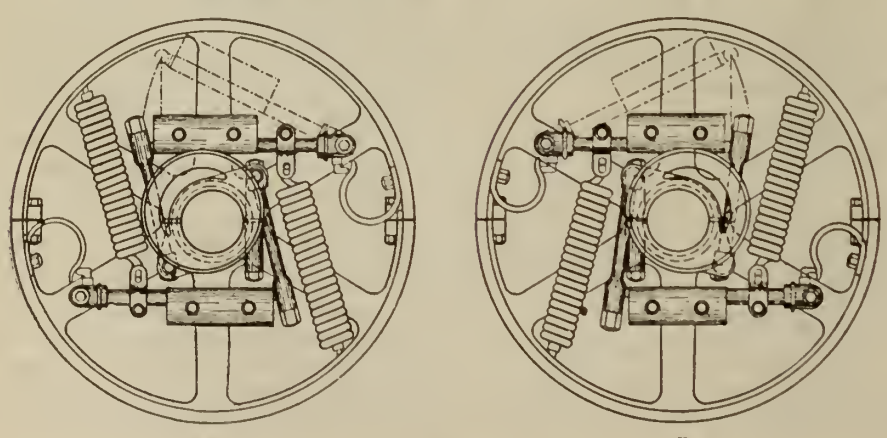
Answer:—In the throttling engine, the governor performs its task by diminishing the opening of the throttle valve which admits steam to the steam chest of the engine. The throttling governor, a cut of which is shown here, depends for its action on the speed with which the balls revolve around the axis, this being governed by the speed of the engine. The governor is proportioned so that at the speed set for the engine to run, the governor keeps the throttle valve fully open. As the speed of the engine increases the centrifugal force of the balls tends to make them increase the diameter of the circle in which they revolve. In so doing, they shorten or draw up the rods to which they are attached, and which are in turn attached to a lever, at the opposite end of which the throttle valve spindle is held by a link, the fulcrum being in the centre. Raising the end of the lever to which the governor is attached, naturally depresses the end on which the throttle valve is held, and



Throttling Governor. A to steam chart. B to boiler.

closes it down an amount corresponding to the height and the lengths of the arms of the lever. The fly ball governor is made in different syles but the principle is the same in all of them. In the case of a Corliss engine, the governor actuates two rods, which in turn move the cams around on the valve spindles making the cut off sooner or later. In this respect the action is different, inasmuch that instead of throttling the steam in the steam pipe, the cut off of the steam valve is altered. The effect of throttling in the ordinary engine is to effect what is called wire drawing of the steam which practically means that not only is the quantity of steam admitted lessened, but its pressure is diminished by the friction of passing through the narrow opening.

In the automatic engine, the governor is placed in the flywheel, and acts through the displacement of weights caused by the centrifugal force generated by the speed of the wheel. As the engine speeds up, these weights tend to move further from their centres, and in doing so affect the cut off in this way:—the eccentric, instead of being fastened to the shaft, is fastened to the arms of the governor, and is free to move around the shaft and in some cases to move across the shaft as well. In the case of the eccentric moving around the shaft only, the effect is to increase the angle of lead of the valve. This results in making the lead earlier, the cut off earlier, release earlier and compression earlier. This means that the admission of steam is less, while the compression is much increased, with the result that the speed is lessened. In this case there is no wire drawing of the steam, it being still at the full pressure in the steam chest, and the full benefit of the expansive power being retained, while the steam which is contained in the cylinder at compression is not lost, but is alternately compressed and expanded. In the case of the eccentric approaching closer to the centre of the shaft, thus diminishing the amount of opening of the ports, while still retaining the expansive properties of the steam. There are numerous forms of shaft governors, but the general principles of them all are similar. The illustration shows one of these forms.



A *B*

Shaft Governor.

BALL CHECK TROUBLE

Question:—I should like to know through the columns of Power House why a new ball check on the feed pipe of the boiler makes an awful humming noise when the pump is in action.

Answer:—Humming of a ball check valve, or chattering of an ordinary flat or mitre seat check valve, is usually experienced when the rate of feed is such that the valve is lifted very slightly from its seat, and kept in a sort of balance by the incoming feed and the pressure from the boiler. A condition arises when this feed forcing itself past the narrow opening of the valve, causes a vibration which communicates itself to the pipe with a humming or chattering sound. As a rule a change of speed of the pump will effectually stop this noise, which can be very unpleasant. It has been our experience with ball valves that it is more difficult to keep them from banging than from chattering. What has been the experience of other engineers along this line?

Another Monthly Statement has been issued by the Canadian National Railways. The President, Mr. D. B. Hanna, has stated that the net earnings for the month of October, 1921, are $1,036,130. Comparing these figures with the September net earnings, which were $500,000, it shows an increase of 105 per cent over last month's total. Figures supplied by the Dominion Bureau of Statistics, at Ottawa, show that the operating ratio published by the Canadian Railways for August was 86.41 per cent., which was a decided improvement over August last year. In August, 1920, the ratio was 98.82 per cent. The improvement was effected by reduction in operating expenses, the greater portion of which was brought about by a $5,118,010 reduction in pay rolls.

Present Status of Coal Carbonization

Carbonization of Coal at Low Temperatures and Its By-Products in Their Various Forms, According to Investigations of the U.S. Bureau of Mines. Read Before the American Gas Association

By JOSEPH G. DAVIES

FOR THE past twenty years an enormous amount of experimental work has been done in this country and in Europe on the carbonization of coal at low temperatures. Most of this work has been carried out on a laboratory scale, or at least on a semi-commercial scale, and only recently have results been obtained that can be used directly by the carbonization engineer. One object in view in the experimental work has been to learn from a purely scientific standpoint more of the composition of coal and its thermal decomposition. Another object has been the discovery and commercial development of more economical methods for processing fuels than the well-known high temperature methods. This paper deals more particularly with the latter phase of the work.

Parr and his co-workers in this country, Stansfield in Canada, Wheeler, Jones, Burgess, Bone and Lewes in England, and Fischer and Gluud in Germany, have been particularly active in research on the scientific aspects of the problem and on the technical application of their results as well. The problem of coal constitution and thermal decomposition is a long way from solution, although considerable progress has been made. Of the chemical constitution of coal, little is known as yet, but the yield of distillation products obtained under fixed temperature conditions, as well as their general nature has been empirically worked out; the actual chemical reactions involved, however, have not been fully explained.

The technical application of low-temperature carbonization is still in its infancy and development has been slow, mainly for three reasons—(1) adequate fundamental knowledge of coal constitution and thermal decomposition is lacking; (2) evolution of suitable retorting apparatus is slow, owing to the low heat conductivity of coal and the consequent difficulty of designing retorts which have appreciable capacity and also the requisite low temperature gradients; (3) a market for the rather special distillation products, however valuable they may prove to be in the future, does not exist and must be created.

Fundamental Considerations

(a) What is meant by low-temperature carbonization?

Authorities differ somewhat as to what is meant by low-temperature carbonization of coal. Parr, (Parr, S. W., and Layng, T.E., Low temperature carbonization and its application to high oxygen coals, J. Ind. & Eng. Chem., vol. 13, No. 1, p. 14, January, 1921) who is interested mainly in converting Illinois coals into smokeless fuel for domestic use, defines low-temperature carbonization as "destructive distillation at temperatures not in excess of 750 deg. or 800 deg. C."

Bone (Bone, W.A., Low temperature carbonization of coal, Gas. Jour., vol. 155, July 6, 1921, p. 31) considers temperatures 550 deg. to 600 deg. C. best for low-temperature carbonization of British bituminous coals. Gluud, (Gluud, W. Die Tieftemperature Ver Kokung der Steinkohle, second edition, 1921, published by William Knapp, Halle.) defines low-temperature carbonization as carbonization within such temperature limits that primary tars only are obtained. He fixes the temperature range at 500 deg. to 600 deg. C. He states further, however, that 800 deg. C. is the temperature at which primary tars begin to decompose appreciably, in which statement he is in substantial agreement with Parr. It would seem to the writer that a logical definition of low-temperature carbonization should specify carbonization under such temperature conditions that primary tars (chiefly paraffins and tar acids) are not decomposed to any appreciable extent, the highest temperature to which either coal or tar is exposed being not in excess of 750 deg. C. It must be considered, of course, that different coals may require slightly different temperature treatment, although Fischer and Gluud found that tar of the same general characteristics was obtained from a large number of bituminous coals when distilled under the same conditions. For the production of the best coke, it is probably best to carry the distillation temperature as high as possible.

(b) Amount and character of products obtained by low-temperature carbonizations:

The figures for yield of products given by technical writers for various low-temperature processes vary so widely that it is hardly worth while to discuss them here. The chief cause for this variation can not in general be explained by imputing to one process greater merit than another, but will usually be found in some variation in distillation conditions unexplained or perhaps not fully understood by the writers. For a given distillation temperature, any process should yield the same quantity of by-products. The following figures are taken from results reported by the most prominent experimenters working on a small scale and under carefully controlled conditions with coals of the same rank and it is believed they represent to a close approximation what should be obtained technically with the right process and proper control.

(1.) Tar oils. The tar oils form what is perhaps destined to be the most important product of low-temperature carbonization technically, since on account of their similarity to petroleum products they can be used largely as substitutes for petroleum oils in the industry.

It is now pretty well established that these primary tar oils from bituminous coals consist chiefly of phenols and hydrocarbons of the paraffin, napthene and olefin series, together with substituted aromatic compounds which are for the most part methylated. According to Gluud (same reference) 10 to 15 per cent of the hydrocarbon portion of the tar consists of pure paraffins, the lighter part of the hydrocarbon portion being richer in paraffins, and the heavier part containing higher percentages of napthenes, unsaturated bodies and hydro-aromatic compounds. The amount of phenols in the raw tar varies from 15 to 50 per cent, according to the volatile content of the coal the remainder being hydrocarbons. The hydrocarbon portion of the tar is very similar chemically to Russian petroleum; it is likewise very complex and only a very few pure chemical compounds have been separated from it and identified. Bituminous coals yield around 10 per cent primary tar. On refining this tar by distillation wth superheated steam, a method which he recommends, Gluud obtains the following products:

Refined products obtained from low-temperature tar from gas coal.

Boiling range (deg. C)	Yield per cent. of tar	Product
20—100 deg.	3	Paraffins from the gas
100—200 deg	10	Light oil
200—300 deg.	12.5	Low viscosity oil (solar oil, motor oil, polishing oil) containing 1% fluid paraffin oil
300 deg.—to dry point	15.0	Lubricating oil (viscosity, V50—20—30 deg. E.) containing 1.5% solid paraffin
	9.0	Red resin.

*Presented before the meeting of the American Co's Association, Nov. 9, 1921, Chicago.

In addition to the above products, 50 per cent. of the tar was obtained as phenolic compounds boiling between 200 deg. C. and the dry point.

The above results agree fairly well with those obtained by Parr, (Parr, S. W., and Olin. The coking of coal at low temperatures with special reference to the properties and composition of the products, Bull. 79, Illinois Engineering Experiment Station), and may be taken as representative of low-temperature tar oils obtained under conditions which are within the meaning of our definition. Their technical application will be discussed later.

(2) Coked residue. The coked residue in general amounts to from 70 to 75 per cent. of the coking or semi-coking coal charged; it is not so hard as metallurgical coke and contains from 10 to 18 per cent. volatile matter. This coke is easy to burn without smoke, ignites readily, and should make an ideal domestic fuel.

It is claimed that coke suitable for this purpose can be made from coking coals unsuited for the making of metallurgical coke. Parr (same reference) claims to be able to make a good domestic coke from Illinois coals of high oxygen content, and samples shown the writer would seem to bear out this claim. The main feature in Parr's process is a preliminary heating to 300 deg. to 400 deg. C., after which the coking takes place for the most part autogenously, due to heat of reaction of the coal undergoing carbonization.

(3) Gas.

Writers differ considerably as to the amount of gas produced, but it is probably safe to assume that the yield for fair gas coals is between 5,000 and 6,000 cubic feet of 650-750 B.t.u. gas, per ton of coal carbonized. Bone (work cited) conservatively puts the gas yield at from 300 to 400 cubic feet per ton. The composition of this gas, according to Lewes (Lewes, V.B., The carbonization of coal, D. Van Nostrand Co., 1917) is approximately as follows:

	Per cent.
Hydrogen	27.5
Saturated hydrocarbons	
Methane 48.0	
Higher members 10.1	58.1
Unsaturated hydrocarbons	3.0
Carbon monoxide	7.3
Carbon dioxide	2.5
Nitrogen	1.6
Total	100.0

Uses to Which Low Temperature Products are Especially Suited

One must discount to some extent the claims of exponents of the various low-temperature processes as to the special uses to which their products suited and to what extent they are destined to displace other materials for which the demand is well established. As a matter of fact, there is now no well established demand either in this country or abroad for low-temperature products as such or as substitutes for other materials. The writer believes that development, though it has been slow and beset with technical difficuties, has been in advance of the demand for materials produced. Any process, in order to be a success financially, must now bear the burden of creating a demand for its products, and this has been the chief reason for slow development of low-temperature methods up to the present time. As for the future, perhaps in the near future, there is every reason to believe in the success of a low temperature carbonization industry. The main factor which will bring this about is the rapidly increasing demand for liquid fuels of all kinds. Every resource will be drawn upon, and coal, particularly coal of low rank, will probably be for a long time among the cheapest of raw materials. It may therefore pay in time to "process" coal for oils as the main product. So long as there is no definite demand for the special products which "processing" will supply, one might as well think of going to the trouble of refining cast iron; making a fine grade of tungsten steel, for example, to use for window weights, as to think of "processing" coal. This of course does not apply to well established methods for processing coal where gas or metallurgical coke are the special products sought.

It must not be expected that the profits to be derived from low-temperature processing of coal will be large. To quote Sir George Beilby (From the James Forrest lecture on "Fuel problems of the future" delivered June 28, 1921, before the British Institute of Civil Engineers), Director of the British Fuel Research Board, "Low-temperature carbonization can only be established on a sound commercial basis with low operating costs and a very moderate margin of profit."

(a) Uses for the tar oils: The refined light oils from the tar may be sold as motor spirit, for which there are good prospects of ever-increasing demand. The amount of oil available for this purpose may be taken at around 3 gallons per ton of coal carbonized, the exact amount depending upon the volatile content of the coal. There is a question in this connection, as to how far the refining of oils of this character must be carried to fit them for use in motors. It is possible and even probable that refining methods other than those now used for petroleum, and high-temperature light oils, may be developed which will release a larger proportion of the low-temperature light oils as refined motor spirit stock than can now be counted on. The Bureau of Mines is just at present working on the problem of motor spirit refining in connection with oils similar to low-temperature light oils. The heavy low-temperature oils, as previously indicated, consist chiefly of acids (phenols) and neutral hydrocarbon oils. The phenol content is high, it amounts as much as 50 per cent of the total tar yield of 24 gallons per ton of coal, according to Gluud (work cited.) He also finds that the higher the total tar yield, the higher its content of phenols.

One large use for low-temperature tar acids will doubtless be in connection with timber preservation.

According to Coffin (Coffin, F. P. Uses for low temperature tar oils, Gas Age-Record vol. 48 No. 3, p. 97, Aug. 6, 1921) between 90 and 100 million gallons of such oil were used in 1913 in this country for that purpose, and two-thirds of this amount was imported. Evidently there is a present demand for low-temperature tar acids, and the only question remaining to be decided relates to their suitability for the purpose. Coffin states that they are even better than high-temperature tar creosote. Other uses mentioned for these tar acids are, insecticides (including dipping oils for live stock), disinfectants, and flotation oils. It is not clear that there is an appreciable shortage in the present supply of these chemicals, although a growing demand may probably be assumed.

According to Gluud, the heavy hydrocarbon oils, and in fact crude tars from which the acid is not removed, have found extensive use in Germany as lubricants during the war. He adds that even now most low-temperature tar produced is used directly for that purpose, although really high-grade lubricating oil can be made from the crude tar on distilling with steam and removing the phenols.

The total tar oils, with very little refining, may be used as fuel oils, although demand for them for other purposes should preclude such use. Armstrong, (Armstrong H. L., low temperature carbonization, Gas World, vol. 74, No. 1902, p. 12, January 1, 1921) of the Low Temperature Carbonization, Limited, states that at the Barnesley plant fuel oil complying with the Admiralty specification, is made by steam-distilling the crude oil till sufficient light oil is removed to bring the remainder within the Admiralty flash point specification and then decanting the water.

(b) Uses for the coke: it is claimed both in this country and in England that low-temperature coke is an ideal fuel for domestic heating. This seems reasonable, particularly in view of the quality of coke obtained by Parr from coals rather inferior from the coking standpoint. It should be feasible and profitable to coke low-rank semi-coking coals primarily for solid domestic fuel and light oils. However, the American public is slow to take up the use of coke, and the same seems to be true in England. The public aversion to coke may be due partly to prejudice and partly to lack of knowledge of the best ways to burn it; the writer is inclined to believe both factors are responsible. In any event, the public must be educated to its use before there will be a good demand for low-temperature coke for domestic heating.

(c) Uses for the gas:

The small amount of surplus gas available for distribution (at most 3,000 cubic feet per ton of coal carbonized), makes the gas a product of lesser importance. It is, however, of good quality and suitable for distribution for domestic heating.

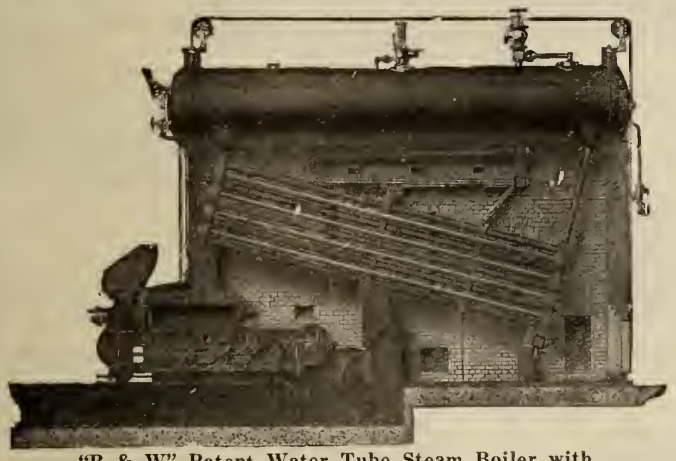
"B & W"

Marine and Land Type

Steam Boilers

Made in four types, all specially designed for the rapid, economical and safe generation of steam up to the highest pressures.

Typical installation of "B & W" Boilers and Mechanical Stokers.



"B & W" Patent Water Tube Steam Boiler with Superheater and Mechanical Stoker.

"Lagonda" Boiler Tube Cleaners

are valuable accessories for keeping the tubes free from scale. Cleaners are Water, Air or Steam driven and designed for use in all sizes of tubes over 2-inch diameter. Equipped with different heads and a supply of cutters, pins, etc.

Accepted the World Over as the Safest Method of Steam Generation

Every advantage that can possibly be obtained from a boiler hinges on that one word "safety." A boiler that is safe is also economical; for only where safety exists can high pressures be obtained with rapidity. "B & W" Boilers are accepted as the world's standard of safety and efficiency because the construction avoids all unequal strains—because all joints are removed from the immediate action of the fire.

The design of "B & W" Marine and Land Type Boilers includes three important elements—(1) **A series of Inclined Water Tubes** over the furnace in which the water is quickly raised to a high temperature. (2) **A Horizontal Steam and Water Drum** which keeps the water in rapid circulation in one direction and maintains a uniform temperature. (3) **A Mud Collector** which collects all foreign matter.

In addition "B & W" Boilers are easy to clean, easy to erect and possess sufficient durability for years of care-free service.

Full technical information is contained in the "B & W" Boiler and Superheater catalogue. Your name and address will bring a catalogue.

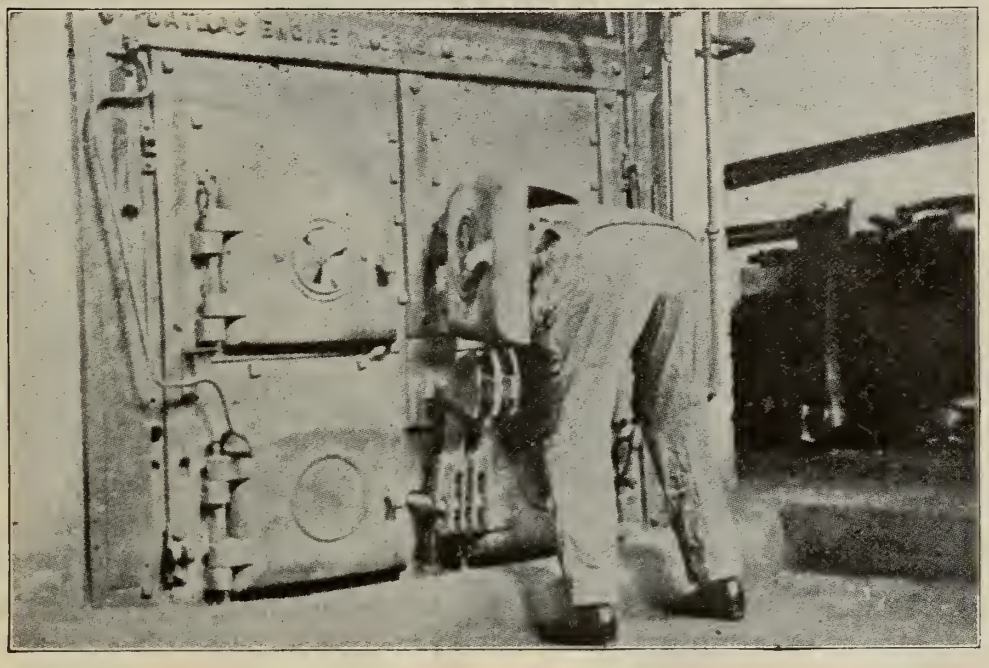
Try Our Service



The illustration above shows one of our representatives about to investigate the "in'ards" of a boiler. Whatever your requirements, whether you contemplate a small repair job or the installation of a complete boiler setting, let us know, and our nearest representative will show you how

PLIBRICO JOINTLESS FURNACE LINING

can best be applied, and will help you apply it.
No matter how inaccessible your plant, or whether you will require one drum of PLIBRICO or a carload, we of the Jointless Fire Brick Company are ready to give you our best service. Try us.
PLIBRICO is a plastic furnace lining that when molded into shape and properly baked and vitrified forms a setting that is solid as rock and resistant to heat up to 3,100° F. No skilled labor is required, but PLIBRICO can be applied by any man who can wield trowel and mallet.
Ask for our book L-43 on "Modern Furnace Building." It contains valuable information.
PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

Distributors: Beveridge Supply Co., Ltd., Montreal, Que.; Shell Bar Boico Supply Co., Ltd., Toronto, Ont.; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply & Fuel Co., Winnipeg, Man.; Gorman's, Ltd., Calgary, Alta.

JOINTLESS FIRE BRICK CO.
1142 CLAY STREET, CHICAGO, ILL.

JONES STOKERS

POWER interruptions will not, and should not, be tolerated in modern plants. That is why Jones Stokers are favorites for plants of practically every size. Their rugged simplicity makes shutdowns for repairs next to impossible. Fuel and air are automatically controlled; little attendant labor is required.

In the "A-C" (Automatic-Cleaning) type, fires are automatically cleaned.

Retorts may be individually controlled —an exclusive feature.

Clinkers do not form on bridge or side walls.

The under-feed principle of combustion (originated in Jones Stokers) insures maximum economy of fuel at all loads.

These, and other distinctive features that make the Jones Stoker "pay for itself—then pay dividends," are covered by the new catalog.

Have you your copy?

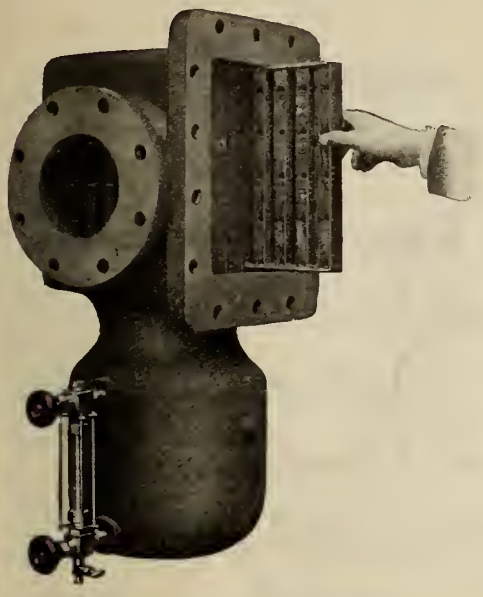
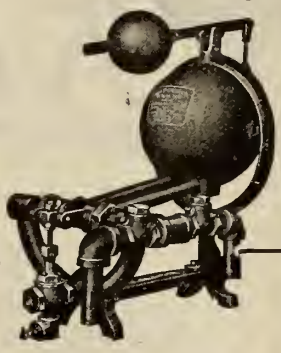
The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co. of America are made available for Canadian power users. Thus this strictly Canadian Stoker is backed by world-wide experience and unequalled engineering ability.

BUNDY Steam Traps and Separators



Are the Scientific Answer to Engineering Problems!



THE BUNDY OIL SEPARATOR

is a device perfected to the finest degree possible. In actual service it is the only type that fulfills the following requirements. Insures maximum removal of oil from steam. Prevents steam from again picking up oil. Maintains high efficiency because it is easily cleaned.

Bundy Oil Separators and Steam Traps can be obtained at any of our branch agencies. Drop a line for further particulars.

Return Trap

Bundy Steam Traps can be safely bought on their rated capacity. They are made of cast iron and semi-steel—built for long service. Rigidly tested under actual working conditions.

Agencies at: Quebec, Halifax, St. John, Winnipeg and Vancouver."

John Crane

Eight Years of Packing Service
JOHN CRANE Flexible Metallic Packing Shows Greatest Results in Constant Service

Eight years ago Chief Engineer, N. Gross, of the Standard Oil Building, Chicago, installed JOHN CRANE Flexible Metallic Packing in the boiler-feed pump pictured below. Mr. Gross reports packing and pump in good order after eight years and has standardized JOHN CRANE on all service.

JOHN CRANE holds this long service record because of its scientific, practical construction. Made of babbitt foil and graphite, it brings Packing science "The Babbitt-bearing Principle," and while responding to the slightest pressure of the gland never dries out, but remains compressible and will not score rods.

New Ice Breaker to be Built; Machine Tools Are Still Quiet

MONTREAL, December 1st.—This week has seen the placing of another large contract with a local firm. The Hon. C. C. Ballantyne announced on the evening of the 24th, that the lowest tender for the proposed new Government ice breaker was that of the Canadian Vickers, Ltd., and that the contract would be awarded that firm shortly. It will be remembered that an ice breaker was constructed for the Government in 1914 but owing to the conditions existing at the time, it was sold to the Russian Government. It has been felt that a new ice breaker would be constructed at an early date to replace the original one. Figures on the ice breaker were obtained some eighteen months ago and it was found that it could not be constructed at a reasonable cost. The lowest bid at that time was in excess of $2,000,000. The recent bid of the Canadian Vickers firm is $1,580,000, at which figure the contract will be placed. By waiting the year and a half it has been able to place the contract for a sum of $700.000 less than the tenders received early in 1920. The contract has been let at a most opportune time as there is a great deal of unemployment in the class of labor that will be employed on the ice-breaker. The breaker will be employed on the St. Lawrence and through its operations it is thought that considerable time can be added to the length of the navigation season. The contracts that have recently been placed for work of various natures in the engineering field have done a great deal to restore plants to their usual activity. The steel for the new Mount Royal Hotel has been delivered and is being rapidly passed into the Dominion Bridge Co. shops. It is announced that the erection of steel will be started on Dec. 15th. The sale of steel, sheets, bars and pig iron seems to be about as active as has been usual for the last few weeks. Generally, the whole steel and iron business is in a very satisfactory condition when all things are considered. The placing of the large orders has given consumers and shop men a great deal more confidence in the markets and will have a good influence in starting 1922 off at a good pace.

For the past few weeks there has been very little change in the volume of business. From some quarters a slight gain is reported, while in a few instances a slight decrease is reported. On the whole there is probably a net gain. There is a

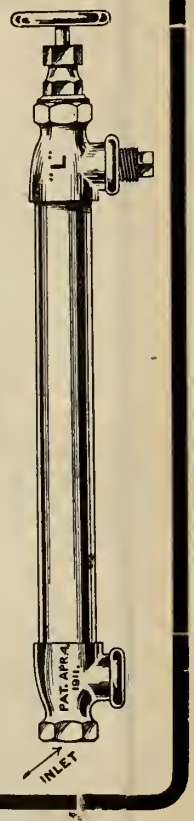
MONTREAL, CAN.

If your dealer does not sell it, write direct. No. 2



CAST IRON STORAGE TANK

Storage tanks of cast iron are rapidly growing in favor because of their permanent, sturdy structure, low maintenance costs, long life, ease of erection and correct engineering design.

The American Cast Iron Storage Tank has just been developed by the Conveyors Corporation of America, Chicago. It has been carefully tested under a wide range of conditions and is a pronounced success.

The tank was not designed to hold liquids but for dry storage purposes. Among materials that can be successfully stored in this tank are ashes, coal, building materials, foundry supplies such as coke and sand; chemicals and allied raw materials such as granular fullers earth, gilsonite, kieselgur, bauxite, potash, animal charcoal,—in fact all loose, bulky materials that are ordinarily stored in silos tanks, hoppers and bins.

Some advantages of the cast iron storage tank are its long life and low maintenance costs. Cast iron tanks resist corrosion, abrasion and rust. They are easy to erect, and unskilled workman are able to put this tank together, so simple is its construction.

It is cylindrical in shape, erected on a 5 inch reinforced concrete slab which is supported on a structural base or tower, built up of standard fabricated structural shapes.

The body of the tank is built up of cast iron radius plates, held vertically between cast iron H-sections. The tank can be built to any convenient height.

The Conveyors Corporation has issued a folder giving illustrations and specifications of the American Cast Iron Storage Tank. Copies will be sent free on request.

A MODERN TRANSFORMER SUBSTATION

The Glory Sub-Station of the Penn Public Service Corporation of Clearfield, Pa. is an example of the most up-to-date methods of construction of transformer sub-stations. This sub-station receives power from the new Seward Power Plant, which is located on the Conemaugh River near Seward on the main line of the Pennsylvania Railroad, about ten miles west of Johnston. The 66,000 volt transmission line extends in a north west direction to the Glory Sub-Station about nineteen miles distant, transmitting a large block of power from the Seward Plant to Clearfield, Indiana Counties.

The sub-station building is a structure of concrete, brick and steel, housing the control switchboard and auxiliary devices. The transformers, electrolytic lighting arresters and high voltage circuit breakers are all located out doors, the high voltage buses being suspended from a steel overhead structure of up-to-date design.

The main step-down transformers consist of four-2500 kv-a., single phase oil insulated, self cooled units of the radiator type. Three of these transformers are normally in sevice, the fourth being held as a reserve. The transformers are mounted on wheels and by means of transfer trucks can be quickly removed from the outdoor switch yard for repair or shipment. The secondary side of the transformers delivers 22,000 volts to the low voltage busses, from which feeders distribute the power to various points in Indian and Clearfield Counties.

These transformers together with the oil switches, lightning arresters and auxiliary equipment were furnished by the Westinghouse Electrc & Manufacturing Co.

ANNOUNCEMENT

The Coppus Engineering Company of Worcester Mass., have opened a branch office at 315 Mappin Building, Montreal. This branch will be in charge of Mr. W. L. Hunter, and will look after the territory in Eastern Canada, including the Province of Quebec. The various lines manufactured by the Coppus Engineering Company will be handled by the branch office, and include several types of blowers, turbo pumps, and turbines.

Is Canada's Frozen North A Myth ?

Vilhjalmur Stefansson, the Canadian explorer-author, in an article in MACLEAN'S MAGAZINE for December 15, entitled "Northward the Course of Empire," asserts that the stories of intense cold and other unendurable conditions in the sub-Arctics of Canada are all pure poppycock. He points out in this, the first of a series of four articles, that before the trans-continental railways were built, the same assertions were made regarding the fertile Prairie regions of Manitoba, Saskatchewan and Alberta that are now being made about the sub-Arctics.

Every Canadian interested in the development of his own country should be versed in the potentialities of the "wider Canada" beyond our present horizon of development.

The Christmas number of MACLEAN'S MAGAZINE, out

December First

is beyond doubt the finest in its history. There are contributions from such writers as Leacock, Agnes Laut, Alan Sullivan and Archie McKishnie; but MACLEAN'S did not gain its reputation by going after "names," and there are also other articles by lesser-known writers, including a delightfully poignant story by Frances Beatrice Taylor—her very first.

A Remarkable Offering of Timely Articles and Entertaining Fiction

Little Theatre of the Hills—Canada—by Agnes C. Laut: A plea for the development of Canadian national consciousness. Are we making the best of our national virtues and characteristics?

Frederick Niven: A Canadianized Englishman has a few remarks to make about those newly arrived Old Country men who come out to Canada to make good and then indulge in bootless criticism.

Little Ukraine in the Canadian West—by Mrs. Charlotte Gordon: Something about one of our alien colonies which does not desire to remain alien.

Age and Occupation Determine Food Needs—by William Fleming French: An authoritative food article which answers the question "What Should Henry Eat?"—no matter what age Henry may be.

Stephen Interviews Leacock

By Stephen Leacock: Canada's premier humorist describes what happened when he was interviewed on his arrival in London; tells how the English questions left him all at sea because he missed the usual "bromides."

A Startling Review

"Can the White Race Endure in the Bright Sunlight of Western Canada?" Charles H. Huestis, M.A., D.E., here discusses the effe of light and warmth on our Western people.

Twenty other reviews from British, French, American and Canadian current literature.

Is All Prayer Answered?—by Marshall P. Talling: A timely and entertaining article by a Canadian who has made a special study of prayer, what it means and what it achieves.

The Efficiency Christmas—by Zoe Beckley and Joseph Gollomb: A yuletide story with a laugh and a sob, a thrill and a heart-tug, about real people with the right sort of kiddies.

The Case of Jean Louis—by Maurice Le Blanc: The third of the Arsene Lupin series, by the master teller of fast-acting mystery tales.

The Ladies' Chain—by Alan Sullivan: A follow-up story on one of the most craftsmanlike pieces of fiction ever published in Canada, "Linen Sheets," which appeared a few months ago in MACLEAN'S.

The Usurper—By Archie P. McKishnie: The story about a lynx who was victorious in his battles with other savage things in the wilds and then challenged Man.

Pipes Over the Water—by Frances Beatrice Taylor: Three experienced journalists read this story before publication in MACLEAN'S and each voted it one of the most remarkable little stories of its kind he had ever read.

Mostly Sally—by Pelham Grenville Wodehouse: A big slice of the funniest thing which Wodehouse has written since "The Little Warrior."

The Yellow Streak—by Valentine Williams: The concluding instalment which unfolds the hidden-to-the-last secrets of this enthralling mystery story.

Check the Dollars You Burn!

Do you know how many of the dollars you burn are actually invested in heat—and how many are wasted?

Of course you know how many tons of coal you buy. And you probably know how much heat that coal contains—you can get a B. T. U. analysis from any chemist. But do you know the amount of heat you get out of that same coal?

There is only one dependable way to calculate the value of your coal—what quantity of water is evaporated by a ton of it? A

YARWAY-LEA V-Notch METER

will give you the records you need to determine the degree of economy with which your boiler room is operated and will enable you to prove this to the management. It is a simple, durable, scientific machine, providing permanent records guaranteed accurate within 1½% at high and low rates of flow.

There are many other uses for the Yarway-Lea Meter besides in the boiler room. Booklet L-40 goes into details. Where shall we send your copy?

Operation: Liquid is admitted through control valve 8 to weir chamber 7. As level of liquid rises and falls, flowing through V-notch 6, float 5 connected to rackrod 9 also rises and falls, indicating flow in inches of head on scale 1, simultaneously showing rate of flow in pounds or gallons on cam drum 2, with permanent graphic chart record for any period of day on 24-hour chart 3. Integrator 4 gives record of total quantity of liquid handled since starting operation.

Bright Spots In The Industrial Outlook

NO. 5

A LARGE business organization in the United States recently sent out a circular in which the following occurs: "No really live business man will follow the rest of the 'sheep' and say 'there is no business in my line.'

"There is business in every single line of industry today, barring none. True, in some lines the opportunities are less than in others, but there is absolutely no excuse for not getting your share."

This statement fairly "hits the nail on the head." If each manufacturer or merchant will realize that, no matter how dull business may be, there is at any rate enough business going to keep him fully employed, and if, realizing this, he will go after the business with every ounce of energy of which he is capable, he will not only be able to maintain his volume of sales at its normal level but will uncover fresh business which will enable him in spite of dull times to emulate the example of those merchants details of whose success in this respect we have already given, and to whose number we make a further addition below.

The Universal Knitting Co., Vancouver, has in the past twelve months doubled its floor space and doubled its capacity, and, according to Mr. A. C. Cohen, the manager, is employing more operatives than ever before. Full time has been worked all the year. The volume of garments manufactured and sold has been 50 per cent. greater than last year. The policy followed has been to make prices as close as possible but in no way to allow quality of goods to suffer.

The Williams Tool Corp., of Brantford, Ont., report that business last month was double that of the previous month and that they are doing much better business than a year ago. Asked to account for this, Leslie H. Hall, sales manager, said, "We know our machines were selling at a fair price, so we decided that more aggressive methods of salesmanship were required. We have spent considerable money on educational and advertising literature."

Bovril, Ltd., report that sales of Bovril in Ontario during 1921 show an increase of 75 per cent. over those of last year. Sir George Lawson Johnston, president, who was lately in Canada from the Old Country, stated that their sales throughout the world are ahead of last year.

Willards' Chocolates, Ltd., are considerably ahead of last year in their sales. Their returns for October show an increase of 32 per cent. over the same month last year. This they attribute to consistent advertising and hard work.

The King Suspender Co., Toronto, sold out their stock at sharply reduced prices last May. They then manufactured quickly and well with a low-cost material. A strong advertising campaign was launched and nearly the whole staff were sent on the road. The sales staff was increased as it was realized that, with dealers buying from hand to mouth more calls were necessary. The plant is working full time and two auxiliary plants in Toronto and two in Montreal are adding to the output. The company is two months oversold in neckwear and has not taken orders for three weeks. Business in dollars and cents during the past three months has been more than last year; while, owing to lower prices, the quantity of goods sold is twice as great.

The Sherwin-Williams Co. of Canada state that their business shows a substantial increase in turnover as compared with last year despite the fact that there has been approximately a 25 per cent. decline in paint prices. W. S. Fallis, vice-president, attributes this partly to more aggressive selling and the lower prices.

This experience is more or less that of the other paint companies who practically all report increases in volumes of sales although the cash receipts are not increased in proportion owing to the reduction in price. The success of those employed in this particular line of business is undoubtedly due in no small degree to the vigorous paint advertising campaigns which have been organized by the manufacturers.

The Supplee-Biddle Hardware Co., of Philadelphia, with the help of advertising and increased selling effort and by turning the office staff to selling, have more than maintained the volume of sales. In 1920, says W. B. Munroe, president and general manager of the company, business was greater than it had ever been, and December completed the 63rd consecutive month of increased sales. This year the total volume of sales will exceed last year with a volume in dollars that is nearly 24 per cent. greater than any year except 1920. All this business has been gained by hard, persistent sales effort and can be directly traced to ideas which had their inception in the office among the so-called "non-producers." Every part of our organization became a selling unit from the president on down to the youngest office boy.

You can send your sales message throughout Canada from Coast to Coast by means of the following MacLean publications, all of which are members of the Audit Bureau of Circulations. Information regarding circulation, advertising rates and fields covered will be furnished on application.

"A Valve in the Line is worth Two Under Repair"

Unless a valve is positively dependable and will remain tight for long periods without attention it represents a poor investment.

Pratt & Cady Renewable Valves are a worth-while economy in times where every effort is made to reduce the cost of doing business. When after long hard service or because of scale, or other similar substances in the line, leaks develop, the worn parts can be repaired without removing the valves from the line and in minimum time.

Gate valve wedges are reversible and the discs of globe, angle and check valves, as well as seat rings in all types of valves, are renewable. No tool more complicated than a spanner wrench is needed to make the replacement.

Pratt & Cady Valves are economical in both first and final cost. You cannot afford to instal any other kind.

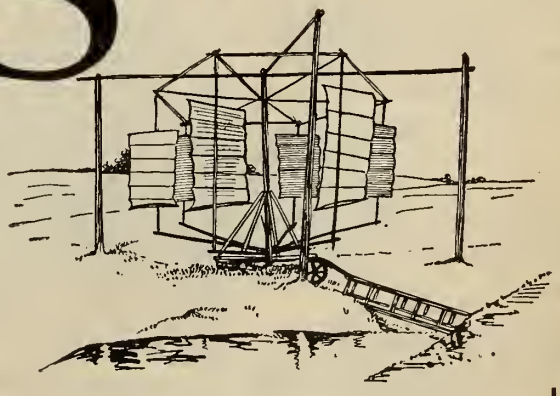
PUMPS

The Chinese Windmill is almost as peculiar as it is primitive.

The ancient Chinaman didn't believe in doing anything he could get natural forces to do for him. In this peculiar windmill pump—for pumping salt water—the wind drives the mill, the mill drives the pump, and the sun does the rest, by drying out the salt. In this way, the Chinese "manufactured" great quantities of salt in a very cheap way.



American-Marsh Pumps are economical—in a modern scientific manner. They have no unnecessary parts—no internal stuffing boxes, no tappets, no slide valves. Write for Bulletins.

CHAIN WHEELS
The Mason Regulator & Eng. Co., Ltd. Montreal.

Speed, Safety and Durability

These are the characteristics of YALE SPUR GEARED CHAIN BLOCKS that make them popular in power plants.

Big fellows for placing machinery in position and little fellows for lighter work, are all made on the same high standard. With a continuous hand chain guide, the hand chain won't gag or foul from side pull or high speed.

YALE Blocks will give you service.

Brownhoist Steel Plate Trolleys

either plain or geared should be used with a YALE chain block.
Small sizes with bronze bearings, two ton and over with roller bearings and with four wheels set at the correct angle. An easy running, safe, durable trolley and fit to be used with YALE chain blocks.

HEPBURN
Steam Pumps

Packed Piston Type for Medium Pressures

This patent pump is intended for Tank and General Service purposes. On such work it gives exceptionally efficient service due to the long regular strokes, accessible valves, self-draining feature and absence of all tappets or levers. It is worthy of note that the self-draining feature, exclusive with Hepburn Pumps, is an important factor in saving steam.

Before you purchase Pumps, Vertical Engines, Cranes, Power Presses or Castings talk it over with us.

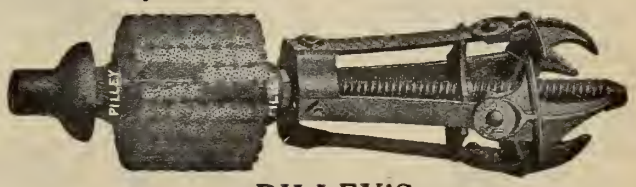
WATSON & McDANIEL CO.
No.146 N. 7th St., PHILADELPHIA, Pa.

The Simplest and best cleaner on the market is



PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.
Manufactured by

PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.

Jenkins Valves

Designed And Constructed To Stand Considerable Abuse

Fig. 106
JENKINS
BRASS GLOBE VALVE

The quality of the metal used in the making of genuine Jenkins Valves and the careful way in which the weight is distributed assure lasting and efficient service—always.

Even where many different and sometimes careless hands manipulate them, Jenkins Diamond Marked Valves stand the test. The little bit of extra pressure, so fatal to cheap and inferior valves, leaves a genuine Jenkins entirely unaffected.

There's a Jenkins Valve for every Service. Supply Houses everywhere sell them. Look for the Diamond Trade Mark when buying—it guarantees the genuine.

Catalog No. 8 free on request.

D.K.McLAREN'S

Genuine British Oak Tanned LEATHER BELTING

GENUINE OAK

The Genuine British Oak Tanning process is the most efficient method known for producing belts that wear. Look for this trade mark.

From the Backs of the Choicest Steers

From a selection of the finest hides obtainable only back portions that are absolutely flawless are used. When this is British Oak Tanned it produces a belting so tough and durable that slippage and power loss are reduced to a positive minimum. If you want to know what this belting is accomplishing for others, write us and get the facts.

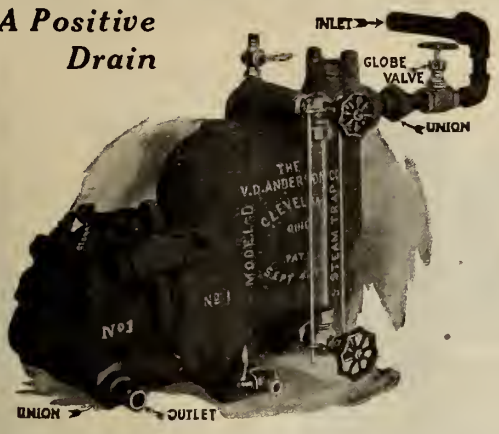
A Positive Drain



The **Anderson Model "D"**
STEAM TRAP

To have dry pipe lines there is no more positive drainer than the Anderson Model "D" Steam Trap. This reliable device stays tight under all conditions. Its immense usefulness is apparent by its automatic adjustment for all pressure variations. It disposes of condensation as fast as it accumulates in steam coils, jackets, radiators, etc. Does not reduce pressure. All parts machined to solid gauge, ensuring absolute accuracy.

Our catalogue describes fully the many excellent features.

THE TIME TO ADVERTISE

ADVERTISING space is like stocks and bonds; it is a better purchase (i.e., will yield more) if bought at the right time. The right time is near the bottom turn of the market, when conditions are improving and we are firmly started on the long rise to real prosperity.—*Printer's Ink.*

LABRIDE Coal Handling
EQUIPMENT
—Saves the Wages of a Gang of Men

Why pay out wages for a gang of men to move coal, ashes, gravel, etc., when one man with a LABRIDE BRIDGE can move it in a fraction of the time, and guarantee a better job? LABRIDE EQUIPMENT consists of a moving bridge traveling lengthwise of the storage space and a bucket trolley traveling crosswise on the bridge, thus every square foot of storage space is covered with a minimum of movements and time. Capacity from 60 to 90 tons per hour. Write or wire for particulars.

IN ENGINEERING CIRCLES

It is the operating engineer who most appreciates reliability.

Hours spent renewing rod packing and replacing gaskets, often in inaccessible places, have proved to him the fact that quality is the main consideration when purchasing packing. Added to this is the saving due to minimum rod friction and leakless joints.

On your next order specify GARLOCK, the packing of world-wide reputation and known reliability.

Morrison Steam Goods

Are You Spending *Enough* or *Too Much* on Your Steam Specialties?

The fact that through not spending enough we often spend too much is true of many business investments. It is especially applicable to the subject of Steam Specialties. Plant owners who fail to spend enough time investigating or who do not spend enough money to get a reputable product, invariably spend too much in the end. For over fifty years now MORRISON'S STEAM SPECIALTIES have been enabling manufacturers to derive unfailing service without spending too much of either time or money. Ask for catalogue.

Let Us Hear from YOUR Plant Today

All over this country of ours plants large and small have been making their furnace linings and boiler settings of

PLIBRICO
JOINTLESS
FURNACE LINING

Almost invariably a first installation has called for a second and larger installation. Why? Because PLIBRICO, pounded into place while plastic, smoothed, and properly baked and vitrified, **always gives satisfaction.**

Where laid-up fire brick is used, trouble usually starts at the joints—mortar crumbles, clinkers adhere to rough and broken edges and when removed often take a brick with them. Result: wasted fuel, incomplete combustion, lowered production.

PLIBRICO, being smooth and jointless, escapes these troubles. A PLIBRICO arch will outlast laid-up fire brick three times—and with no **shutdowns for repairs.**

And PLIBRICO baffles are unexcelled. No tiles or special blocks are necessary. PLIBRICO forms one-piece jointless baffles that are absolutely gas tight and are unaffected by contraction and expansion. No short circuiting of valuable gases when PLIBRICO is used.

Our booklet L-49 on "Modern Furnace Building," shown at the right, tells all about PLIBRICO. Send for it to-day or ask to have our nearest representative call.

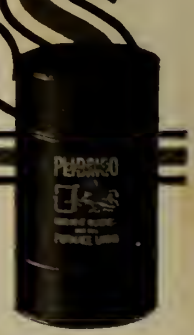
PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

DISTRIBUTORS:—Beveridge Supply Co., Ltd., Montreal, Que.; Shell Bar Bolco Supply Co., Ltd., Toronto, Ont.; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply & Fuel Co., Winnipeg, Man.; Gorman's, Ltd., Calgary, Alta.

"Modern Furnace Building" shows the best methods of installing and repairing all types of boiler settings.

This is the book of valuable engineering data. Send for it to-day. It is yours.

JOINTLESS FIRE BRICK CO.



1142 CLAY STREET, CHICAGO, ILL.

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

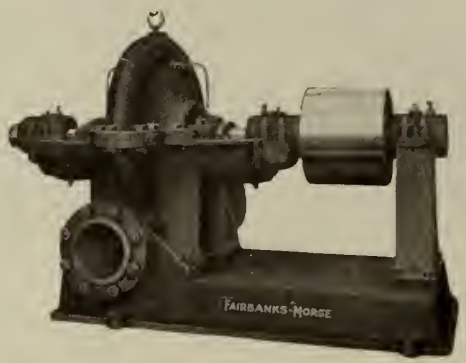
The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

Waterous

BRANTFORD, ONTARIO, CANADA

Fairbanks-Morse Centrifugal Pumps are giving continuous service



Fairbanks-Morse Centrifugal Pumps are reducing pumping costs wherever they are installed. They can be depended upon to operate quietly and satisfactorily and complete changeability of parts facilitates repairs. Driven by any motive power, they will show a saving in pumping costs over other pumps of the same capacities and pressures.

They withstand overloading and the emergencies that good pumps must meet. They are especially recommended for service far removed from the repair shop.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Fisher Tank Controller
(Type 27)

Accurate Level Control For Your Storage Tanks

Any desired level of liquid in your tanks or reservoirs may be accurately maintained with the

Fisher Tank Controller
(Type 27)

It is built for use on closed tanks. It consists of a Fisher Balanced Lever Valve, connecting rods with turnbuckle, bell crank, stuffing box and seamless copper low-pressure float.
It can be used in numerous ways. It will control steam supply to pump according to accumulation of condensation in receiver tank. It will control pump so as to maintain a certain level in tank and it can be installed on waterline to control water level in tank or the outflow where tank is discharging independently into sewer or against no pressure.

Fisher Float Valve
(Type 17)

is an automatic valve especially designed for open tank purposes. Made of the highest grade materials and with characteristic Fisher accuracy and fineness of workmanship, it will render perfect service for unbelievably long periods of time.

Bulletin 401 contains complete information and installation sketches of these devices. Write for your copy to-day.

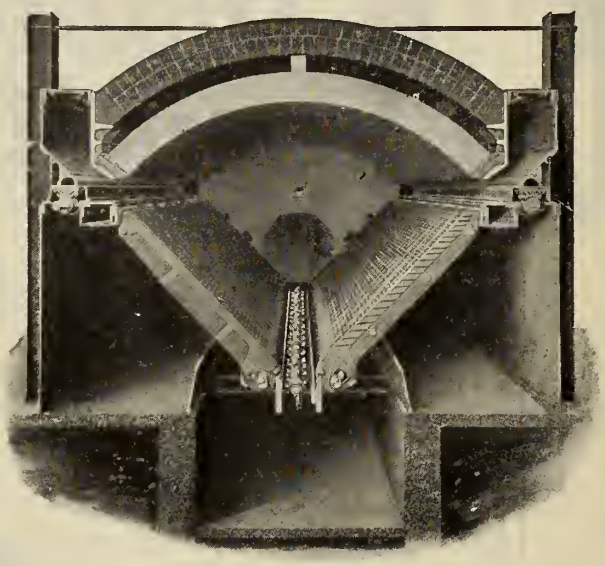
MURPHY AUTOMATIC FURNACES



For Any Boiler
50 h.p. and Up

Any boiler from 50 h.p. and up, can be equipped with the MURPHY FURNACE. The **smaller plant** can therefore enjoy all the economical advantages of fuel and labor savings **without resorting** to forced draft.

To-day over **6000 boilers** are fired by MURPHY FURNACES. You will find them used in nearly every branch of the industry from hospital to industrial and central station service. MURPHY FURNACES "burn any fuel that has heat in it." They double the output of the plant "without one penny for draft."

Our Catalogue "HM-12" shows how MURPHY FURNACES can be installed under any type of boiler—50 h.p. and up.

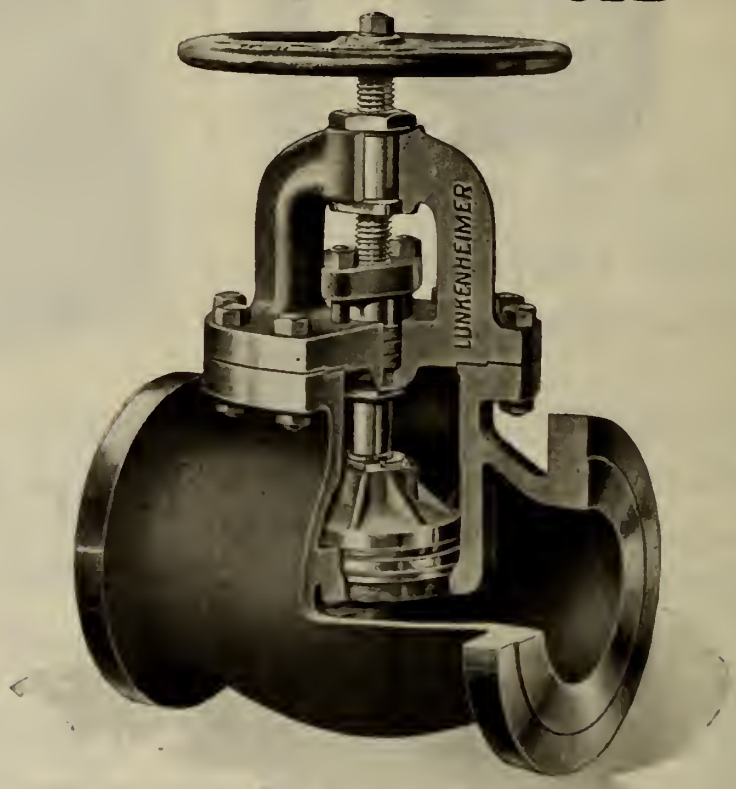
LUNKENHEIMER

Globe, Angle, Cross and Check Valves



Extra Heavy, Fig. 884.

Standard, Fig. 1123.

Service economy—long life with a minimum cost for upkeep—is the dominant factor which has led to the selection of LUNKENHEIMER Iron Body Valves as "standard equipment" in many leading plants.

Their success in service is the direct result of the combination of correct design with proper materials and the Lunkenheimer method of manufacture.

LUNKENHEIMER "Valve-iron" and Lunkenheimer "Valve-bronze" are formulated especially for valve service and the Lunkenheimer method of manufacture insures dependable results under prescribed operating conditions.

The line embraces a variety of types and sizes in Standard and Extra Heavy Patterns for pressures up to 125 and 250 pounds respectively, whose performance and durability fully measure up to the Lunkenheimer high quality standard.

There is a LUNKENHEIMER Distributor in every commercial center ready to give prompt service. Specify LUNKENHEIMER Iron Body Valves and insist on getting what you specify.

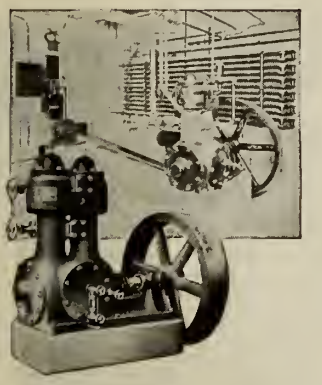
A YORK MACHINE

does not require a skilled operator



DON'T get the impression that Mechanical Refrigeration means complicated apparatus, difficult to understand and costly to operate. You need have no such fears if it's a YORK installation.

A York plant is the embodiment of simple efficiency. No skilled attendant is required. One of our customers says in testifying to the simplicity of his York plant, "It is being operated successfully by an employee who, prior to the installation of the machine, had never seen one nor had any experience in operating one."

Constant attention is unnecessary. The simple regulation of one valve gives any degree of cold you want—freezing, zero, below zero—whatever your business needs may require.

If you want the simplest, most efficient, most economical refrigerating system, you will investigate the York Refrigerating Plant.

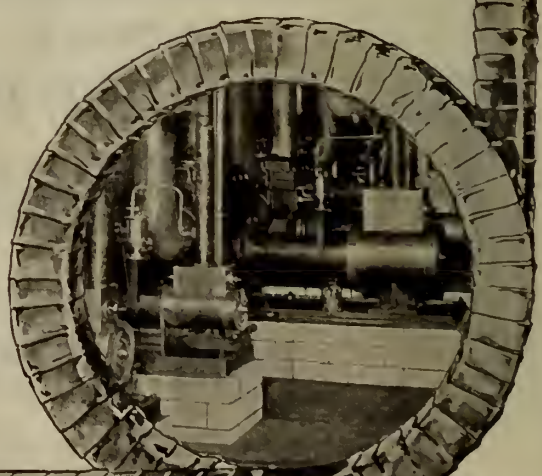
John Crane

Eight Years of Packing Service
JOHN CRANE Flexible Metallic Packing Shows Greatest Results in Constant Service

Eight years ago Chief Engineer, N. Gross, of the Standard Oil Building, Chicago, installed JOHN CRANE Flexible Metallic Packing in the boiler-feed pump pictured below. Mr. Gross reports packing and pump in good order after eight years and has standardized JOHN CRANE on all service.
JOHN CRANE holds this long service record because of its scientific, practical construction. Made of babbitt foil and graphite, it brings Packing science "The Babbitt-bearing Principle," and while responding to the slightest pressure of the gland never dries out, but remains compressible and will not score rods.



Write for your copy of "THE ANSWER" a book that tells unusually interesting things about packing problems

$50 Worth of Books for $3

Fifteen of the Best Sellers of the Year For $3 if you subscribe to MacLean's Magazine

During 1921 MACLEAN'S, Canada's National Magazine, has published the whole or major portion of the following fifteen books, which have since been published in book form—or are shortly to be published:

(1) Reminiscences of a Raconteur
—Col. George H. Ham
The recollections of Canada's premier story teller, the C.P.R.'s knight of wit and wisdom, who has known every person worth knowing in Canada during the past half century.

(2) Masques of Ottawa—"Domino"
A series of brilliant, biographical sketches of Canadians prominent in politics and business; analogous to "The Mirrors of Downing Street."

(3) Canada at the Cross-Roads
—Agnes C. Laut
A series of vigorous, inspirational articles showing how Canada is standing on the threshold of nationhood; constructive criticism indicating how full national status is being achieved.

(4) Policing the Plains
—Rev. R. G. MacBeth
The latest and most authoritative history of the Royal North West Mounted Police, by a padre who himself took part in the Riel Rebellion and has associated with many of the leading characters in Canada's famous frontier force.

(5) The Drama of Our Great Forests
—Arthur Heming
The pulsating, throbbing, human-interest story of Canada's great northern fastnesses, told by the man who will go five hundred miles to get a fact; authentic, enthralling.

(6) The City of Peril—Arthur Stringer
An up-to-date narrative of a Bolshevistic plot which was nipped in the bud by an adventurous young millionaire; including a delightful Stringer-like romance.

(7) Pawned—Frank Packard
A fast-moving story of a triple regeneration, shifting wth kaleidoscopic speed from the South Sea Islands to this continent—novel, intense, gripping, mystifying.

(8) The Valley of Gold—David Howarth
The first novel from the pen of an athletic Methodist parson now resident in Miami, Manitoba—a true-to-life account of the Qu'Appelle Valley of Saskatchewan as it was twenty years ago; vigorously, thoroughly Canadian.

(9) Mostly Sally
—Pelham Grenville Wodehouse
A worthy successor to "The Little Warrior," told in the inimitably facetious and whimsical vein of this English master-craftsman.

(10) The Yellow Streak
—Valentine Williams
The story of a murder mystery solved by real human beings; from the pen of the author who wrote "The Man With the Club Foot."

(11) The Gates of Tien T'ze
—Leslie Howard Gordon
An enthralling book which ran in MACLEAN'S as a five-part serial; dealing with life in London when Anglo-Saxons and Chinese met at cross purposes.

(12) Lenix Ballister, Diplomat
—Archie McKishnie
A dozen short stories about the typical Canadian negro of Western Ontario; a forthcoming volume from the pen of one of Canada's foremost fiction writers.

(13) Prince Renine—Maurice Le Blanc
Eight more stories in which the leading character is the thinly disguised Arsene Lupin, one of the world's famous characters in detective fiction.

(14) A Series of Short Stories
—"Sapper"—H. C. McNeile
Ten or a dozen brilliantly written stories, impregnated with human interest, from the pen of one of the most successful English authors brought to the fore during the war.

(15) The Man Who Knew Too Much
—G. K. Chesterton
A collection of eight stories, each with its distinctive mystery, and containing the usual Chestertonian twist, from the pen of the man who wrote the "Father Brown" series.

Readers of MACLEAN'S got all these books in 1921—ten books of fiction and five of a more serious character, biographical, reminiscent, political—permanent literature.

In addition, they got a most attractive offering of the best short stories and the twice-a-month Review of Reviews department, which kept them posted on current topics and developments in all parts of the world, as well as the multitude of Special Articles on Topics of National Interest in Canada, which have made MACLEAN'S something more than a magazine—a National Institution.

MACLEAN'S readers got all this immense value in 1921—in 1922 they will get bigger value still. And you get all this for $3.00—the price of a year's subscription—24 twice-a-month issues of

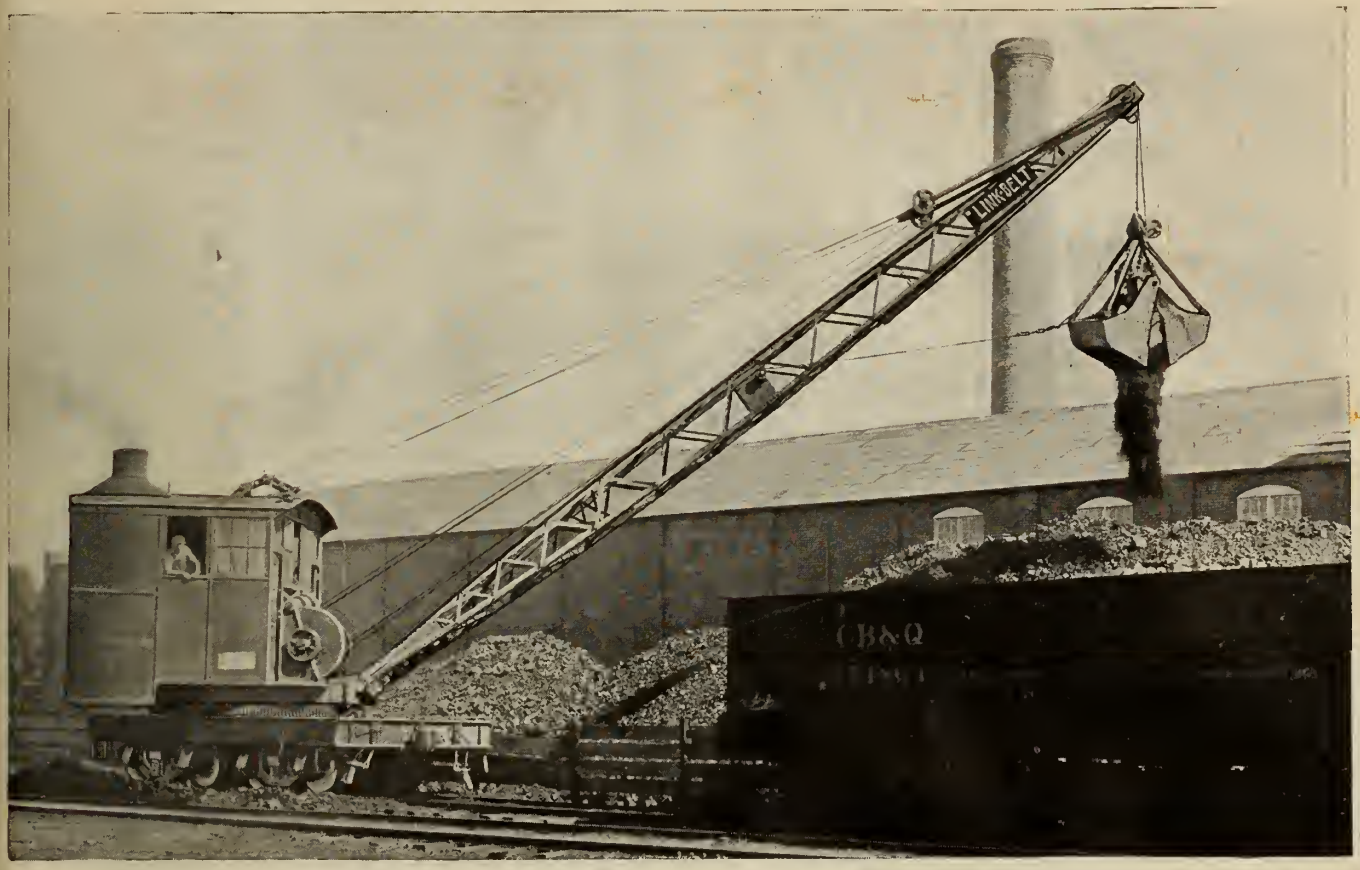
LEONARD



Cutting Handling Costs 66⅔%

"We got our first Link-Belt Crane in January, 1919. It was purchased primarily to unload coal, but it immediately proved so handy that we have been using it on all kinds of odd jobs about the plant," says Mr. A. Gillis, Chief Eng., Owosso Sugar Co., Lansing, Mich.

"When our plant is operating 24 hours a day, we consume from 125 to 130 tons of coal a day. Coal is shipped to us in 50-ton cars, and unloaded into our storage bins by crane. The Link-Belt crane with a 1½ yard bucket, easily unloads from 10 to 12 cars, aggregating over 500 tons, a day.

"Our plant is busy making sugar from October to the first of January. During this period the beets are shipped to us by freight as fast as we can take care of them. We used to unload them by hand, but are now doing this work entirely by crane. During the shipping season we unload from 500 to 800 tons of beets per day.

"At the 1916 labor rates it would cost us $75 to unload 500 tons of coal by hand, and $44 to unload 400 tons of beets. The Link-Belt crane will handle the coal for $25, the beets for $16. This is a saving of $78 in wages in one day, or $468 in one busy week, over the cost of labor four years ago.

"Our first Link-Belt Crane proved such a useful machine that a few months later we bought another. They have already paid for themselves in wages saved."

Are you using obsolete methods in handling your materials? Let our engineers look over your conditions. Send for catalog.

JONES

The Principle Is Right

Jones Originated Under-Feed Stoking

Under-feed stoking dominates in the power plant world by sheer force of merit—that is the indisputable proof that the under-feed principle—a *Jones* principle, by the way—is *right.*

In 1888 E. W. Jones, a Canadian, invented and operated the forefather of all under-feed stokers. His first wood-burning under-feed stoker proved the feasibility of introducing air at the point where the volatile gases in the fuel are driven off by the heat above.

This basic principle has not been changed—it was, and is, *right.* The method of applying it has been brought to the highest stage of perfection yet attained in the modern Jones stoker.

Distinctive Features Mean Correct Application . .

THE Jones Stoker makes the basic under-feed principle of greatest practical value in meeting the super-requirements of modern high-duty stoker firing.

Jones retorts are longer and deeper, so that even at high combustion rates the travel of the fuel bed is comparatively slow. This insures complete distillation of volatiles and complete coking of the coal before it reaches the combustion zone—two essentials in securing the full value of the Jones under-feed principle.

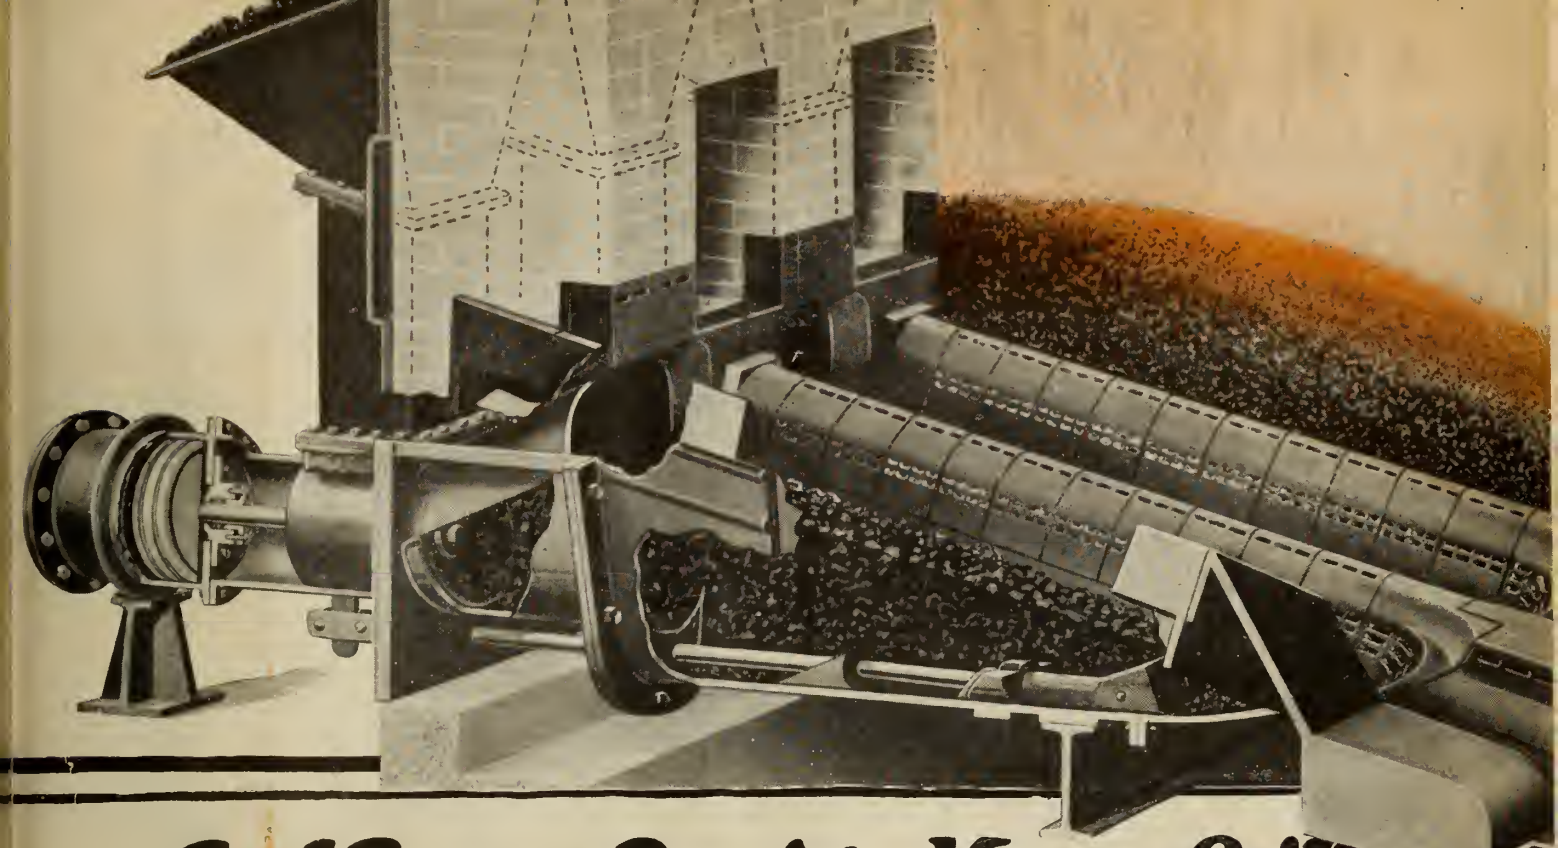
By automatically controlling the air and fuel supply, so the ratio of air to fuel is correct for the combustion rate necessary to meet a given steam demand, highest combustion efficiency is assured.

The individual control of retorts—an exclusive feature—is a provision against holes in the fire and uneven burning—a condition difficult to overcome in other types of under-feed stokers.

Avalanching or sliding of unburned fuel onto the dump plate is next to impossible for the slope of the retorts is only 11 degrees. The movement of the fuel bed of the Jones is a mechanical, not a gravity, movement.

Smokeless operation is assured by complete combustion.

"Pays for Itself— Then Pays Dividends"



"And Better Design Means Still Better Under-Feed Stoking"

A GLANCE at the sectional view above of the Jones "A-C" in operation reveals its unapproached simplicity *from coal-feed to ash-discharge.* This means low cost stoker service—lower maintenance, less repairs, less operating labor

Note that there is only one moving unit to each retort—the piston, ram and pusher rod. The pusher rod is the only moving part within the furnace and it is buried deep in the green fuel. ***There are no moving parts in the fire.*** Since each retort is a separate, self-contained unit, and, consequently, there is no need for fine alignment, installation expense is minimized. All gears, levers, gear shifts, crank shafts, chain drives, sprockets, shearing pins and clutches are eliminated.

The counterbalanced dump plate in the "A-C" type, easily operated by one man, is another common sense feature. It does away with complicated, high maintenance, power driven dumps.

The reasons for Jones leadership are covered in detail by a newly-printed, highly informative booklet "Ten Points of Jones Superiority." Progressive engineers should request a copy.

Jones stokers are made in three types covering all plant requirements: the "A-C" (Automatic-Cleaning) type for highest duty requirements; the direct cleaned "Standard" stoker, and the "Standard" Side-Dump (self-cleaning) stoker.

How to Make Use of Logarithm Tables

This Is the Third and Last Article on This Subject, and a Number of Calculations Are Worked Out Which Cover Most of the Typical Cases Which Occur in Practice

By T. H. FENNER

A Correction

OWING to typographical errors in the preceding article, it is necessary to make some corrections before going further with the work.

In the first column, first page of the article in the issue of Dec. 5, speaking of characteristics, the ciphers were omitted before the number .415. Thus the text should read: "the characteristic of the log of .415, is $\bar{1}$, that of .0415 is $\bar{2}$, and that of .00415 is $\bar{3}$ and so on." The actual text left out the ciphers, making the three different cases all read .415, which was quite obviously an error.

In the last part of the article, the minus characteristics also got twisted. The revised version is given herewith.

Suppose we have to raise a decimal quantity to a higher power or to find the root of a decimal quantity. Let us take first of all the raising to the 2nd power of a decimal quantity, or getting the square of a decimal quantity, say, .45. Now the log. of .45 is $\bar{1}.633213$ that is the characteristic is a minus quantity. Now how are we to multiply a log. containing a minus characteristic and a positive mantissa? There are several ways of doing this.

Let us take the easiest method first, which is to multiply the mantissa first, and then multiply the characteristic, and then add the two together. Thus we should have .653213 x 2=1.306426, and to this must be added the product of $\bar{1}$ x 2 which is of course $\bar{2}$.

Then we have $\begin{array}{r} 1.306426 \\ \bar{2}. \\ \hline \bar{1}.306426 \end{array}$

The anti-log of this is 2025 and as we have a minus characteristic the square of .45 will be .2025.

A second method is to add a positive number to the negative characteristic, and multiply in the ordinary way. After that is performed, the product of the added positive number and the multiplier is subtracted from the log. already found.

Using our same figures again for illustrative purposes, we have log. of .45 is $\bar{1}.653213$. If we add 10 to the negative characteristic we shall have a positive characteristic 9. That is 10 plus $\bar{1}$ is 9. The log. would then be 9.653213 and this multiplied by 2 is 19.306426.

As we have added 10 we must now compensate for that by subtracting the product of $\overline{10}$ and 2 which is $\overline{20}$ and the log. will be

$$\begin{array}{r} 19.306426 \\ \overline{20}.0000000 \\ \hline \bar{1}.3064260 \end{array}$$

which is we see the same as before.

The Napierian Log

Before giving more examples, we must pause for a moment to notice a system of logs, known as "hyperbolic" or Napier's logs. This system has a base of 2.718282, but is used only in the calculation of abstract mathematical formulae. When it is necessary to make use of this system in the ordinary processes of engineering work, there exists a simple method of converting ordinary logs into Napierian logs, and vice versa. All that is necessary is to multiply the common log by 2.3026, and conversely, the Napierian log can be converted by dividing the common log in the same way. However, it is only in rare cases that this is needed.

The "hyperbolic" or "Napierian" or "natural" logarithm, it being known by all these names, is usually denoted by the symbol e. Thus when we see a formula which contains the expression log e followed by a number, we know that what is required is the Napierian logarithm of the number denoted. Thus in the formula

$$P = P^1 - \frac{1 + \log e\, R}{R}$$

we understand that the product of the common log of R and 2.302 must be added to 1 for the numerator of the fraction. For instance if R=2. Then log e R will be

$$\log 2 \times 2.302$$
$$= .3010300 \times 2.302$$
$$= .6929$$

and log e R=.693

Some Examples of Work

We are now in a position to give examples covering the use of logarithms in a variety of different applications.

Let us take first a formula which is more or less familiar to all stationary engineers, the well known expression for I.H.P. That is

$$\text{H. P.} = \frac{P \times L \times A \times N}{33000}$$

where P=Pressure per square inch

L=Length of stroke in feet

A=Area of piston in sq. inches

N=Number of strokes per minute

Assume numerical values for these, say: P=75, L=2.5, A=16x16x.7854 and N=120 and solve the expression by means of logarithms.

We have

$$\text{H.P.} = \frac{75 \times 2.5 \times 16 \times 16 \times .7854 \times 120}{33000}$$

$$\begin{array}{rl} \log & 75 = 1.8750613 \\ \text{“} & 2.5 = .3979400 \\ \text{“} & 16 = 1.2041200 \\ \text{“} & 16 = 1.2041200 \\ \text{“} & .7854 = \bar{1}.8950909 \\ \text{“} & 120 = 2.0791812 \\ & \hline & 6.6555134 \\ -\log & 33000 = 4.5185139 \\ \hline \log \text{ of H.P.} & = 2.1369995 \end{array}$$

The nearest log in the tables is .1369741 and the anti-log is 13708. As the characteristic is 2 the anti-log or the num-

ber required is 137.08. If we want to get the exact figure we can take the proportional parts by the method already shown, but it is hardly worth while in a calculation of this kind.

The horsepower or the fuel consumption of a vessel varies as the cube of the speed. If the speed is increased to 20 knots from 10, and the consumption at 10 knots is 2 tons per hour, what is the new consumption?

$$10^3 : 20^3 :: 2 : \chi$$

$$\chi = \frac{20^3 \times 2}{10^3}$$

$$\log 20 \times 3 + \log 2 - \log 10 \times 3 = \chi$$

$3 \times \log 20 = 1.3010300 \times 3 = 3.9030900$	
$\log 2 =$	.3010300
	4.2041200
$3 \times \log 10 = 1.000000$	$= 3.000000$
$\log \chi =$	1.2041200

The anti-log of 1.2041200 is 16, and the characteristic being 1 the number is 16, which is the answer.

As an example of raising numbers to different powers, and extracting roots, take the following:

$$\sqrt[4]{\frac{17^3 \times 1.365^2}{1.5^5}}$$

That is 17 cubed $\times$1.365 squared, divided by 1.5 raised to the fifth power, and the fourth root of the quotient extracted. This would be a long process by arithmetic in the ordinary way, and pregnant with possibilities of error. By logs it is simple. It is stated in the following way

$$\frac{\log 17 \times 3 + \log 1.365 \times 2 - \log 1.5 \times 5}{4}$$

Then $\log 17 \times 3 =$	1.2304489 × 3 = 3.0913467
$\log 1.365 \times 2 =$	.1351327 × 2 = .270.2654
$\log 1.5 \times 5 =$	.1760913 × 5 = .8804565

3.6913467)
.2702654) add

3.9616121)
.8804565) subtract

4)3.0811566
.7702891

anti-log of .7702891 is 5.8924

Take the formula

$$(PV)^{1.406} = (P_1V_1)^{1.406}$$

$$P^{1.406} = \left(\frac{P_1V_1^{1.406}}{V}\right)$$

$$P = P_1 \left(\frac{V_1}{V}\right)^{1.406}$$

substituting values

$$P = 50 \left(\frac{1}{2}\right)^{1.406}$$

$$\log P = \log 50 + (\log 3 - \log 2) \times 1.406$$

$$= 1.6989700 + (.4771213 - .3010300) \times 1.406$$

$$= 1.6989700 + .2475843$$

$$= 1.9465543$$

$$P = 88.421$$

Take a case in which we have to divide a whole number by a decimal. That is where we have to subtract a log with a negative characteristic from one with a positive characteristic. For instance the area of a piston is 100 sq. inches and we want its diameter.

$$D = \sqrt{\frac{100}{7854}}$$

and $\frac{\log 100 - \log .7854}{2} = \log D$

2.0000000
$\bar{1}.8950909$

2)2.1049091

1.0524545 = log D

and D = 11.284

When subtracting a negative characteristic we proceed as if performing addition. Thus in the mantissa when we subtract the final figure before the decimal point we have 9 from 0, and we add a unit which must be carried over to the characteristic, and say 9 from 10 leaves 1. Adding this 1 to the $\bar{1}$ in the characteristic we have $\bar{1}+1=0$, and the addition is $2+0=2$

The system is based on the algebraic rule of addition and subtraction. In subtracting algebraic quantities we change the sign and add. Thus suppose we wish to subtract+4 from+6. We change the sign of 4 from+to—and add, thus

$$+6-4=+2$$

If we wish to subtract—4 from+6 we have

$$+6+4=+10$$

To subtract—4 from—6 we have

$$-6+4=-2$$

Now take two logs with negative characteristics, which have to be subtracted. Let us suppose a division sum

.7854
.07854

We have log .7854—log .07854
which is $\bar{1}.8950909 - \bar{2}.8950909$

$\bar{1}.8950909$
$\bar{2}.8950909$
1.0000000

That is changing the sign of the lower quantity we say $+2+\bar{1}=1$, and the answer is 10, because .000000 is the log of 1, and the characteristic being 1, we must have two figures, therefore we add a cipher to the 1, and 10 is the number.

Another example: divide 3.1416 by .7854

log 3.1416 = .4971509
log .7854 = $\bar{1}.8950909$
.6020600

Here again we carry 1 over and adding it to minus 1 we have 0. The log then is .6020600 and the anti-log is 4.

As an example of dividing logs with negative characteristics, take the following. Find the square root of .005.

We have $\frac{\log .005}{2}$

$\text{Log } .005 \quad \bar{3}.6989700$
$\frac{}{2} = \frac{}{2}$

$\bar{3}$ is not divisible by 2. However if we add $\bar{1}$ to it we shall have $\bar{4}$, which is divisible by 2. In order to balance this we must add+1 to the mantissa and we then have

2)$\bar{4}$+1.6989700
$\bar{2}.849485$

and the anti-log is 70710, and as the characteristic is $\bar{2}$, we have .070710. Suppose we multiply this by ordinary methods to see how near we are

.07071
.07071
07071
49497
49497
.0049999041

which is close enough for all practical purposes, the error being .0000001.

In adding —1 to the characteristic and +1 to the mantissa in order to get an equal divisor we have not altered anything, because we have simply said

$$\bar{3} + \bar{1} + 1$$

which gives $\bar{4}+1=\bar{3}$ which is where we started.

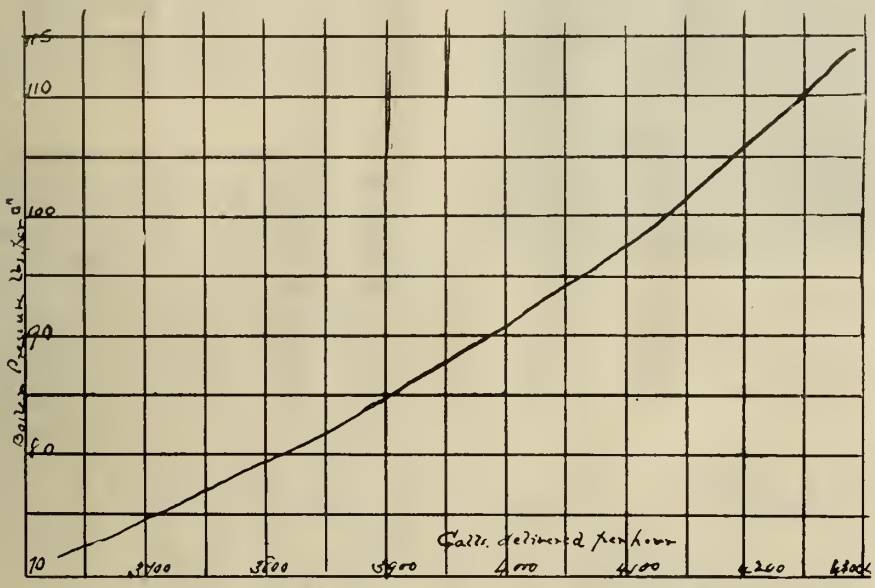
(Continued on page 25)

Results of Tests Made On An Injector

Every Power Plant Engineer, and a Good Many Marine Men Are Interested in Injectors. Here Are Some Facts and Figures Which Clear Up Some of the Dark Points.

By A. WOODBURN

IN view of the large number of injectors which are in use in power plants of medium size, and the interest taken in this type of apparatus by power plant engineers, the following test carried out under the supervision of Professor Angus of Toronto University should prove of value. We are indebted to the James Morrison Brass Manufacturing Co. whose double tube injector was the instrument tested, for the privilege of publishing the particulars of this test.

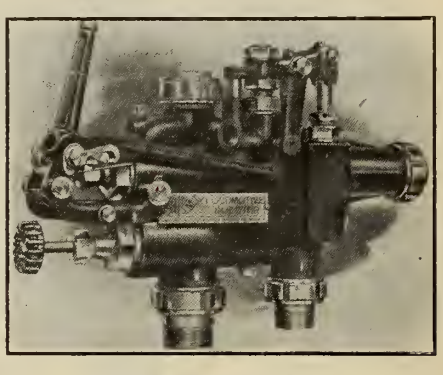


Discharge curve constant suction pressure and varying discharge.

There are a large number of power plant engineers using the injector for feeding their boilers, who no doubt often wonder just what is the condition regarding steam consumption in relation to the amount of water fed to the boiler. The figures obtained in the accompanying test are very illuminating in this respect, and also furnish very good evidence of the efficiency of the injector considered from a thermal standpoint. The injector used was of the type known as the "Morrison" locomotive injector, and is illustrated both in section and by an outside view herewith. In this type of injector the operation is in two stages, one of which consists of lifting the water from the source of supply and delivering it to a chamber from where it is taken and delivered to the boiler by the second stage. The accompanying illustration in section and list of parts shows the construction very plainly.

Experience with locomotive work, has, it is said, demonstrated the fact that the double tube injector is the most satisfactory design for the conditions obtaining in the high pressure locomotive in use today. With this type of injector feed water at a temperature of 100 degrees F. can be handled when the steam pressure does not exceed 150 lbs per sq. inch, and at 90 degrees F. where the steam pressure is from 200 to 250 lbs per sq. inch.

Owing to the liability to erosion due to the high velocity of the steam and water passing through the tubes, a metal of very high resistance is required, and the metal used in the construction of these tubes is of a special quality of hardness, which has been evolved by experiment and research. Great accuracy is also required in the bore of the nozzles, the variation in diameter being within a toleration limit of 1-10,000th inch. The range of working pressures in the type of injector under test, is from 30 lbs per square inch to 300 lbs per square inch. This is made possible by the double tube construction, the regulating valve on the lifter tube being capable of adjustment to any variation.



Outside view of injector.

The apparatus used in making the test is illustrated in the sketch. The suction of the

injector was arranged to draw from the tank A, and the discharge was led to the tank B. The different connections are plainly marked, and the arrangement can be clearly understood from the sketch. The discharge curves shown are obtained, first with the suction head constant, and the steam pressure varying, and second, with the suction head changing and the steam pressure constant. The third curve shown, shows the ratio of steam used to the lbs of water delivered. In the report of the test the quantities determined are tabulated, the table being given herewith. Following is Professor Angus's report, and the figures obtained.

Description of Test

Test performed on a Morrison Type A.I. Locomotive injector to determine the effects of varying steam pressures and varying suction pressures and to determine the discharge per hr. in gallon per lb of steam used.

Arrangement of Apparatus

The injector was set up to draw water from one accurately calibrated tank marked A and discharge the water into another marked B. Gate valves were placed in both the suction and discharge pipes to regulate the suction and discharge pressures which were measured by a mercury manometer and calibrated pressure gauge, situated between the valves and the injector. Steam was supplied by two Babcock and Willcox boilers giving 150 boiler Horse Power. The steam pressure was controlled by an ordinary globe valve situated near the injector. the pressure being indicated by a tested calibrated steam pressure gauge placed between the control valve and injector. The percentage of moisture in the steam entering the injector was measured by a Peabody's throttling calorimeter connected between the control valve and the injector.

Method of Conducting Tests

The injector was set in operation and when the various valves had been regulated to give the desired pressures instantaneous readings were taken on both suction and discharge tanks. The pressures were maintained at the desired valves for a period of fifteen minutes at the end of which time the injector was instantly stopped and readings again taken on the tanks.

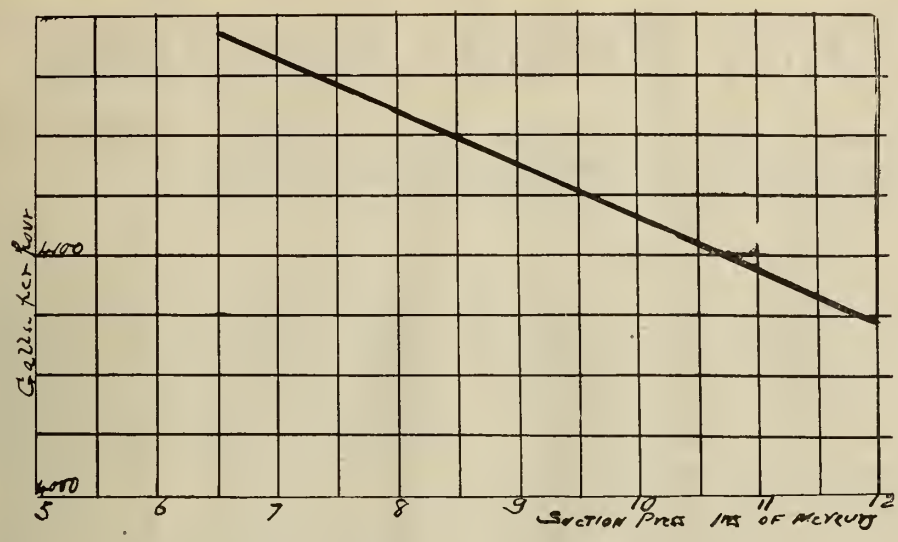
Calculation of Results

From the readings taken on the tanks the weight of water drawn from suction tank and the weight discharged into discharge tank were computed, the difference between the weight discharged and the weight of water drawn from the suction tank giving the weight of steam used.

To determine the discharge per lb. of steam the total weight of water discharged into the discharge tank for a fifteen minute period was divided by the total weight of steam used per fifteen minute period.

The gallons discharged per hr. was computed by multiplying the weight of water discharged in fifteen minutes by four and dividing by ten (the weight of 1 gallon (imperial) of water).

The heat balance was computed by determining the total heat in the steam correct-

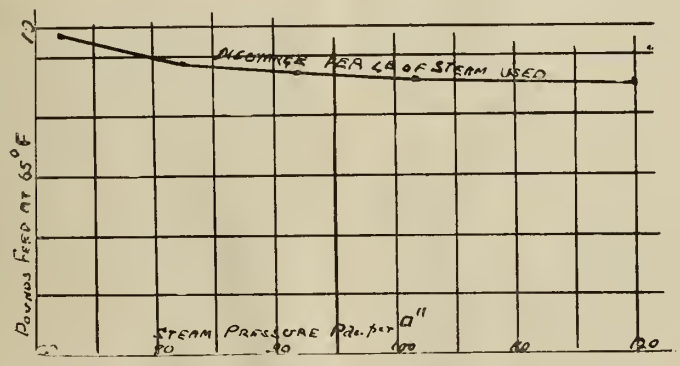


Discharge curve, constant pressure and varying suction pressure.

ing for the quality as found by calorimeter and subtracted from this the heat returned to the boiler in heated feed water, calculated from the weight and rise in temp. of the feed water, and also subtracting the heat energy used in pump work calculated from the pressure differences between the suction and delivery lines times the weight of water discharged. The net result gave the radiation loss.

A discharge curve with varying steam pressure at constant suction pressure and a discharge pressure slightly higher than the steam pressure shows an accelerating decrease in discharge per hour for increasing steam pressures.

A discharge curve with constant steam and discharge pressures and varying suction pressure shows a regular and constant decrease in discharge for a regular increase in suction pressures.



Ratio of steam to water raised.

HOW TO MAKE USE OF LOGARITHM TABLES

(Continued from page 22)

Take one more example. Find the 5th root of .636

We have $\frac{\log .636}{5} = \frac{1.803457}{5}$

5 will not divide into $\bar{1}$ but by adding $\bar{4}$ to $\bar{1}$ we get $\bar{5}$. Then we must add $+4$ to balance it and we have

$$\frac{\bar{5}+4.803457}{5} = \bar{1}.960691$$

and the number is .91346.

Multiplication of negative quantities may be performed in a somewhat similar way—as explained previously. If the multiplier is a single figure, the operation can be performed direct. For instance take the above case, and multiply $\bar{1}.960691$ by 5

$$\begin{array}{r} \bar{1}.960691 \\ \times\ 5 \\ \hline \bar{1}.803455 \end{array}$$

As we have to carry over a positive 4 from the Mantissa, we must add this to the product of the characteristic. Thus we get $\bar{1}\times 5=\bar{5}$ and adding the 4 from the carriage we have $\bar{5}+4=\bar{1}$.

When the multiplier consists of more than one figure, the Mantissa can be multiplied separately, and the product of the multiplier and negative characteristic added after. Take

$\bar{9}.3010300\times 25$

$$\begin{array}{r} 3010300 \\ 25 \\ \hline 15051500 \\ 6020600 \\ \hline 7.5257500 \end{array}$$

add $\bar{9}\times 25=\bar{225}.0000000$

$$\bar{218}.5257500$$

Take the same problem another way. Add $\times 10$ to the minus 9 making the characteristic $+1$. Then multiply

$$\begin{array}{r} 1.3010300 \\ 25 \\ \hline 6.5051500 \\ 26.020600 \\ \hline 32.5257500 \end{array}$$

Then add $-10\times 25=-250$

$$\begin{array}{r} 32.5257500 \\ -250. \\ \hline 218.5257500 \end{array}$$

Take a more reasonable example:

$$\begin{array}{r} \bar{1}.3010300 \\ 12 \\ \hline \bar{9}.6123600 \end{array}$$

By the other method add $+2$

Then

$$\begin{array}{r} 1.3010300 \\ 12 \\ \hline 15.6123600 \end{array}$$

add $-2\times 12=\bar{24}.0000000$

$$\bar{9}.6123600$$

The author hopes these three little articles will serve to dispel the feeling of awe with which a good many men look on this subject, and start them delving for themselves.

In the report of Mr. E. L. Cousins, Department of Industry, submitted to the Board of Control of Toronto this past week, the definite opinion is expressed that normal times are already here. Mr. Cousins stated that the representatives of 17 United States industries have recently investigated manufacturing possibilities in Toronto, and, in the adjustment of the department, there are excellent chances of a number of new branches being opened shortly.

The Canada Paper Co., Windsor Mills, Quebec, have just put into operation a new boiler plant in connection with their St. Francis mill and it contains three 250 h.p. water tube boilers and has room for a fourth.

For Better Boiler Room Operation

This Is the First Section of a Paper Read Before the Stoker Manufacturers' Association—It Shows in a Most Interesting Way the Relation of the Different Items to Cost of Steam

By C. W. DeFOREST

THE boiler room is only one of the links in the chain of operations involved in transforming the energy stored in our coal resources into the electrical energy furnished to consumer. During the recent past, the attention of engineers has been frequently called to the fact that the efficiency of modern boiler room practice is very much higher than the efficiency of producing and mining coal, and of converting the energy of the steam into electrical energy. It might seem, therefore, that attention should be concentrated particularly upon those links in the chain of operations involved in transforming the latent energy of coal into electrical energy available to consumers, where the greatest returns can be obtained from a given expenditure. But while this is true, and is becoming more and more apparent, it can be shown that the possible increase in efficiency in many of our boiler plants, more than justifies the necessary expenditure involved.

In order to follow the title of the subject assigned for this paper, let us first consider the necessity for better boiler room operation. We can do this by briefly reviewing the principal factors which go to make up the cost of producing electrical energy from the coal pile at the generating station to the bus bars.

The three principal factors entering into the cost of production are:

(1)—Investment cost;
(2)—Cost of fuel;
(3)—Organization, personnel, supplies and maintenance costs.

To simplify our problem, we may leave the first factor out of consideration, and assume that the plant and equipment are properly designed and installed.

Let us suppose that we have a modern station, of about 100,000 k.w. capacity, consisting of turbo units of from 20,000 to 35,000 k.w. each, and a boiler plant equipped with boilers each of 1000 rated h.p., or larger, operating at steam pressures of 250 to 300 pounds, and a total steam temperature of from 600 deg. to 700 deg. F. Such a plant, with good load factor, should have a station water rate of 12 pounds per k.w.h. What are the factors which determine the unit cost of energy? The following table, No. 1, shows how the various factors involved enter into the total cost.

Table No. 1

Superintendence, Clerical & Efficiency Dept	2.00
Boiler room operation, inc. ash disposal	5.12
Boiler room repairs	3.80
Engine room operation, inc. electrical	4.60
Engine room repairs	3.07
Miscellaneous expense	4.61
Coal at $4.00 per ton	76.8
Coal at $5.00 per ton	80.5
Coal at $6.00 per ton	83.2

From Table No. 1, we see that the fuel cost at $4.00 per ton is 76.8 per cent of the total; at $5.00 per ton, 80.5 per cent; at $6.00 per ton, 83.2 per cent. These figures are for a plant capacity factor of 41.2 percent. As this factor is increased, the percentage of cost per k.w.h., due to fuel will increase. These figures should bring out clearly the necessity for continued effort to secure better boiler room operation. Where the cost of producing a k.w.h. is higher, the necessity for saving will be more apparent.

Of course, there are three distinct elements which determine the coal per k.w.h. This first transfers the energy of the coal into steam, the second transfers the energy stored in the steam into mechanical energy at the turbine shaft, and the third changes the mechanical energy at the turbine shaft into electrical energy at the generator terminals.

Given turbines and generators of definite characteristics, it is comparatively easy to watch operations and to make the necessary adjustments to maintain satisfactory operating conditions. But the first factor, that of producing the steam, which represents from 76.8 per cent to 83 or 85 per cent of the total cost, is carried out under conditions that are constantly changing. The losses taking place are doing so minute by minute and like "Water through the mill," once lost, cannot be recovered.

The art of fuel burning has made great advances in practice, in the past ten years power station management is recognizing the necessity of equipping the boiler plant with suitable instruments to enable the Combustion Engineer to know what is taking place in the furnace and throughout the heat-transfer equipment. But the mere installation of instruments does not result in the saving of a single pound of fuel.

Let us review the factors entering into the cost of "Boiler Room Operation." Table No 2 shows a typical "Set up" of the gross cost of boiler operation

Table No. 2	Cost per month
Stoker engineers and firemen	$1,980 00
Water tenders	420.00
Heater tenders	378.00
Economizer tenders	624.00
Oiler	120.00
Instrument attendant	240.00
Relief men	284.00
Blowing soot, boring tubes, inspection, cleaning boiler room and apparatus	1,600.00
Proportion of time of assistant to superintendent and chief engineer	150.00
Total cost Boiler Room Operation	$5,796.00

The above table shows that the cost of Stoker Engineers or Firemen, including the time of the Assistant Superintendent, actually given to boiler room operation, is only $2,130.00 per month, or 1.55 per cent of the total cost of power house operation, and including the total cost of Superintendence, Clerical Work and Efficiency Engineer, charging all of the cost to the boiler room, is only 3.25 per cent of the total cost of power house operation.

Five per cent variation in furnace and boiler efficiency represents quite a sum per year; with coal at $5.00 per ton; it amounts to $70,000.00; even two per cent amounts to $28,000.00.

The only way to gain that last two to five per cent in boiler efficiency, is by constant, efficient watchfulness on the part of the stoker engineers, boiler room foreman, and the efficiency engineer, and we cannot afford to employ cheap, inferior men in the boiler room.

In order to get results, we must have the real genuine co-operation of the men. They must be personally interested in their work and the results of their work, and to obtain this end, the conditions under which they work must be pleasant, their wage must be adequate, and they should be kept in touch with the results of their work.

Our Company does not hire experienced firemen. We try to select clean, bright men, with brains, regardless of former experience in the boiler room. In fact, we frequently find, the less experience they have had, the less we will have to overcome. Upon employing a man, he is put in as boiler room helper, then economizer tender, heater tender, boiler maintenance work, and finally on stoker operation or firing.

We conduct two classes a week, at different hours, which it is compulsory to attend. The men are taught the principles of Combustion Engineering and Elementary Mechanical Engineering, as especially applied to the equipment in our station.

The instrument equipment enables us to have a full knowledge of draft conditions and temperatures throughout the furnace, boiler and economizer, steam flow on indicating and integrating meters, pounds and quality of coal used by each boiler and by sampling and analysis, the amount of combustible in the ash. All instruments are carefully maintained and the records carefully compiled daily. After these records are obtained, they are carefully analyzed, and every effort is made to apply the information thus recorded, to maintain our highest standard of performance and, if possible, improve it.

Each day we know the efficiency obtained by each boiler and the general performance of each pass and part of the boiler, from the furnace on up through the economizer. This information is compiled in useful shape daily and checked by the Efficiency Engineer and the Superintendent of Production, and readily shows any furnace, boiler or

economizer that is falling off in efficiency, as well as the reason for this condition.

If we expect to keep a boiler plant up to an average efficiency of from 75 to 80 per cent the boiler plant as a whole must be well maintained. How often we find that equipment will give high economy when new, but that the efficiency drops off after a year's use. It is needless to go over the long list of conditions in a boiler plant that must be looked after. But manufacturers know from long experience, that apparatus will usually meet your guarantees when new and tested by your own engineers, only to fall off when left to the care of the station operators. From this it is apparent that lack of proper maintenance inevitably involves inefficient operation, and that the fault generally lies with the operating force, or the management.

The modern power house, with its multiplicity of auxiliary apparatus, and being worked at increasingly higher stresses, cannot be left to haphazard inspection and maintenance. It is beyond the realm of possibility to expect any engineer or foreman, however conscientious he may be, to remember, in detail, when different apparatus was inspected or repaired. Record filing systems have been devised for performing this function, and it has been demonstrated that they are less liable to error than the most conscientious employee. It is not sufficient that a record be kept of when repair work was performed. A system must be used to insure the regular periodic inspection and maintenance of every piece of equipment.

The scheme we have adopted is to have a card for every boiler, stoker, economizer, motor, pump, all principal valves, switches, cables and every other separate piece of equipment. These cards show the principal data for the equipment as number, capacity, etc., the period of inspection, whether one week, one month or two months.

They are kept in a file, arranged according to date and distributed so that a certain number of cards are handled each day. One man is responsible for the proper handling of the cards and work orders. Each day, the cards covering the apparatus to be inspected or repaired, are taken out and a specific work order issued for each piece of equipment, a perforated stub, bearing the same number as the work order, is retained by the maintenance clerk. The work orders are then given to the Chief Engineer for distribution to the proper foreman and repairmen. After the inspection, or repair, is completed, the work orders are filled out showing the work done, amount of time spent on the work, etc., and returned to the Chief Engineer, who personally inspects the work to see that it has been done according to the order. The completed work orders are then returned to the maintenance clerk, and verified with the stubs. By this arrangement, the Chief Engineer, and his assistants can use their time most effectively—no filing system can perform this function.

This system has enabled us to keep our equipment in good condition.

You will find a great many engineers, who are good men to have when trouble comes and who will work day and night to keep things going, but the man that will save you money, is the one who will forestall trouble, and the surest way is by regular and consistent inspection and repair.

Relation of Stokers to Power House Economy

The real "heart" of the power station lies in the stoker, furnace and boiler. I think they are the one most important factor in the station, certainly from an economic point of view. The stoker handles 80 per cent of the entire cost of power generation, and we cannot give it too much attention.

The three vital considerations in the design and operation of a stoker are :

1. The feeding of coal into the furnace.
2. The air distribution to the fuel bed.
3. The disposal of the ashes.

The general principles of these three operations are determined by the design of the stoker and are settled when the stokers are purchased and installed. Of course, there are innumerable details of design and construction that affect the efficiency and successful operation of the stokers.

Modern stokers are expected to burn coal at high combustion rates, which means that the parts immediately under the fires are subjected to high temperatures and consequent expansion strains. This means that great care must be used in setting up any moving parts that are close to the fire.

The stoker parts are mostly of unfinished castings, but this is no reason why erectors should not use great care in lining up and adjusting the working parts of the stoker; in fact, because the stokers are made of rough castings, are subjected to high temperatures, is all the more reason for taking great care in lining up and assembling the various parts.

Fuel Supply

It is generally conceded that the cost of fuel has permanently reached a higher level, not only due to the cost of mining, but to transportation, and the users of fuel should interest themselves in means and methods to counteract the increasing costs.

There are several ways in which this result can be accomplished, such as:—

More efficient methods of mining and handling of coal at the mines;

Limited storage of coal at the mines, to overcome unequal car supply;

More efficient methods of transportation by "zoning" the use of coal from each district so far as possible.

Creating storage at the consumer's end and taking coal in more regular seasonal quantities, thereby giving the railroads a higher use factor of locomotive and rolling equipment.

This would also allow the mines to work regularly and tend to decrease the miner's wage as, if fewer miners were used regularly, they could afford to accept less hourly wage.

The cost to the consumer of high ash content in coal is not fully appreciated.

In Cincinnati, under the cost of coal and transportation obtaining there, the difference in value between coal of 5 per cent ash and 20 per cent ash is $1.29 per ton, without allowing for increased cost of capitalization for plant due to decreased capacity with high ash content coal.

We have heard a great deal during the past year about powdered fuel, and the statement from some quarters that the stoker will be replaced by some form of powdered or pulverized fuel burning. There is no question but that powdered fuel has been demonstrated to be practical and that coal of low quality can be burned efficiently by the powdered fuel method.

The engineers who have had the courage to develop powdered fuel burning to its present state of practicability, deserve a great deal of credit. The engineering problems involved have been handled with marked ability and the value of this contribution to modern power plant engineering can hardly be over-estimated. But, thus far, I have been unable to find a single powdered fuel plant obtaining a better average over all economy than that obtained by the better types of stoker installations.

It is true that powdered fuel plants have obtained efficiencies that a stoker plant could not obtain with the grade of coal used, but, thus far, powdered fuel plants have not shown a higher maintained economy than the modern stoker plants when coal of average quality that can be successfully burned on stokers, has been available.

At the Cincinnati plant, we obtain an overall monthly efficiency of from 76 to 80 per cent including banked hours. The average boiler h.p. rating will be over 200 per cent and we regularly operate the boilers on peak load up to 300 and 350 per cent of rating. I do not know of a powdered fuel installation successfully operating at 300 per cent of boiler rating. We hear a great deal about what they expect to do, but it is important to distinguish between prospects and actual experience over extended periods of operation.

It would, therefore, appear that the conditions under which the powdered fuel plant is a competitor of the stoker, are:—

1. Where a supply of low grade coal is available that cannot be efficiently burned on stokers, and that can be delivered at the plant at a cost sufficiently low to justify the investment and maintenance cost of a powdered coal plant; and,

2. If the powdered fuel system is developed to a point where it can show a higher maintained, overall efficiency than the stoker, then high fuel cost would become a factor, but the saving in fuel would have to be sufficient to more than balance the cost of preparation of powdered fuel and increased investment. We should also consider the added complications of equipment and operation with powdered fuel burning, with the consequent liability of trouble.

The investment of the powdered coal plant should include the extra investment in boiler plant necessary, due to the lower capacities obtainable with powdered fuel as compared to a modern stoker installation.

For the purpose of testing the valve, water was, for the first time, turned into the penstock of No. 1 generator at the Chippawa development on Tuesday. Formal opening of the plant is expected to take place on December 28th or 29th. There is some concreting work to be done, removal of wood structure and machinery before actual completion of the work.

Fuel Saving In Relation To Capital

Investigation Shows Economy Resulting From Use of Efficient Equipment—Concrete Illustrations Given in Support of the Theory Under Discussion

By JAMES A BRADY*

SOMETHING definite and reliable in the way of information for the enlightenment and guidance of the prospective investor in efficiency equipment seems to be needed, and the object of this paper it to provide evidence to support the rather general understanding that it pays to economize. The author's original opinion was that there would be no difficulty in obtaining an abundance of first-hand information from engineers and owners who have recently installed efficiency equipment. These men invariably express satisfaction with the outcome of their endeavors, and it was thought that a compilation of such evidence would be the best possible manner of presenting this subject to the public.

In furtherance of this idea, numerous letters were written to consulting engineers, chief engineers of power plants, and owners, stating the desire of the author to secure such data. In all cases, with about three exceptions, the replies were similar, and to the effect that, while they had done this class of work, they had no records or data on which to base any figures, and they were therefore, unable to provide the information requested. This in itself seems to be a fitting subject for serious thought.

Engineers in general are supposed to work along lines of precision and not guesswork, and it seems rather like an unfavorable commentary on the profession, as a whole, to state that less than five per cent. of those corresponded with were able to furnish any data at all. It seems necessary, therefore, to draw upon the experience of the few having such data and let these specific instances form the starting point for what is hoped will develop into a strong body of testimony in favor of efficient methods.

Let me first present a theoretical discussion which forms, in all cases, the nucleus of the whole matter. Consider a unit of 500 h.p. to be operated at 200 per cent. of rating over 10-hr. manufacturing period with coal used for starting and banking, which brings up the total coal equivalent of 12-hr. at double rating. This then requires 12,000 boiler h.p.-hr. per day, which, at 4 lb. per h.p.-hr. amounts to 48,000 lb, or 24 tons of coal. Now, assume that the more efficient equipment will either utilize an equal tonnage of a grade of coal costing one dollar less per ton, or by an increase in efficiency reduce the amount of coal actually used by an amount which is the virtual equivalent of the one-dollar differential. We start, then, with either a direct decrease in coal cost or an efficiency producing a differential or saving of one dollar per ton. Twenty-four tons at one dollar would provide a net saving of $24 per day.

Now, the investment necessary to save this amount, we will say, is made up as follows:

One mechanical stoker	$5000
Fans and installation cost in excess of equivalent hand-fired setting	2000
Total	$7000

This amount of $7000 divided by 24, gives 292 days as the time required for completely recovering the initial investment. This is approximately the number of working days in one year, so that in this case, it could be stated that the investment provided a return of 100 per cent. per annum. Should there be a greater or less differential in the price of coal or in the efficiency, this figure must be modified accordingly, or if there is a greater cost initially, the returns would be correspondingly diminished; but assuming that this is substantially correct, the dividends are of such magnitude as to overshadow any other form of investment other than finding the money or striking oil. It can be reduced to one-half or one-third of this figure, and still loom up as a phenomenal return for any concern, however prosperous. It is more than improbable that any such return can be secured by investing the same amount of money in equipment directly providing the output of the institution in queston.

To support this by specific evidence, the author presents a few concrete illustrations. The power plant of the Waterloo, Cedar Falls and Northern Railway Company was overhauled in the fall of 1913, and the author followed this installation through for some two years thereafter.

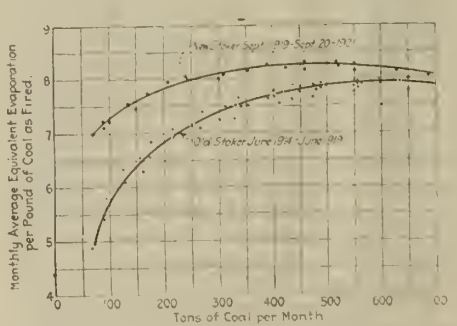


Fig. 1.

Two of the resulting curves are shown in Fig. 1. In this case there were four 500-hp. boilers installed, replacing older water-tube boilers which were also fired with the same make of stoker. With the same stoker, the same fuel, and similar boilers the savings may very definitely be attributed to the greater efficiency secured by the then more modern setting. Not only was the furnace better proportioned and much more ample, but efficiency equipment was installed, such as gas-analysis recorders, draft gages, recording thermometers, feedwater heaters, and coal-weighing equipment. A simple system was developed for watching the indication of these instruments and drawing therefrom the logical deductions. In this particular instance, the new equipment actually paid for itself in a little over a year's time. It will be observed that the coal cost per kw-hr. was just about cut in two.

During the summer of 1919 the Armour Institute of Technology made a change in their mechanical stokers from the old-style chain grate to the new traveling grate, boiler and other conditions remaining exactly the same. The modern stoker had a better grate ratio (70 sq. ft. grate surface as against 90 sq. ft.) and was designed to be more efficient at the lower ratings which occurred during the major portion of the year. Only for about two months in the year was the boiler worked up to anywhere near its capacity. Natural draft was used throughout this period—chimney 175 ft. high. The average pressure was 100 lb. gage and the average feedwater 198 deg. Fahr. The remarkable result of this change is best shown in the curves in Fig. 2, furnished by Professor Gebhardt, and in the accompanying data in Table 1. Owing to the fact that no change was made in this case other than the stokers, we can safely attribute the improvement to the improvement in the stoker. Figuring on the basis of Cartiervi.le, Ill., No. 3 washed nut coal at $5.67 per ton delivered to the boiler room floor, an annual gross saving of $1553.58 was realized on the total saving of 274 tons of coal. The average cost of repairs to date is $50. The approximate price of the new stoker was $3500 and the installation cost $1000, making a total of $4500. The return on the investment is therefore 33 and one third per cent.

By a change in the brickwork surrounding the boiler, both of these improvements were accomplished. Examining the boilers it was found that

*Vice-President James A. Brady Foundry Co., Mem. Am. S. E., presented at the annual meeting A.S.M.E.

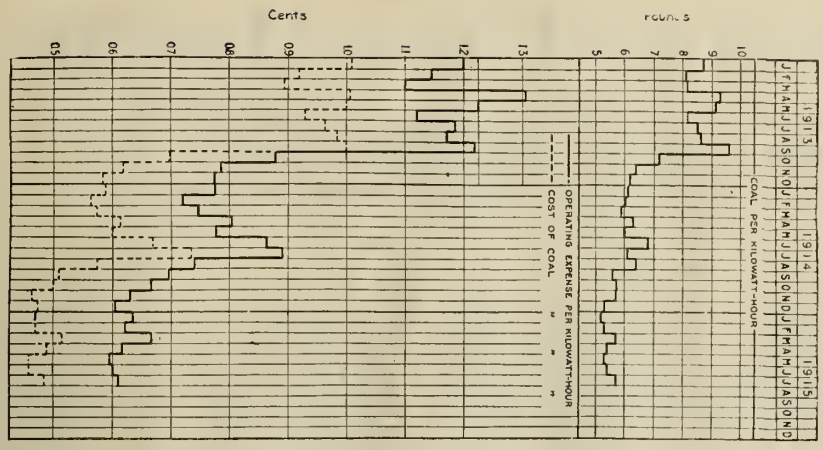

Figure 2

there was insufficient circulating space between the tubes; this was corrected by removing one of the center rows and several tubes at the sides, which too closely approached the shell. These changes provided circulating space for the downward and upward flow of the water.

A third instance of a quite different nature is exemplified by the work of Neiler, Rich & Co. at the University of Chicago during the past season. The boiler room here consists of a number of 72-in. by 18-ft. horizontal return tubular boilers, stoker-fired, and using the usual run of bituminous coal that comes into the Chicago market. Considerable difficulty was experienced in carrying the 1919-1920 load on twenty boilers. Neiler, Rich & Co. undertook to keep this plant in operating condition until a new plant could be completed, so that what was done was merely for the purpose of keeping things going until that time, and not with the idea of a permanent improvement. No attempt was made to change any of the equipment, but it was found that the draft loss due to circuitous gas passages was very great, providing insufficient furnace draft. The combustion chamber was entirely too small, so that attention was given to improving these conditions.

Apart from patching up the brickwork, covering pipe lines, etc., nothing else was done; but it was found that these changes enabled the engineer to carry a somewhat increased load on fourteen boilers. The same coal was used, and the same chimney and breeching connections were retained, so that in this instance the economies are properly credited to improved boiler circulation, furnace draft, and combustion space. The coal saving is not proportional to the number of boilers used, because the better circulation in the boiler enabled higher capacities to be carried. Very accurate figures are not available in this instance, but it is beyond controversy that the cost of the improvements made will be covered by the fuel saving, within the period of two heating seasons.

CAMERA TO HELP SAVE COAL

Savings in coal consumption may be effected through the instrumentality of the motion picture camera, it was said at a meeting of the American Society of Mechanical Engineers. The camera has been used to record the phenomena of combustion in big furnaces at a range so close that the eye could not withstand the heat long enough to make the necessary observations. Motion pictures of coal combustion taken under the highest temperatures were exhibited by R. Sanford Riley, manufacturing associate of the inventor of a special camera designed to make pictures in a blast furnaces, glass furnaces, gas and other similar plants.

Professor A. G. Christie of Johns Hopkins University condemned "quantity production," in American colleges, and C. F. Pratt of Schenectady, representing the General Electric Company, said that a survey of the plants of his company would show that "our educational institutions are developing young men of real ability for the industry." Professor Christie quoted Dan F. L. Bishop of the University of Pittsburgh as having said that there was no first-class engineering school in America. He said that this view was supported by Professor Comfort A. Adams of Harvard, formerly Chairman of the National Research Council. Professor Christie urged the adoption of a national policy on engineering societies. He said that the Engineering Department of Johns Hopkins was endeavoring to raise standards by limiting attendance among the upper classmen to a small number.

TREATING ASHES TO SAVE UNBURNED FUEL

Washing tests made in the laboratory of the mining department of the University of Illinois show the possibility of recovering the unburned fuel by crushing the refuse to 3-8 in. ring size, washing on coal-washing tables, and removing the slime from the washed product by a dewatering conveyor elevator or a screen. The coal-washing table is a standard-piece of coal-washery equipment, similar to the concentrating table commonly used in ore-dressing plants.

Two washing tests were made, one being with 3-8 in. mesh screenings from the general sample, and the other with the over-size crushed to pass a 1-4 in. round-hole screen. Combining the results of these two tests gives the average results for the entire sample of refuse as received from the powerhouse. The total combined yield of washed fuel was 20 per cent of the gross weight of refuse treated. The washed fuels had an ash content of 25.5 per cent and an average calorific value of 9754B. Th. U. The heating value of the dry screenings ordinarily fired at the plant is about 10,000 to 11,000B. Th. U., and the ash content 18 to 22 per cent. At a great many plants the boiler-furnace refuse contains a larger percentage of recoverable fuel. Operation of a table washery on refuse such as is produced at this plant would result in the production of one ton of fuel from each five tons of refuse handled.

The equipment required for a simple plant of this size consists of a corrugated roll crusher to which the refuse is fed by a chute direct from the power plant. The crusher should be set to crush the refuse to about 3-8 in. maximum size. The crushed material is stored temporarily in a feeder hopper of about five-tons capacity, from which it is fed to a washing table by a short screw conveyer. Two inclined dewatering drag conveyers elevate the recovered washed fuel and also the discard from collecting sumps to their respective storage bins, and at the same time remove the water and fine slime.

Operation of such a plant would require only a part of the time of one man, as a coal-washing table needs only occasional attention after it is started and properly adjusted. In most cases the freight charges on coal purchased to replace this recoverable unburned fuel would be more than sufficient to cover the cost of operation.

BULLETIN

The Underfeed Stoker Co. of America have issued a bulletin describing the new side dump underfeed stoker. Instead of the hand cleaned side plates as fitted in the ordinary hand cleaned stoker, dumping side plates are fitted, which are operated by levers from the stokehold floor. The new stoker has been designed to meet the need of a cheap installation of a self-cleaning stoker. In all other respects it is similar to the usual underfeed handcleaning stoker The bulletin is fully illustrated and the apparatus is well described.

ANNOUNCEMENTS

The Superheater Company Montreal, announce that they now have an associate connection in Paris. This office will operate under the name of Le Compagnie des Surschauffeurs, and this company has been given full, rights for the sale and manufacture of "Elesco" return bends, superheaters, and other "Elesco" products. The company is located at 11 Rue Scribe, Paris France, with a factory on the outskirts of Paris.

The Simplex Iron and Tool Co., has been incorporated to manufacture adjustable wrenches. They are located at 216 Adelaide St., W., Toronto, and Mr. Dunlop, president of the Dunlop Coal Co., is also president of the above mentioned concern. Mr. Harington of the Harbor Commission, is vice-president of the new firm.

The Lubrication of Prime Movers

The Question of Lubrication in These Days of High Speeds and High Temperatures Is Somewhat More Difficult Than Formerly—Some of the Factors Leading to Success Are Given in the Following Article

By C H. BROMLEY

OF ALL prime movers the steam turbine presents the severest condition for the lubricant. The journal speeds are higher than in any other class of machinery; the bearing pressures are relatively low, yet they are great, and becoming greater; the temperature, particularly of the bearing adjacent the high-pressure end, also the thrust bearing, is extremely high, even normally. Total steam temperatures at the throttle of between 600 degrees and 700 degrees F. are becoming common. Heat at this temperature is conducted to these bearings in addition to the heat of friction generated in the bearing itself. The oil circulates to the bearings rapidly—from 7 to 40 times per hour.

With these conditions to be met, the lubricating system must function so that at no time, not for a fraction of a second, shall there be metallic contact or metallic friction between the journal and the bearing shell. I know of no case where metallic friction has occurred that severe damage to the turbine did not result. The oil-pressure varies from 2 to 15 lb.; usual oil temperatures are between 130 degrees F. and 180 degrees F. Thrust-bearing temperature is usually—2° degrees F. higher than that of other bearings, except the high-pressure end bearing.

Oils for Steam Turbines

Our experience, as well as that of others, shows that for steam turbines nothing but a straight-run mineral oil will do. It must not be compounded or blended with any product, not derived from crude petroleum. There should be no animal or vegetable fats in it. Water will get into the lubricating oil in a steam turbine, however careful the design and machinery of the unit, and however cautious the operator. And oil containing animal fats will emulsify and form sludge so badly as to be dangerous. The Prime Movers Committee of the N.E.L.A. in its 1921 report, page 6, well states it as follows: "Compounded oils are not to be considered, as turbine oils should be strictly pure, neutral mineral oils, without any admixture of animal or vegetable fats." The flash-point, open cup, should not be lower than 315 degrees F. for extra-light oil, to 335 degrees F. for medium. High flash-point is desirable, as it indicates slow evaporation and ability to retain original viscosity, provided also that the oil is slow to oxidise.

There is still much to learn about viscosity for turbine oils. However, the safe guide limits now are 110 secs. to 350 secs. Saybolt at 100 degrees F. The higher the speed the lower the viscosity may be. I have heard of excellent results with oil of 80 secs. viscosity. While this may be "sliding on pretty thin oil," to paraphrase an old expression, it is probable that we will eventually discover that there is no need for as much apprehension about thin oil for turbines as is now general. What chiefly concerns us is the viscosity at normal operating temperatures, and the ability of the oil to retain its viscosity throughout a long period of service.

Emulsion and Sludge

Emulsion and sludge form one of the chief worries of the turbine operator. If allowed to accumulate, they make impossible safe operation of the turbine.

An emulsion is a mixture of liquids, insoluble in one another, where one is suspended in the form of minute globules; also it is a mixture in which air and solid particles, or both, are suspended in a liquid. The turbine oiling system is practically ideal for promoting the formation of emulsion. Water and moisture will get into the oil from leaky shaft glands, leaky oil-cooler coils, and bearing cooling coils where water-cooled, also from the atmosphere. The churning to which the oil and water are subjected in the circulating system forms an emulsion wherein the particles are very finely divided. Obviously the pressure oil film in the bearings will be seriously impaired by such an emulsion, and the risk of serious damage to the turbine will be imminent.

Sludge is that nasty, brown-blackish substance one finds in the turbine-oil reservoir, oil cooler and oil piping. It is the result of oxidation of the oil. If emulsion is allowed to accumulate, it soon results in sludge. The unsaturated compounds in the oil are more rapidly oxidised, and the metallic particles, dirt, dust, etc., apparently act as catalytic agents, for the formation of sludge increases at an accelerating rate with the formation of organic acids.

Standard of Demulsibility

It is up to turbine operators to demand the adoption by engineering societies of some workable standard of demulsibility for turbine lubricating oils. The term "good" demulsibility means nothing to an engineer, yet that is about all the information generally available.

Here is a way to make the Bureau of Standards test for demulsibility that is practicable: Apparatus necessary—a malted-milk mixer such as used at soda fountains, a thermometer, a 100 c.c. graduated vial, and an electric hot-point or other means of heating the sample. Mix 40 c.c. of water at 55 degrees C. (132 degrees F.) with 20 c.c. of oil. Keep the mixture at 55 degrees C. and emulsify in the mixer for five minutes. The number of cubic centimetres of water that settles out in one minute multiplied by 60 (the number of minutes in one hour) equals the standard demulsibility number for the oil. The perfect number is 1200, being 20, the total water volume, multiplied by 60, the total number of minutes in one hour.

Where the oil is continuously kept clean, as in the continuous bypass system, the acid content seldom, if ever, gets over 1 per cent, even after years of service of the oil. In fact, analyses have shown less acidity after two years' continuous use of oil purified by the continuous bypass system than the oil contained originally. The explanation probably is that the acid is entrapped in impurities in the oil, and the continuous removal of these keeps down the acid content.

Methods of Maintaining the Quality of Turbine Oil in Service

We may disregard sweetening and merely add make-up oil, because in modern practice, particularly with turbines of from 700 kw. capacity upward, no one would think of trying to keep the oil in good condition by such means. To attempt to do so is to fail, because one merely dilutes the impurities; they are not removed.

Batch filtration was universally practised until a few years ago, or until the advent of the continuous bypass system. Batch filtration was a decided improvement over sweetening, but it has several objectionable features. The entire oil charge is drained at intervals—when, rests entirely upon the operator's judgment and upon circumstances which may delay the cleansing of the oil until long after it should have been done. The quantity of oil in reserve must be large. The really serious objection is that batch filtration does not prevent the accumulation of emulsion and sludge.

When considering turbine-oil purification, the average engineer thinks of oil loaded with emulsion, filth and sludge. He must see it differently, for with modern means available the oils never get unfit, provided the right oil has been selected, the oil reservoir and piping are clean to start with, and water and steam leakage from shaft glands, cooler, and other sources are kept down, as they can and should be.

This system of purification, adopted as standard by one large builder of turbines and highly endorsed by all other turbine builders and leading oil companies, consists of a sight over-flow, a filter, an oil pump, and the necessary piping. The vented sight overflow is connected directly to the turbine-oil reservoir, so that its overflow level corresponds with the desired oil level in the reservoir. The outflow of oil from the reservoir is automatically controlled by and is equivalent to the amount of oil delivered by the filter pump from the filter to the reservoir. Should this pump stop for any reason, the turbine continues to operate as though no system were installed, as this system is entirely independent of the self-contained oiling system of the turbine furnished by its builder. It is plain that a

*A paper read before the System Operators' Association.

certain percentage of the total oil charge is passed through the filter per hour, and that purification of the whole charge is continuous. Emulsion and sludge cannot accumulate, as they are removed as fast as formed. At first one is likely to say that with this system clean oil from the filter is put into the dirty oil in the reservoir. The answer is that with this system there is no dirty oil either in the turbine reservoir or the filter.

Diesel-Engine Lubrication

Diesel-engine cylinders cannot be successfully lubricated by methods satisfactory for steam or air engines. Unless application of the lubricating oil is timed for a particular part of a particular stroke, there is every likelihood that, without extravagant use of oil, the lubrication will be burned away before it has time to function as a lubricant.

In the practice of one of the leading Diesel-engine builders the oil is delivered to the piston through the cylinder wall at two places 180 degrees apart. For the piston pins the oil is fed through the cylinder wall into a slot in the piston which comes even with the oil hole when the piston is on its lower centre.

The lubricator uses alternate forcing plungers on opposite sides of the gear or plunger-actuating shaft; thus any two adjacent plungers force oil when 180 degrees apart. By arranging the feeds in groups, each group on a separate gear-shaft, and the shafts driven through gears or eccentrics or chains from the engine, any desired timing of delivery may be had. Ordinarily, the lubricator has a layshaft and three eccentrics set 120 degrees apart; the lubricator gear-shaft is so divided that eighteen feeds are driven in sets of six to each eccentric and of these six feeds three plungers are on one side of the gear-shaft and three on the other. The lubricator has a divided oil tank to permit of using a different oil for the air compressor of the engine.

The oil is delivered among the piston rings on the lower centre at the end of the power stroke. This ensures thorough coating of the cylinder wall before the power strike, during which the cylinder temperature is greatly increased owing to combustion.

Usually the crankpins and main bearings are lubricated by a gravity system which supplies the oil through gang sight-feed oilers, located on the engine frame columns.

A leading builder uses two feeds for each main bearing, and one feed for the centrifugal oiler for each crankpin. All oil fed to these bearings and to the piston pins is caught in the engine base. One end of a small double pump delivers the oil to a filter conveniently located, the other end taking it from the clean-oil compartment of the filter and delivering it to a tank at such elevation as to give the desired pressure at the sight-feed gang oilers feeding the bearings.

Camshaft rollers are grease lubricated by hand-operated cups and valve tappets and rockers by oil from a squirt can. These could be automatically lubricated like the rest of the unit, but is purposely not done so, to ensure attention and watchfulness on the part of the operator.

In marine practice practically the entire engine is force-feed lubricated at low pressure. A tank in the ship's double bottom holds the oil supply. A circulating pump discharges into a cooler and then into a main parallel with the engine bed; branches from the main supply each main bearing and the thrust bearing. Holes in the crankshaft register with circumferential grooves in the main-bearing shells and feed oil to crankpins and piston pins.

Practice in Marine Diesel Engines

The usual precautions are, of course, necessary to prevent leakage of salt water into the oil reservoir or sump, and into the oil supply from the cooler. Here pistons are oil-cooled and the crankpins and piston pins are supplied with oil through holes in the crankshaft and connecting rods, trouble is likely to arise owing to carbonised oil flaking off and clogging the oil passages.

These engines are, of course, tightly enclosed and bearings cannot be felt for temperature. A thermometer in the oil-return pipe will indicate a serious temperature rise, but will not indicate the bearing affected. Various jimcracks to indicate such have not been very successful. Care is therefore necessary to adjusting bearing clearances and keeping the oil, oil tank, and passages clean.

Reclamation of Internal-combustion Engine Lubricating Oil

Naturally, because of the high temperature, considerable carbon is formed. When the oil is too heavily loaded with it, the carbon must be removed. This carbon is extremely fine. Filtration alone or centrifugal separator alone does not remove it all satisfactorily. The best results are obtained by the use of the reclaimer.

This reclaimer is in the form of a cylindrical shell. The dirty oil is heated by steam at 212 degrees or higher to bring about a satisfactory difference in the specific gravity of oil and foreign articles and water. After the heating period a coagulant is mixed with the oil and the mixture allowed to settle. Usually a batch of oil is reclaimed every twenty hours. After settling is completed it is best to allow the oil to run through a filter, which is readily attached to the reclaimer. These reclaimers are built with electric-heating elements where steam is not conveniently available.

ECONOMY IN THE BOILER-HOUSE

Below we reproduce a diagram for the guidance of boiler-house staffs, issued by the Fuel Economy Committee of the Federation of British Industries, 39 St. James's-street, London, S.W.I. The diagram can be obtained printed on metal plates 20 in. by 30 in. for hanging in the boiler-house.

1. Avoid wastage of cinders in the ashes by cleaning the fires carefully and by using suitable firebars.
2. Avoid production of black smoke and incompletely burnt gases by regularly and frequently firing coal in small quantities. Keep a proper depth of fire.
3. Regulate the draught by the damper to reduce the excess air. Try to obtain 12 per cent CO_2 in the chimney gases.
4. Keep the grate properly covered with a level fire. Use the rake when necessary for this purpose.
5. Examine the boiler setting carefully for air leakage, particularly furnace doors, cracks in the side walls, joints between the boiler shell and brickwork, and the damper slides.
6. Keep the boiler surfaces free from soot and flue dust.
7. Keep the internal boiler surfaces free from scale.
8. Do not force the boilers unnecessarily.
9. Examine the seating blocks and partition walls carefully. Repair if necessary to avoid by-passing.
10. Lag the exposed surfaces of boilers and steampipes efficiently.
11. Avoid excessive blow-down.
12. Keep the boiler filled to the working level by a continuous and steady feed.
13. Avoid leakages of steam from boiler fittings and valves.

Word has been received from Montreal that the International Paper Co., is planning to start its newsprint mill at Three Rivers, Quebec, during the month of February. It is understood that the initial production will be 100 tons a day from two machines with a capacity of 50 tons each. It is planned to increase this amount shortly, if the market warrants, by another 100 tons a day, making the total production 200 tons a day, or 60,000 tons per year.

The Season's Greetings

TIME IN ITS steady course has once more brought round the season when it is a pleasant privilege to wish our readers the greetings of the Christian peoples. It is with sincerity and heartiness that we take the opportunity of wishing you, collectively and individually, a "happy Christmas and a prosperous New Year."

It is unfortunate, but inevitable, that a good many engineers are unable to spend the whole of Christmas Day with their families, but somebody has to be in charge, holiday or high day, where steam has to be kept handy. This is a necessity unavoidable. However, it can usually be arranged so that each man can spend a part of the day at home, and the dinner hour can be made to suit him for that one occasion.

Again, there are those who prefer New Year's Day to Christmas Day for their celebration, notably those whose ancestors or themselves come from the north of the Tweed. There are pleasant customs associated with New Year in some parts of the country which give it a charm of its own. For instance, in Quebec, one is privileged to kiss the matron or maid who opens the door when making a call on New Year's Day, and many can testify with pleasure to the excellence of this idea. In fact they would like to see it more generally adopted, and with the gradual spread of brotherly and sisterly feeling, who knows?

This is a time of prospect and retrospect. Probably the most important feature of the past year or two from the stationary engineer's standpoint has been the working out of the graded certificate law, and in our opinion, taken as a whole, it has worked for good. There are many phases of its operation which have perhaps made for injustice, but considering how radical a departure from previous practice it was, this was perhaps only to be expected. We believe that it has accomplished one of the principal reasons of its creation, that is the raising of the standard of education from an engineering viewpoint, of those who come under its jurisdiction.

While it is difficult to judge from the individual, it is easy to see the trend of events as reflected in the attitude of those societies formed of and devoted to the interests of the stationary engineer. In the case of the Canadian Association of Stationary Engineers, a very definite and wide-spread movement for better education has been developed. Every encouragement is being given to the members of the various lodges, not only to improve their own standard, but to raise that of every member by mutual help. Competition has been stimulated, and assistance of a material nature has been afforded by firms engaged in the manufacture and sale of the appliances operated by the stationary engineer. Another strong and representative body of engineers,—the Universal Craftsmen's Council of Engineers, have also adopted a policy of education with their other activities.

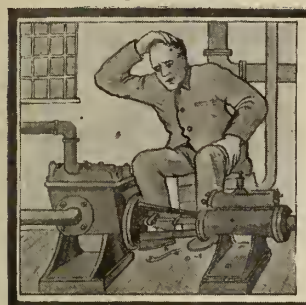
The action of these two societies must be reflected among engineers in general, because it is a fact, that as a man becomes imbued with greater knowledge of his profession, he becomes broader-minded, and more willing to share his knowledge with others less fortunate. The old retarding spirit which urged a man to guard his painfully acquired knowledge as a possession that belonged to him alone is fast disappearing. It was a wrong spirit, and tended to a narrow-minded and self-centred viewpoint which worked against the best interests of the possessor himself and those with whom he came in contact. Stationary engineering practice is to-day such a diversified thing that no one man can expect to know it in all its ramifications. It is only by sharing his knowledge of his particular branch, and getting in exchange the experience of others familiar with different practice, that he can round out his grasp of the essentials.

We hope that every engineer will start the New Year with the firm intention of adding to his own knowledge, and at every opportunity, to that of others. By consistently following out this policy, he will be building up a standard of efficiency among engineers in general which will re-act to the good of the whole profession, and make the passing of examinations a simple and pleasing task. Have no fear that it will result in making every man as good an engineer as the next, for in the course of human events, there will always be, in every line of endeavor, men who stand out from the others. Starting with the same education and advantages, there are inevitably men whose native abilities enable them to make a better use of the materials at their hand, and whose keener insight will grasp an opportunity unseen by their fellows.

From a personal standpoint we feel that we have come closer in the past year to our readers and contributors than we were a year ago, and by their help have been able to give them a stronger and better paper than ever before. It will be our endeavor to so continue in the year to come that "Power House" will retain the respect and loyalty of its readers. It is our aim to serve their interests in such a way as to receive continued co-operation.

A Scientific Institute

ACCORDING to information received, Baron Edmund De Rothschilds, administrator of the Eastern Railway of France, has given ten million francs to found a scientific institute, the object of which is to encourage students to take up research as a career. Particular attention is to be given to researches looking to the application of science to industry and agriculture. The institution is to be managed by a council, two members of which are elected by the Academy of Science and the French Museum.



OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

WORK DONE BY AMMONIA MACHINE

Question:—In a direct expansion system of refrigeration how would you calculate the amount of work that the machine was actually doing?

Answer:—The actual work done by an ammonia refrigerating compressor depends upon the volume of gas pumped per hour, and its cooling effect. These quantities vary with the condensor and evaporator pressures but a typical case can be illustrated which will show the general principles governing the calculations.

Take a compressor of 7½ inches diameter by 10 inches stroke, running at 75 strokes per minute, with an absolute condensor pressure of 125 lbs. and an absolute evaporator pressure of 41 lbs. From tables compiled by various authorities on the properties of ammonia we can ascertain the volume of gas handled, and its cooling effect per lb. at the temperatures and pressures named.

Ammonia gas at a pressure of 41 lbs. absolute has a temperature of 12.2 F. above zero, and a volume of 6.99 cubic feet per lb. Its latent heat is 562.6 B. T. U. Assuming that the temperature of the liquid in front of the regulating valve is 68 degrees F., then before the liquid evaporates after passing the expansion valve, it will give up the difference between the 68 degrees and the evaporator temperature, or if a direct expansion system the difference between 68 degrees and the surrounding air. The temperature corresponding to 41 lbs. being 12.2. we can assume that the surrounding air is at 10 degrees higher say 23 degrees. That means that 45 B. T. U. approximately will be given up to the surrounding medium, and this amount must be deducted from the latent heat of vaporisation to get the true cooling effect per lb. of gas. If the latent heat is 562.6, then the cooling effect will be 517.6 B. T. U. per lb.

The weight of gas passed through the machine per hour will be the stroke volume per hour, multiplied by the weight of ammonia gas per cubic foot at the evaporator pressure. The stroke volume will be

$$\frac{7\frac{1}{2}\text{x}7\frac{1}{2}\text{x}.7854\text{x}10\text{x}75\text{x}60}{1728}$$

and this multiplied by .143, the weight of a cubic foot of gas at 42 lb. absolute will give the weight per hour. This again multiplied by the cooling effect per lb. ammonia will give the cooling effect in B. T. U. per hour. This multiplied by 24, the cooling effect per 24 hours, and divided by 140 x 2000 which is a ton of refrigeration will give the amount of work done in refrigerating tons per day.

$$\frac{7\frac{1}{2}\text{x}7\frac{1}{2}\text{x}10\text{x}75\text{x}60\text{x}.143\text{x}517.6\text{x}24}{1728\text{x}140\text{x}2000}$$

This works out at 7.299 tons. Dividing 280,000 by the cooling effect of one pound of ammonia we arrive at the weight of ammonia to be circulated for one ton of refrigeration. That is

$$\frac{280{,}000}{517.6}=540.9 \text{ or } 541 \text{ lbs ammonia}$$

per ton of refrigerating effect.

Lorenz gives as the minimum horse power for 100,000 B. T. U. per hour cooling effect, 4.98. This will be increased by various factors, such as resistance of valves, etc., from 7.5 to 15 H. P. per hour according to this minimum figure is 17,100. This is based on a temperature of 68 degrees in front of the regulation valve. It will be seen that cooling the liquid leaving the condensor to a temperature lower than 68 will increase the cooling effect of the gas as the nearer the temperature of the liquid is to the temperature of the evaporator, the less heat will be given up to the medium surrounding the coils, and the nearer will the cooling effect come to the actual latent heat of the liquid. This calculation also shows that the higher the back pressure, the greater the density of the gas entering the compressor and the greater the weight of gas handled per stroke. The closer the condensor pressure is kept to the evaporator pressure the less work will have to be done by the compressor, and the higher the efficiency of the machine.

LIQUID LOW IN RECEIVER

Question:—I understand that the liquid line in the receiver extends to within four inches of the bottom, and that the liquid should be at all times sufficient to cover the bottom of this pipe. What would be the effect if the liquid got below this point?

Answer:—The effect of the liquid line being uncovered would be to fill the line with gas instead of liquid passing through the evaporator regulating valve, or the expansion valves in a direct expansion system, only gas would be passing through. The immediate effect would be to raise the temperature in the evaporator or in the direct expansion coils, and a loss of cooling effect. It is the extraction of heat by the vaporisation of ammonia liquid into a gas that gives the cooling effect, and if gas instead of liquid is passing the regulating valve, these is no possibility of cooling. It might seem at first glance as though the liquid receiver would become cold, and really act as an evaporator. There would be a certain amount of cooling effect in the receiver under these circumstances, but owing to the relatively small amount of liquid evaporating, this would not be very great. As a matter of fact, in practice, a shortage of liquid can be detected by the fluctuation of the discharge pressure gauge, the sound of the gas passing through the expansion valve. and the general behaviour of the machine.

CARE OF BOILER

Question:—Would you kindly inform me through the columns of your valuable paper, the proper method of caring for a steam boiler after being in use. Also the best condition to leave same when not in use. Also what is the shortest possible time in which to bring a 150 H. P. boiler from cold water to temperature to sufficient heat to generate steam without doing injury to same?

Answer:—In preparing a boiler to go out of commission, the first thing to do is to burn the fires down, so that all the combustible in the coal is consumed and there is nothing left to pull out but the ash. The boiler should be used to supply steam to some auxiliary or heating system until the pressure is all worked off when that is possible. When the pressure is all gone a valve on top of the boiler should be left cracked to prevent the forming of a vacuum in the boiler, and the water should be left in the boiler until the brick work of the setting has cooled down sufficiently to prevent any danger of burning the sheets when the water is emptied. This may take from eight to twelve hours; and during this cooling process the main damper should be open just sufficiently to create a gentle draught through the furnace and setting so that the radiant heat from the brickwork can be carried away. When satisfied that everything is cooled

down sufficiently the top manhole can be knocked in, first making sure that there is a valve open for the admission of air, and no vacuum is formed in the steam space. This can be ascertained by opening the drain at the bottom of the water column, and noting if the water flows freely. If it does it is all right to go ahead, but if not, the top connection to the gauge column, and one of the try cocks may be left open, or the safety valve eased back, or any other method of establishing communication with the atmosphere that presents itself may be used. When knocking in the top manhole door of a boiler that has just been put out of commission, a stout rope should be fastened to one of the manhole door studs, and secured to a handy steam pipe of some fixture, so that when the dogs are taken off, the man doing the work can stand clear of the door, and tap it in with the end of a long bar. The rope will hold it when it swings in, and prevent it from dropping heavily on the top row of tubes, and probably damaging them. If the boiler contains a quantity of hot vapor, which is often the case then the man is well out of harm's way, and stands no chance of being burnt. The manhole door being off, the next thing is to open the blow off pipe, or if fitted with a circulating device, the surface blow off, and let the boiler drain out by gravity. It is a very good plan while this is going on to get the hose rigged, and follow the course of the descending water with a good jet from the hose, washing the loose sediment from the shell and tubes before the heat in the metal has a chance to bake it on. Having got all the water out, the lower manhole or handhole doors may be taken off, and the boiler left standing till cool enough to be entered with some degree of comfort. A thorough examination of the interior of the boiler should be made, and all traces of oil or grease removed, examination made for signs of corrosion, (pitting), and any scale that may have accumulated on shell-heads or tubes removed as far as it is possible to do so. The stays should be tested by tapping with a hammer, and the outlets to the water column examined to make sure they are clear. Externally the brick work should be examined, the nipples where feed and water column connections enter the shell carefully looked at, blow off examined, and the rivet seams looked over for such defects as fire cracks or leakage. After necessary repairs are made the boiler is ready for filling and placing back in commission.

If the boiler is going to be permanently laid up, the following procedure is recommended. Remove all ash and clinker from furnace, and soot, etc., from the back ends. Take a good steel wire brush and remove all the deposit from the tube plates both front and back and also from the shell over the furnace and combustion chamber. Any brick work that may be defective and can form a harbouring place for moisture should be pulled down clear of the metal. If the boiler is going to be in a warm boiler room all the time it is closed down, these precautions should guard against oxidisation or rusting externally. Where there is no danger from freezing the boiler can be filled absolutely full by removing a valve on top of the boiler to exclude all the air, and filling right up, till the water overflows from the valve. A boiler filled in this way will not rust internally. If there is danger of freezing, the boiler should be dried out thoroughly, a panful of unslacked lime placed inside and the manhole and handhole doors put on. The unslacked lime will absorb any moisture that may be present, and thus prevent any corrosion. The presence of damp soot in the combustion space of a boiler that is laid up is a source of very present danger from corrosion, and should be avoided by careful removal of all loose soot before laying up. In the case of a boiler with the stack set right above the smoke box, as is often the case in sawmill boilers, especially those with overhanging fronts, the stack should be effectually closed up, so that snow and rain cannot come down and lie in the smoke box. Summed up, the object should be to avoid any possibility of rusting while the boiler is laid up, and remember that many a good boiler has had its life shortened by many years through neglect of these simple precautions.

Regarding the length of time required to raise steam. It is as well to make this proceeding as leisurely as possible. It is not so much the danger of damaging the boiler, as in the case of a H.R.T. boiler with clean surfaces, the heat transmission and circulation are fairly rapid, but more especially the brick work should be considered. This should have a chance to warm through slowly and evenly, so that the expansion of the outside lining of fire brick and the inner rows of ordinary brick may proceed equally. There are many divergences of opinion in these matters, but with a H.R.T. boiler the writer has always endeavoured to have at least twelve hours to get steam showing. Once you have steam, you can soon bring up the pressure, but the intervening time gives a chance for a moderate fire, very little draught and a gradual absorption of heat by the mass of brick in the setting. As a contrast to this, the writer has seen a Yarrow water tube boiler, with no brick setting, brought from cold to 250 lbs pressure in twenty minutes. Scotch marine boilers, with hydrokineters or circulating arrangement from the donkey feed pump, and no brick work, are usually given from a minimum of twelve hours to a more general rate of eighteen hours, and some men give them twenty-four. On the whole would say take all the time you can get with of course an eye to the amount of coal you are going to use in keeping the boiler standing after steam is raised.

PIPE INSULATION QUESTION

Question—I have noticed in many of the smaller boiler houses copper feed water lines with no insulation. Would it be better to use wrought iron pipe or what would be the difference if the wrought iron pipe is covered?

Answer.—Copper pipe is used in feed lines chiefly on account of its non-corrosive properties. It is also lighter, and allows of being bent into shape to fit restricted positions. As regards covering it should be covered to prevent heat losses. although the relative losses between uncovered copper pipe and uncovered wrought iron pipe would probably be in favor of the copper. While copper is a better conductor of heat than wrought iron, yet wrought iron is a better radiator of heat than copper. Any pipe carrying a fluid at a much higher temperature than the surrounding atmosphere should be covered in the interest of economy.

THE GENERATION OF CRACKS IN BOILER-PLATE

In recent years cases of failure in boiler-plate have occurred which have been attributed to brittleness, although tests made before the plates were prepared for rive ing revealed no weakness of that nature. Moreover, test-pieces taken from defective plates showed, after annealing, no brittleness. Tests of the defective plates revealed in several instances a brittleness in the metal round about the rivet-holes. The authors give numerous examples of such failures. These occurrences have led to much discussion and to searching investigation. The new etching process throws light on these failures, and reveals their probable cause. Any disturbance of structure due to violent treatment of the metal, such as the shock of blows in riveting, the strain of punching, or of a bending movement—or even vibration set up by drilling bolt and rivet-holes—causes a streaky appearance in the metal, which seems to be the beginning of cracks, or at least lines along which an alteration of structure has occurred favorable to fracture. These lines are not made visible by the older processes of etching. Any violent working on the metal when cold will produce these streaks or lines which by the new process of etching, are made visible to the naked eye.

The chief interest of this article lies in the exhibition of the differences of appearance between test-pieces respectively treated by these methods. Plates exhibiting enlarged views of the different effects of the old and the new etching are given. The purpose of the authors was to afford opportunity for this comparative study. The twenty-two illustrations given not only show the effects of the new process, but also suggest the cause of many a failure of material hitherto hidden. Working on the metal in the cold has serious weakening consequences, for which a remedy has to be sought.—B. Strauss and A. Fry ("St. and Eis.")

GREASING DEVICE

A British firm has brought out a device which makes the grease filling on motor cars a simple, clean process, or at least as clean as it possibly can be. The device is fitted to the tin containing the lubricant, and has a screw with a nut which takes the form of a leather-packed piston of the diameter of the tin.

As the handle attached to the device is turned, this piston is forced down upon the grease, which is thus squeezed out of a hole in the bottom of the tin into the base of the device. From this, in turn, it emerges through a spout from which syringes, lubricators, etc., can be filled. In addition to avoiding the soiling of hands, this simple invention has the advantage of keeping the grease free from grit and dust which gathers in tins which have to be frequently opened.

The Operators' Point of View

HOW TO SPLICE STRANDED WIRE

By E. D. HUNT

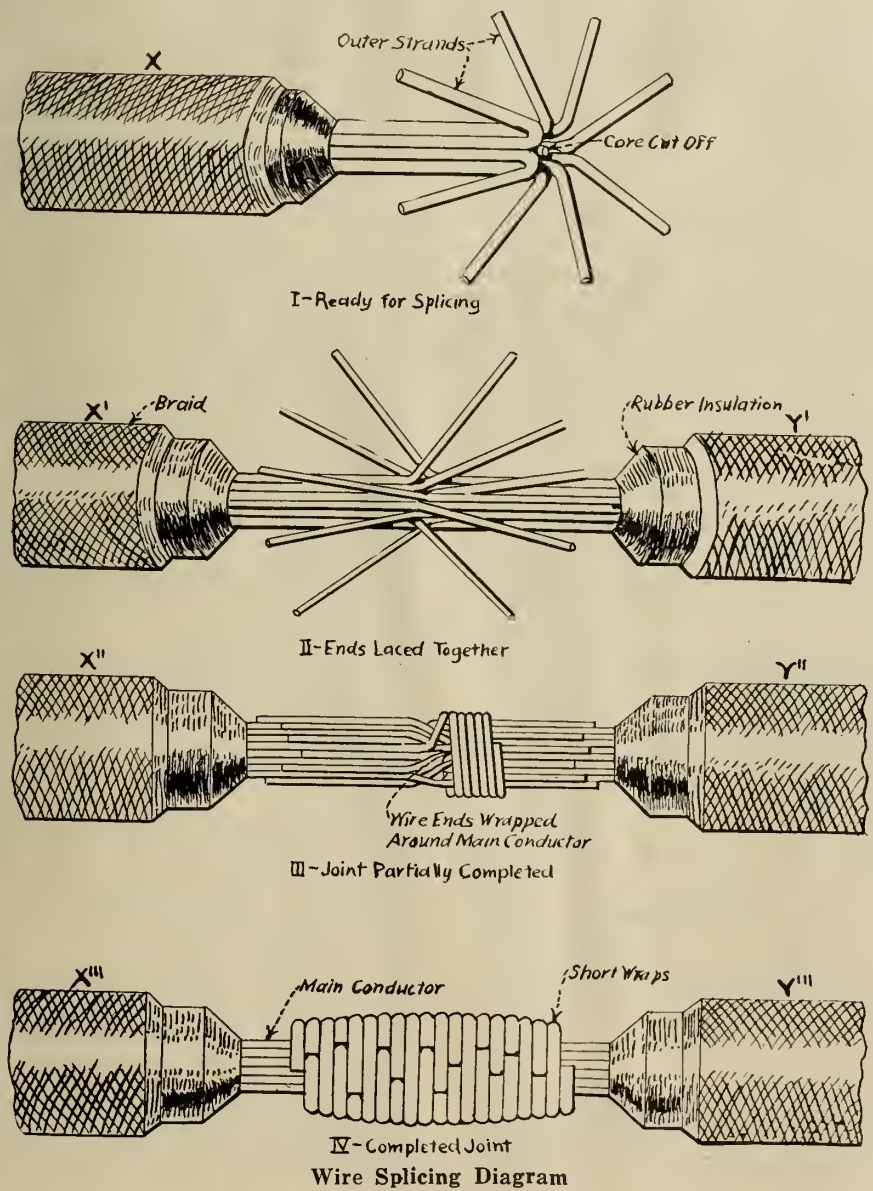
Copyright — All Rights Reserved

Almost any practical man can make a splice, between the ends of two stranded conductors, which will carry the current safely and satisfactorily but few of them, apparently, know how to make such a splice in minimum time and so that it will have a neat, business-like appearance. The accompanying picture illustrates the steps in the process which, so experience has indicated, it is best to follow. The first step is to "skin" the wire and sandpaper it until it is bright and all the rubber or other insulation has been removed from the conductor. Next the ends of the outer strands should be bent back to expose the core which should then be cut off. The end of the conductor will now appear as shown at I.

Now the outer strands which were bent back, to be out of the way so that the core could be cut off, are forced almost to their normal position. The two ends to be connected are laced together as suggested in 11, where X^1 represents one of the conductors to be spliced and Y^1 the other.

Proceeding, each one of the free ends is twisted around the main conductor, as shown at III. First, a conductor of X^{11} should be made up around the main line and then one of Y^{11}. This process is continued until all of the free ends have been served around the main line. The joint should now appear as shown at IV and is ready for soldering.

To solder it, the molten metal should be poured, with a ladle, so that it will drain into the solder pot through and around the joint until the joint becomes hot enough so that the solder will permeate it and stick to it effectively. After the joint has thus been uniformly heated and appears to be "tinned" over its whole surface a wet piece of waste can be held on it to cool it quickly. Tape servings around the joint, to the thickness of the insulation of the original wire, complete the splice.



Wire Splicing Diagram

INDICATOR CARD CRITICISM

Editor Power House

Dear Sir:

While your suggestion in regard to the card submitted in your issue of the 21st Nov., page 39, is probably correct, would not lost motion in the pencil mechanism show similar defects. Because, in the rapid fall of the expansion line, the lost motion between the mechanism of the pencil and the piston tends to make the pencil lag to isothermal, regaining normal again in the more uniform expansion towards the end of the stroke to release. One cannot criticise this card owing to insufficient data furnished, but taking the % of cutoff in either end and assuming the right side of the card to be the H.E. the % of cutoff is 24.3% while that of the C. E. is 21.6%. Investigating further and assuming a 60 lb. spring used, the M.E.P. of the H.E. works out 28.8 lbs. per sq. while that of the C.E. is 27.2 lb. per sq.

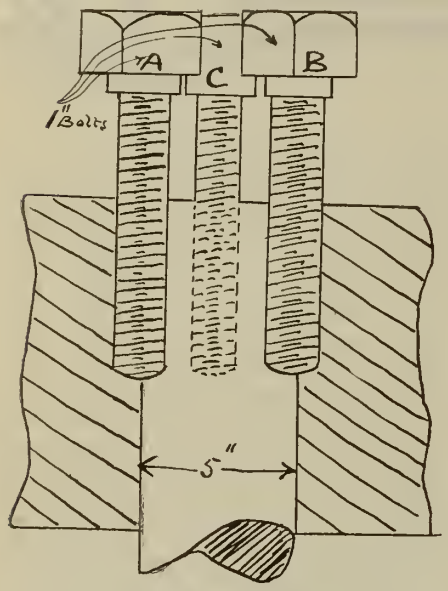
Otherwise the card is a very fair card for the class of engine but in tracing it out the sender might have avoided the mistake shown by drawing the back pressure line where it belongs, and as a suggestion, when a card is submitted as the above, would it not be possible to have it given the actual size and all available data pertaining to it furnished?

Alex. Bennett
Weyburn, Sask.

CRANK PIN REPAIR

By J. M.

A fair repair can be made on a small loose crankpin by drilling and threading three holes around the circumference and screwing in bolts as shown in the sketch at A.B.C. The bolts should be a very tight fit, and saw-



Crank Web Pinned

ed off flush with the disk after being screwed home. The diameter or the number of bolts used should be increased as the diameter of the crank is greater than that shown. With a smaller crank pin 5-8 or 3-4 inch bolts can be used.

AUTOMATIC PIT DRAINER

The sketch shows an automatic drainer easily made by any handy man. It is necessary to have a steam pressure 25 pounds or over. It will work with a high water pressure jet instead of the steam, but the results will be much less satisfactory than the steam and the discharge head will be less with water than with steam at an equal pressure.

It is obvious the outfit can be made as large or as small as desired. When a small size is wanted the tank or pit can be a box or a barrel sunk below the floor level instead of the cement tank shown. The sketch shows the float made from an ordinary 5 gallon can. The screw is removed, by filing, from the gate valve stem A, so that the seat will open and shut with a pull instead of turning the stem. The joints at B and D are rigid, they are pivoted at C and E.

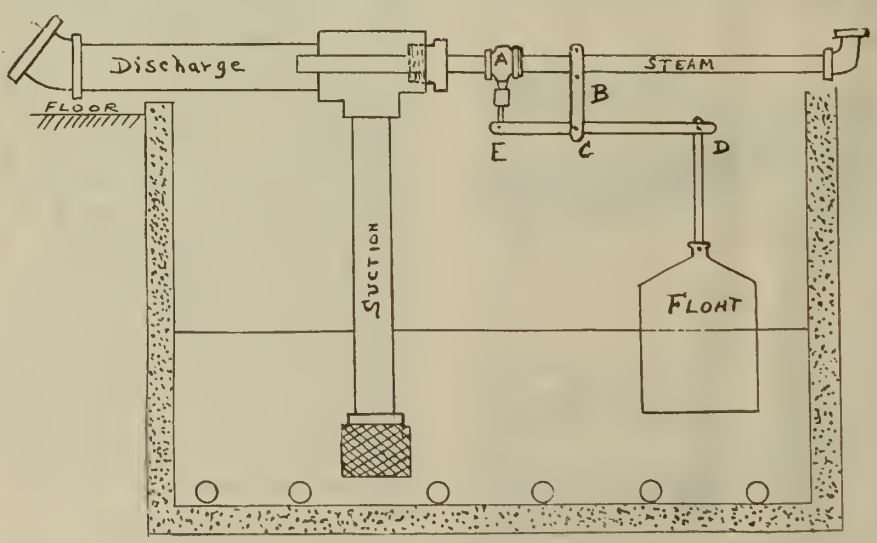
If the water that is to be removed does not flow over the top of the box from the outside, it will be necessary to leave openings in the bottom to allow entry for the water. Holes are shown along the bottom in the drawing. As the water gets to a high level the float also rises and thus opens the steam valve A. As the level of the water lowers the valve is gradually closed.

DOMINION CERTIFICATE AND OTHER THINGS

Editor Power House:

Your write-up on certificate question, in a recent issue, was right to the point and there is not a shadow of a doubt but what our certificate should be Dominion wide. As to renewal of same, this to my way of thinking, and all engineers that I have talked to, is a rank injustice. It places the engineer under a penalty to earn a living while every short while we find someone doing some work and paying nothing and getting away with it too. I believe you have the right idea so more power to your pen. I believe you have the engineers of this province solidly behind you, also, that it is our duty to write and say so. I wish to agree with J. E. Noble in his kick as to Canadian engineers not writing to our engineering journals. The shoe fits, so let's put it on. I see his letters in both Canadian and American journals, and he says some very interesting and helpful things. What have we given him in return? I also wish to thank our Editor for the course he has run in Power House. It has helped me wonderfully. In Nov. 21 issue a correspondent asks if he has sufficient power in his engines to saw 140,000 ft. per day. Yes, he has. One place I was in charge of engine and boiler room, we cut 100,000 to 110,000 feet per ten hour day, with a 400-h.p. engine. He says his engines can be pulled down with bottom saws, if so there is something radically wrong with them or the sawyer, that is if his engine is in good condition and by his cards shown in same issue, I would say distribution is very bad. If he cares to write me personally I will help him all I can. Wishing P. H. and its editors and readers compliments of the season.

W. H. Long,
Monteith, Ont.



A Longitudinal Section of Pit

LOW TEMPERATURE RETORTS

The chief requirement to be complied with in the design of retorts for low-temperature work is adequate provision for temperature contro.. The carbonization must be carried out in such a manner that neither the coal nor the vapor distilling from it is subjected to a temperature in excess of 750 deg. C., since otherwise there will be decomposition of the primary tar oils and their quality will be vitiated. Further, and herein lies the chief difficulty with which the engineer must contend, the coal must be uniformly heated and to a high enough temperature, within the range specified, to complete its carbonization. The engineer is thus restricted to the use of low-temperature gradients, and at the same time he must force heat through the poorly conducting charge with sufficient rapidity to obtain a reasonable output of products.

It will be seen that the heating problem differs greatly from that of heating high-temperature retorts. Here the temperature of the retorts, settings may be made as high as is consistent with reasonable life of refractories and economy of heating gas. High temperatures are of course conducive to rapid operation.

In the writer's opinion there is some advantage to be gained in designs based on distillation under reduced pressure provided they are not too expensive and do not lead to excessive operation costs. The same may be said of those which involve recirculation of the distillation gases. In both devices the main purpose is to remove the distillation vapors from the retorts as rapidly as they are formed and thus prevent thermal decomposition. In some recirculation devices the gas is made to give up sensible heat to the charge; all or at least a part of the heat required for carbonization is supplied in this way. The idea involved here is theoretically sound since it provides a means of getting around the difficulty of low heat conductivity of the charge and at the same time promotes uniformity of heating. The chief difficulty in applying this idea is that of economically supplying the gas with the required amount of heat, owing to its low heat capacity. Further, charges through which gases are circulated must be stirred for most efficient results and stirring precludes the formation of a well coked residue.

Toronto C.A.S.E. No. 1

HIS LODGE is keeping up the activity with which it started out at the beginning of the year. At the last meeting, which was very well attended, an interesting report from the auditors was presented, which showed a healthy state of the finances of the organization. After several members had been initiated, the educational committee went on with their work. This part of the C. A. S. E. activities is assuming more and more importance, and is being very much stimulated by means of an interesting competition which is being staged under the auspices of the Grand Lodge. A prize is being presented by the Dominion Flow Meter Co., consisting of a portable Gebhardt Steam Meter. The competition consists of a series of questions which must be answered on the floor of the Lodge, without any assistance from text books or references, and the answers contributed by the different members of the Lodge are sifted out and the best ones adopted as the answers of the Lodge collectively. The prize will go to the Lodge which gives the best answers to all the questions in the judgment of an independent examiner. We publish here a set of questions and answers which are typical of this competition. It will be easily seen what a lot of value this kind of competition will be to the members of the organization.

The movement to the new meeting hall has been a pronounced success, both from the point of view of the members' accommodation, and the added attractions for those not members but wishing to become so. A good deal of demonstrating work on the blackboard is done by the educational committee, and the members themselves, and the more questions that are brought up the better for everybody concerned.

Following is a list of the questions and answers submitted at the last meeting in connection with the competition.

Competitive Questions and Answers

Question No. 1—Give a description of three types of feed-water heaters:

(a) Open type—water either sprayed or spilling and falling and thereby coming in contact with either live or exhaust steam and thereby equalizing temperatures, at or about atmospheric pressure.

(b) Closed type—in which case the water and steam are equalized at pressures above atmospheric.

(c) Combined or indirect type in which case either or both the water and steam may be introduced above atmospheric pressure, but the equalization of temperature takes place via or through a metallic medium (shell or tubes) and the condensation in this case is usually lost because of its containing either oil or some other deleterious substance.

Note. An adaptation covering this latter scheme is often provided by taking an old H. T. B. and fitting it up with extra enclosed ends and passing the exhaust steam through the tubes and the water to be heated passing in and out of the boiler in the usual way (feed and B. O. pipe.)

Question No. 2 (a) What are the chief advantages of the use of condensed steam for boiler feed purposes?

Answer No. 2 (a) Saving in fuel and reduction of the quantity of boiler compound required if not eliminating its use entirely, as most of the impurities are removed which tend to form scale; also the saving of the heat units which would otherwise be lost.

Question No. 2 (b) What are the disadvantages, if any?

Answer No. 2 (b) Danger of oil from exhaust steam when trap or oil separator is in operation; also danger of pitting in some cases.

Question No. 3 (a) Give description of three kinds of water softeners, stating advantages of each.

Answer No. 3 (a) (1) Setting tanks for treated water (2) Soda and Lime mixing and settling tanks, (3) Permutit and other systems with combined filters.

Note. Chemicals used for treating feed water, besides those of lime and soda consist of caustic soda and various colloidal substances.

The advantages of each are as follows:—

3-a (1) Settling tanks where water contains coarse matter which is suspended but not in solution.

3-a (2) Soda and lime treatment where there is combined hardness and suspended matter.

3-a (3) Permutit system or zeolite where only hardness is to be dealt with.

Question No. 3 (b) Name some of the substances that commonly exist as impurities in feed water.

Answer No. 3 (b) Vegetable and organic matter, lime, carbonates, and sulphates of calcium and magnesium, acids and various corrosives.

Question No. 4—Give description, and point out the difference between an open (a) and a closed (b) feed-water heater, giving reasons for installation of either type.

Answer No. 4 (a) Open feed-water heaters consist of either perforated plates or trays in which case the water in falling or splashing comes into contact with the exhaust steam and equalizes in temperature also condensing the steam into water which settles in the bottom and in passing out passes through a bed of coke or other filtering material.

Answer No. 4 (b) Closed feed-water heaters:—In this type the water is circulated either inside of coils or a chamber outside of and with which the exhaust steam comes in contact and equalizes in temperature, but the product of condensation is generally lost because of the presence of excess oil or other deleterious matter, as above stated.

Question No. 5—State various boiler-feeding appliances in the order of their economy?

Answer No. 5 (1) High-pressure steam direct return traps.

(2) High-pressure steam feed-pumps.

(3) Various types of steam injectors.

(4) Indirect gravity return traps (over boilers).

Question No. 6—How may boiler feed-water be purified by live steam; and is there any apparatus in the market for this purpose? If so, describe it and cite advantages possessed.

Answer No. 6—There are several makes of feed-water purifiers on the ...pes, Webster and Dakin; however most modern feed-water heaters have the combined effect of heater and purifier.

Question No. 7—Why should advantage be taken of all sources of waste heat to increase the temperature of the feed-water heater?

Answer No. 7—Direct economy by raising the temperature of F. W., and indirect saving by preventing scale and resulting leaks and maintenance expense.

Question No. 8—What is so-called Fuel Economizer? Give sketch and description.

Answer No. 8 (1) Any device or contrivance by means of which direct economy in the use of fuel (or burning of) is effected may be said to be a fuel economizer;

(2) However the fuel economizers which are generally well known are the Greene and the Sturtevant.

(3) They consist of cast iron vertical tubes and cast iron horizontal headers.

(4) The results accomplished are indirect or secondary so far as fuel economy is concerned, comprising the absorption of what might otherwise be waste heat or excess heat in the flue gases and the results depend largely upon the varying points at which combustion takes place in a boiler or furnace.

These so-called Fuel Economizers would be better known as Auxiliary Feed Water Heaters and Economizers. They are equipped with Safety Valves, blow-out and clean out openings and generally conform to all the requirements of a Closed type of feed water heater.

Question No. 9—What are the principal sources of waste heat in connection with a steam Power Plant?

Answer No. (1) Uncovered or bare steam and hot water pipes.

No. (2) Leaks in Boiler B. O. or safety valves; also leaks in valves, traps and uncovered heaters.

(3) Tops of boilers or steam drums, and furnace walls not covered or badly insulated, cracks in brickwork, or smoke flues, reducing flue gas temperature;

also excess flue gas temperature in breeching or stack.

(4) Scale or mud deposit on heating surface or excess suspended matter entering the circulation within boiler.

(5) Loss condensation (hot water).

(6) Unexpanded exhaust or excess live steam discharged direct to atmosphere, because not required for hot water heating and no provision made for storage of excess hot water or condensate.

Question No. 10—What area of tube surface should be provided in a (closed type) feed-water heater for a 250 H. P. engine, if the steam is supplied at a temperature of 215 degrees F. and the feed water heated from 65 to 190 degrees?

Note. In calculating state of what metal the tubes are made and why not of steel or iron?

Answer No. 10—About 1 sq. ft. of tube or heating surface for each 3 H. P. of engine capacity and the tubes are best made of copper because:—1st, Copper is a better conductor of heat than either iron or steel.(2nd) Because it resists the pitting and corrosive effects of some boiler compounds better than either iron or steel.

Example: 250 divided by 3 equals 83 sq. ft. or area of heater surface required.

INVESTIGATION ON WASHING COAL

The investigation of bituminous coal washing practice in the Middle Western States, being conducted by the United States Bureau of Mines, the mining department of the University of Illinois, and the Illinois Geological Survey in co-operation, has been extended by a survey of methods in use in Alabama. The object of the work is to conserve coal resources by minimizing coal losses and to increase the utilization of Middle Western coals for coking and other purposes by reducing the sulphur and ash content. A number of coals have been examined in the field and at the laboratory in order to determine the practicability of washing them. Coals from Clay County, Ind., and from Columbiana County, Ohio, have been washed successfully. Particular attention has been paid to the cleaning of coal on concentrating tables, and to a determination of the factors that affect the washability of coal.

For the purpose of aiding the industry in securing washing plants adapted to cleaning a particular coal, data have been collected for a bulletin describing methods to be used in the examination of a coal to determine the general type of washery required.

As bearing on the difficult problem of the treatment of fine coal—a problem confronting many washery operators—a comprehensive series of tests on the dewatering of washed-coal sludge with vacuum filters has been completed and will be published.

As about one-fourth of the bituminous coal produced in the United States is used in industrial power plants, the waste of unburned coal and coke in the ashes from boiler plants has been investigated. It is possible to recover the greater part of the unburned fuel at a profit by washing the ashes on a concentrating table. A report of this work has been published as a report of the Bureau of Mines.

The investigation of the occurrence and distribution of the forms of sulphur in coal is being continued. This work is considered essential because of the depletion of reserves of low-sulphur coal, and it is being conducted with the object of rendering high-sulphur coals more suitable for metallurgical uses. Sulphur reductions obtainable by cleaning a coal depend entirely on the physical and chemical forms of the sulphur in the coal. Sulphur occurring in organic combination with the coal substance and finely disseminated pyritic sulphur cannot be removed by washing. Methods have been developed for determining the fine pyritic sulphur.

The distribution of the sulphur forms in the coal bed itself have been determined in two beds in Kentucky, one in Illinois, and one in Alabama. Organic sulphur constitutes a larger proportion of the total sulphur in coal than is generally recognized. Of 110 face samples taken in four beds, in 53 samples the organic sulphur made up more than 50 per cent. of the total sulphur. The results so far obtained have been published as Co-operative Bulletin No. 124 by the engineering experiment station of the University of Illinois.

A study of the coal-washing problems in the State of Washington is being conducted by the Bureau of Mines at the Northwest Experiment Station at Seattle, in Co-operation with the University of Washington. A special study of similar problems in the State of Oregon has been made in co-operation with the Oregon Bureau of Mines and Geology.

Representative samples of run-of-mine coal from a number of mines were tested by screening, the float-and-sink method, and laboratory washing equipment, to determine the distribution of ash impurities from the clean coal by washing, and the degree to which the quality of the coal may be improved. At the same mines samples of all washery products were tested by the float-and-sink method to determine the effectiveness of the washers as co-operating, and possible improvement of their effectiveness by the float-and-sink method of control. Many supplementary laboratory tests were made with an experimental jig and coal-washing table to determine the possibility of improving the quality of the washed coal and decreasing the loss of good coal in the washery refuse, by the use of improved coal-washing methods and equipment.

In co-operation with the mining companies the coal washeries at Issaquah, Grand Ridge, Ravensdale, and Wilkeson, in the State of Washington, and at Beaver Hill, Oreg., have been studied. All experimental work, except the supplementary laboratory tests, was done in the plants.

The principal results of the tests show: (1) The raw coal as it comes to the surface contains much bone, shale, and clay, most of which must be removed before the coal is marketable; (2) the present washeries are inefficient, the washed coal containing avoidable impurities, and the refuse containing an excessive proportion of good coal. Proper adjustment of the washers not only improved the quality of the washed coal but also greatly reduced the loss of good coal in the refuse; (3) by re-arranging present flow sheets and replacing many old machines now in use with improved coal-washing equipment, the practice at each plant could be greatly improved.

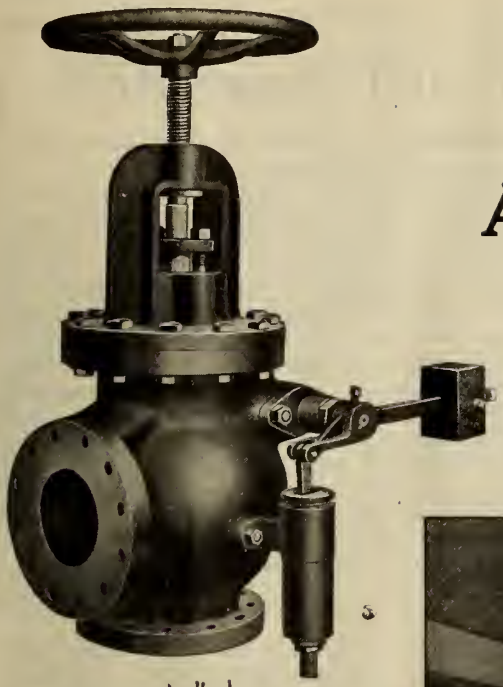
Since the completion of these studies, two coal companies have re-modeled their plants and another company has started work on a new plant to replace its present one. Based largely on results of experiments by the Bureau of Mines, one mine is building a table-washing plant to treat a pile of refuse amounting to more than 1,000,000 tons, estimated to contain approximately 200,000 tons of recoverable coal of coking quality.

Two papers are being prepared for publication by the Bureau of Mines, one on the subject of "Specific gravity studies of Washington coals and their associated impurities," and the other on "Study of coal-washing problems in the Northwest."

Tests of the froth-flotation process, now widely used in concentrating various ores, showed that clean coal can be separated from ash in material passing a 20-mesh sieve or finer. A great many coals, however, contain bone, or bony coal, in which the carbonaceous matter is so intimately mixed with ash that 200-mesh grinding does not separate them. As the bony coal is not as easily floated as the clean coal, retreating the froth concentrate of coal yields clean coal, the bone forming a "middling." By the use of this method 95 to 98 per cent. of the carbonaceous matter in the coal can be recovered in the concentrate and middling, and from 30 to 70 per cent. of the ash discarded as tailing.

Whiting Corporation, Harvey, Ill., (Chicago Suburb) has purchased a controlling interest in the Grindle Fuel Equipment Co., manufacturers of complete Powdered Coal Plants for use in connection with malleable furnaces, annealing ovens, steam boilers, billet heating and various other types of furnaces.

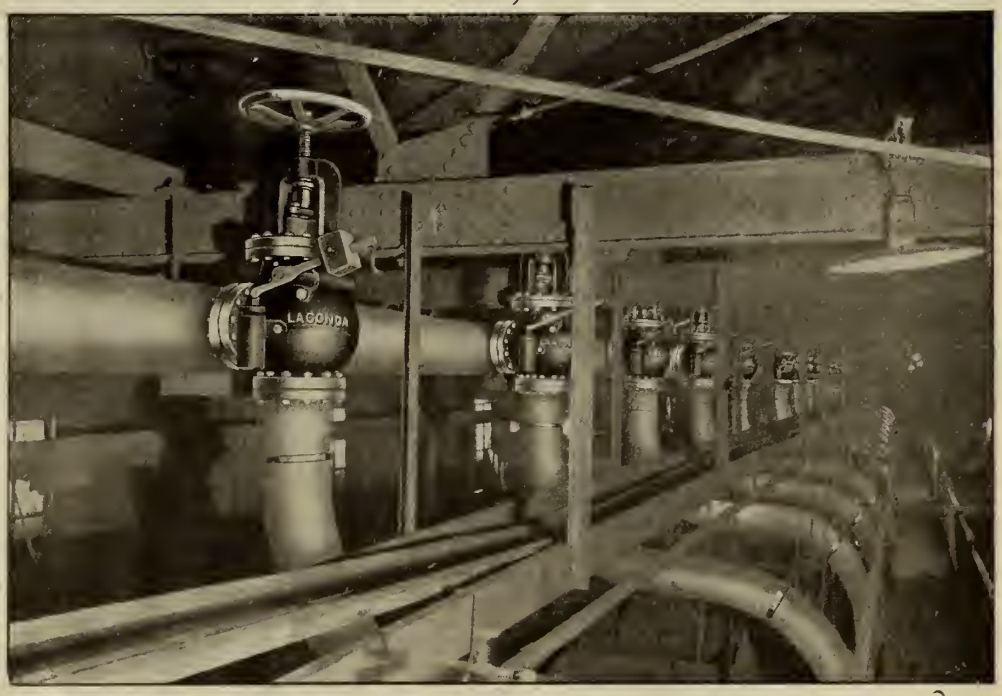
The Grindle Fuel Equipment Co. has moved its offices to Harvey, Ill., and will continue its business under the same name, Whiting Corporation, and will manufacture all Grindle equipment.



LAGONDA

Automatic Cut-off Valves

--Safeguards of the Boiler Room



Typical installation of Lagonda cut-off valve

Power Plant Equipment—
"B & W" Boilers and Superheaters
"LAGONDA" Reseating Machines
Boiler-tube Cleaners, etc.

LAGONDA AUTOMATIC CUT-OFF VALVES are essentially safety valves, protecting life and property in the boiler room. They are designed to close automatically in case of an abnormal flow of steam in either direction through the valve. They are doubly automatic and work in either direction. So serviceable have they proved under all classes of work that from Alaska to Asia the demand is *"Lagonda Valves."*

In the power house and industrial plant *Lagonda Valves* have few equals for all-round utility. In case of a tube rupture or boiler accident they at once isolate the injured boiler and prevent the other boilers connected to header from emptying through the rupture. They check live steam from entering cold boilers, prevent "lagging," automatically cut boilers in and out of service, etc.

Besides the Class "A" (external dash pot) type shown *Lagonda Valves* are made in many styles for installations in all positions.

Catalogue S-2 gives full details of all Lagonda Valves. A copy of this or data on our other lines sent free on request.

What Will Steam Locomotive of Future Be?*

THE GREATEST single item of a railway company's costs are those connected with the running of its locomotives. In the past, railway travel has developed along the lines of higher speeds and more luxurious accommodation, both of which have necessitated the building of more powerful locomotives, meaning in turn a greater fuel consumption and increased running expenses. There is no indication that the future holds anything different in store; in fact, with growing competition from other methods of travel, railways may have to offer still greater facilities than they have in the past. Mr. H. A. Ivatt once remarked that when an engine was built big enough to pull a street of houses—or words to that effect—the traffic department always wanted to couple up the schools as well. Perhaps a hotel will be now required in addition. Who knows?

Compounds And Simples

Speaking generally, continues "The Engineer," who thus speaks on the steam locomotive of the future, the locomotive, unlike other steam engines, has resisted all the efforts of those who have sought to change it from simple to compound expansion. In making this statement we do not overlook the various compounds working on the continent of Europe and in the United States, but compared with all the locomotives in the world, they form but a very small part.

The efforts of such eminent engineers as Webb and Worsdell in this country, Vauclain and Cole in America, and De Glehn and others in Europe, are still fresh in our memory, and it almost seemed at one time that through their ingenuity the compound system was in a fair way to be practically established as a real means of reducing locomotive operating costs through economies in the use of fuel and water. Indeed, there is little doubt that under certain conditions compound engines did effect some economy in fuel consumption; but certain inherent characteristics mitigated against their general adoption, the chief of which was the falling off in economy as the working speeds became higher. Under the same condition the economy of the simple engine improved, and against that fact the compound was unable to contend.

At St. Louis several different locomotives were tried on the testing plant. Amongst them were four different compounds, each having four cylinders variously arranged. Throughout the range of the tests these engines showed an economy in steam consumption per unit of power developed when compared with simple engines. The performance of the De Glehn compound, as against that of a simple Pennsylvania "Atlantic," tested at Altoona, may be particularly noted. The compound consumed at a piston speed of about 500 ft. per minute 20 lb. of steam, against 28 lb. used by the simple; but at 1100 ft. the consumption of the compound had risen to 23 lb., as against somewhat less than 24 lb., used by the simple. The Vauclain and Cole compounds, whilst they both seem to have given generally better results than the De Glehn engine, showed by their curves of water consumption the same characteristics as the De Glehn engine, a point of more than usual interest, for the French engine had four sets of valve gear enabling independent adjustment of cut-off, and the American engines were not so fitted. Of the Vauclain and Cole compounds, the former gave the best results at the higher speeds, its water rate varying from 20 lb. to 21.5 lb. at piston speeds of 650 ft. to 1250 ft. per minute, the latter figure showing an economy of 10 per cent. over the results given by the simple "Atlantic" at the same speed, while at 650 ft. per minute the simple engine required 24 per cent. more water than the compound.

The "Hanover" engine tried had, in addition to compound cylinders the important advantage of a superheater furnishing "low degree" superheated steam. The curve of steam consumption for this engine was, in character, almost exactly similar to that of the "Cole" locomotive, but at 500 ft. per minute, the speed at which it showed the least water rate, the consumption was 17.5 lb., and at 1100 ft. this figure was increased to 19 lb. At the same speed the simple engine using saturated steam showed that it required just less than 24 lb. of water per indicated horse-power.

Superheating

Since the introduction of the arch in the locomotive fire-box, no single improvement has, speaking generally, had such marked effects on the working of the locomotive from its economical aspect as the introduction of the superheater. Superheated steam has made the simple engine more economical almost throughout its entire range of ordinary working speeds than any compound experimented with on the St. Louis plant. Comparing the water rate of the superheated "Hanover" compound with that obtained with the latest type of Pennsylvania "Pacific" type locomotive using superheated steam, the results show that at a piston speed of 800 ft. per minute the water rate for the simple engine was 17.9 lb., that of the compound practically the same, about 17.7 lb., whilst at 1200 ft., 62 miles per hour, with 80 in. drivers, and 28 in. piston stroke, the water consumption of the simple engine was but 16.2 lb. against 19 lb. used by the superheated compound at 1150 ft. per minute, the highest speed at which that engine was tried. At higher speeds of 1400 ft. and 1600 ft. per minute, the simple engine gave 1 indicated horse-power for a water consumption of 15.6 lb. and 15.1 lb.

Enough has been said to show that compound engines, even if supplied with high degree superheated steam, will have to show a considerable improvement in water consumption amounting to at least 15 per cent. at the higher rates of speed before they can compete with superheated simple locomotives in express passenger service.

Superheated Compounds

From the fact that the water rate curves of both saturated and superheated compounds are generally alike in form, each displaying a similar increase in consumption with increase in speed, we gather that there is still room for improvement in the design and proportioning of compound locomotives, so far as the cylinder arrangement is concerned. Will the present pressing needs for economical working prompt designers to attempt again a solution of this interesting problem? We have on occasion seen it asserted that the express locomotive of the future will be a superheated compound, but considering the really wonderful results obtained with modern simple engines using highly superheated steam, we confess that at present we see no evidence of the re-introduction of the compound system into the practical politics of express locomotive design.

The Compounds on Goods Trains

So far we have dealt with express locomotives only. What is the position of the goods engine? Can we expect any economic advantage from the application of a superheater, and with it compound cylinders? In the United States practically all freight traffic is handled by simple engines equipped, of course, with superheaters. For very heavy "pusher" or assisting services, however, four-cylinder compound "Mallet" engines are the rule. These engines by the nature of their work operate at very low speeds, and thus appear suitable for compound working. As a result, some remarkably low steam consumption figures have been attained, and, as we write, we have before us the published results of trials made with a large compound "Mallet" built for service on the Norfolk and Western in 1918. This locomotive at 8.16 miles per hour gave an indicated horse-power for 15.21 lb. of steam; at 10.5 miles per hour, 19.4 lb.; and at 12 miles per hour, 21.2 lb. were required. These speeds correspond to piston speeds of 260 ft., 320 ft. and 385 ft. per minute.

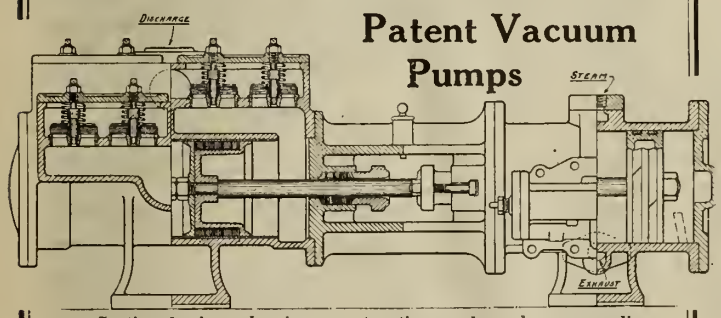
HEPBURN

Patent Vacuum Pumps



Sectional view showing construction and modus operandi.

High Pressure Packed Piston Type
—*The Last Word in Efficiency*

Combining to make this pump the most desirable for high pressure pumping are such advanced features as Self-draining Steam Cylinders, Accessible Valves, Long strokes, Absence of Screw Threads on Valve Seats and Valve Stops. Send for complete details. If you need Pumps, Cranes, Vertical Engines or Compressors investigate the HEPBURN line.

We also make the Martin Pump, and can overhaul your old pump at high speed.

JOHN T. HEPBURN LIMITED
Engineers and Iron Founders
18-60 VAN HORNE ST., TORONTO, ONT.

SARCO
INDICATING THERMOMETER
It's New-Yet Old!

While now being introduced in America for the first time, Indicating Thermometers of the Sarco type have been in successful use in France for more than ten years. The only difference between the American and the French types is the few changes we have made in order to better meet the conditions in this country.

This thermometer was designed by one of the best known authorities in the world on Thermometric design, Prof. Fournier, of the College of the Sorbonne, of Paris. Hundreds of thousands of these instruments are in use in France. The allied armies used more instruments of the Fournier type than all others combined, according to the best authorities.

The Sarco Indicating Thermometer is therefore not a new instrument—it is a proven success of the highest type. But we don't ask you to take our word for this. We are willing to ship you a Sarco Thermometer with the distinct understanding that it must give absolute satisfaction; otherwise you may return it in 30 days and the trial will cost you nothing.

One important advantage of the Sarco is that the indicating dial can be installed at a convenient point for reading any distance up to 500 feet from the bulb itself without in the least affecting the accuracy of the instrument, even when the tubing passes through a temperature greater than that to which the bulb is subjected. Other important advantages make the Sarco a thermometer worthy of your investigation. For any required range of temperature between minus 90° and plus 1,300° F.

May we send you Booklet J-151?

Roberts Water Filters

Made in Seven Styles and Sizes

VERTICAL Pressure Filters, made in seven styles and sizes ranging from 12 inches to 96 inches diameter and used in residences, apartment houses, hotels, hospitals, mills, factories and institutions. Built also in horizontal and gravity type for municipal purposes.

Style H Pressure Filter made in sizes from 30 to 60 inches diameter, for swimming pools and industrial requirements.

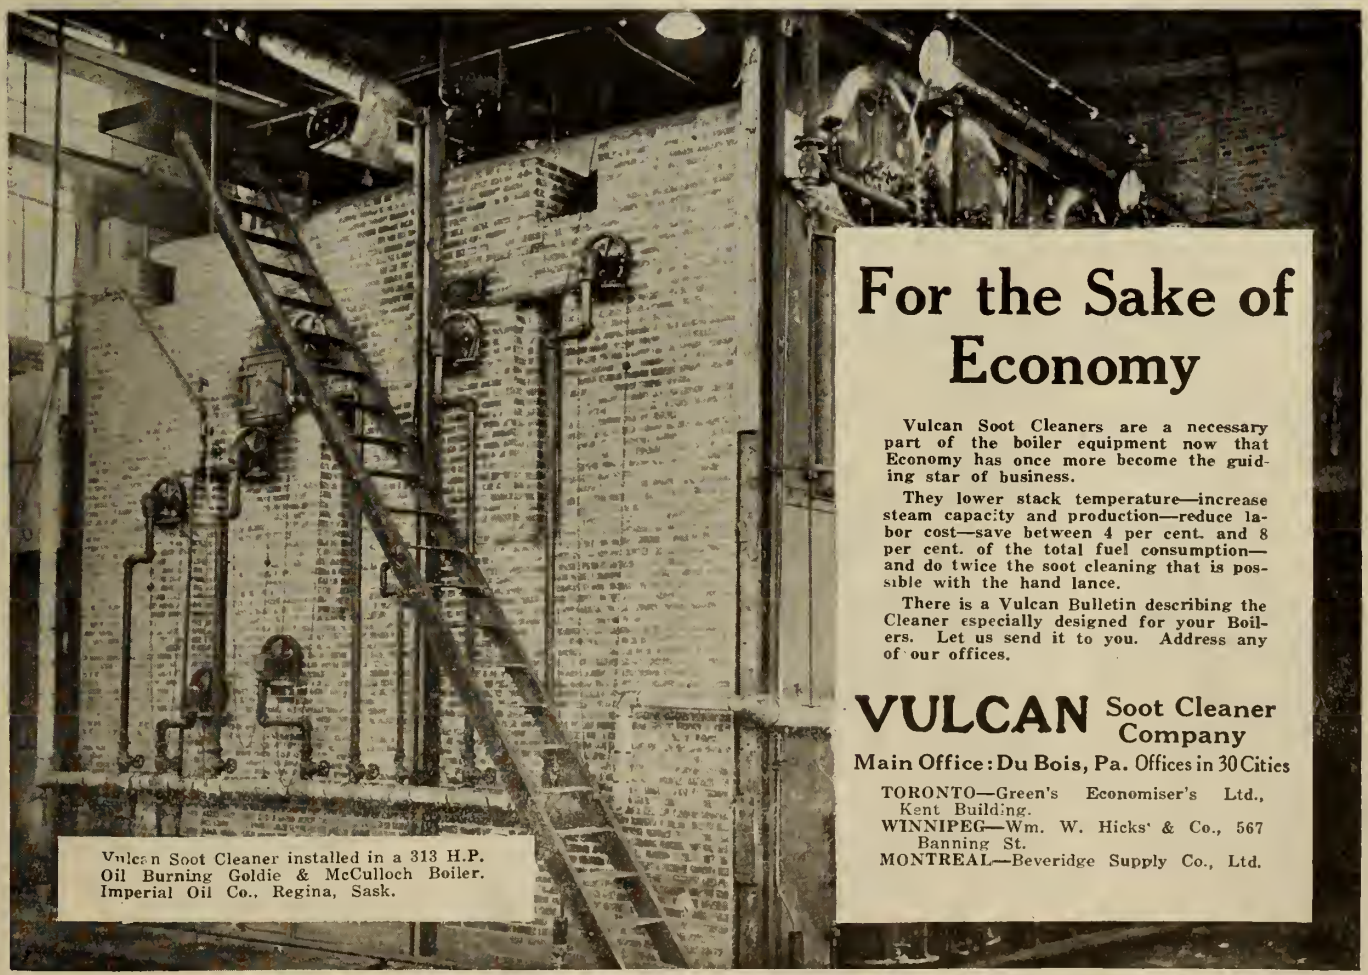
TORONTO



Vulcan Soot Cleaner installed in a 313 H.P. Oil Burning Goldie & McCulloch Boiler. Imperial Oil Co., Regina, Sask.

For the Sake of Economy

Vulcan Soot Cleaners are a necessary part of the boiler equipment now that Economy has once more become the guiding star of business.

They lower stack temperature—increase steam capacity and production—reduce labor cost—save between 4 per cent. and 8 per cent. of the total fuel consumption—and do twice the soot cleaning that is possible with the hand lance.

There is a Vulcan Bulletin describing the Cleaner especially designed for your Boilers. Let us send it to you. Address any of our offices.

Bright Spots In The Industrial Outlook

No. 6

"YOU can!—If you think you can," is a saying, the truth of which has been verified in the many instances we have given of business men who in spite of all difficulties in the present year have increased the volume of their trade. What these men have done others can do. You will sit still in vain and wait for "good times" to return. They will never return till you go and fetch them—till you do what the men of whom we have told you have done. Each man must make his own "good times." In addition to the following further instances of "Bright Spots," we are this week giving a buyer's experience which illustrates the way not to do business.

F. W. Staples, Ford Dealer, of Ingersoll, Ont., has been busy recording the best year in his business history. By sheer hard work he has sold over 80 new cars, 12 trucks, 14 tractors, 11 tractor plows, 4 sets of tractor discs and many thousand dollars' worth of accessories, to say nothing of repairs and used car sales. He enlarged his premises and added to his equipment. His 1921 business shows an increase of about 33 per cent. over that of 1920.

The Fuller Brush Co., Toronto. This company was exporting to Canada in 1920 and sales amounted to $5,000 a month. In 1921 they commenced to manufacture in Canada and sales are now $80,000 a month, and 250 salesmen are employed. The company accounts for its rapid increase in business as follows:

(1) Additional advertising — three times as strong as last year.

(2) Better type of salesman due to unemployment.

(3) People will still buy if you have value and can show it.

The organization has been tightened up in every way and selling has been made more and more intensive.

The Interwoven Stocking Co., of New Brunswick, N.J., has been so snowed under with orders that it has been obliged to confine itself to taking care of its old customers and for some time its salesmen have been instructed not to open any new accounts. During the first six months of the year more socks were sold than during the first half of any previous year in the history of the business.

John Wyckoff Mettler, president of the company, ascribes this chiefly to their bold stroke at the end of last year of practically cutting prices in half. "We figured," he explained, "that if a dog's tail has to be cut off you can't save hurting the dog by cutting it off little by little. We knew that by April we would have to have our prices cut practically in half. We decided to make the full cut at once.

"Then just as soon as we saw which way the tide was going we jumped in with an advertising campaign in newspapers in more than twenty-five cities and a series of page advertisements in color in a national medium. We invested a lot of money refreshing the public's and the dealer's picture of Interwoven. We concentrated all our forces. Now we are getting the benefit."

A STRIKING CONTRAST

Now for an experience of an opposite kind: H. W. Acason, president of Acason Motor Truck Company, wanted to buy a car. Read his account of his experiences:

Experience No. 1

"I visited one of the largest buildings in Detroit," he says, "and was quite enthused over a coupe, exhibited on a wonderful floor in a magnificent show-room, talked for half an hour with a well-dressed salesman, told him I was interested, came back the same evening with my wife, both looked at the car and both liked it. We asked to be allowed to ride in it and the salesman promised to drive the car over to our home which was about ten blocks away, and give us a demonstration. This was about three weeks ago, and I have heard nothing further from this salesman and I haven't been offered a demonstration.

Experience No. 2

"I answered an advertisement for a used coupe, went to see it twice and liked it, took my wife with me the third time and drove the car, giving the salesman my business card and telephone number. This was some time ago, and this same car is still being advertised in the papers, and I haven't even been followed up by telephone.

Experience No. 3

"I made two calls about ten days ago at one of the largest retail automobile salesrooms in Detroit and saw two different salesmen and neither one of them knew the retail price of the cars which they had for sale and each one had to go and get a book and look up the price before quoting me. Both these salesmen have my name and address but I haven't heard from them at all.

Experience No. 4

"I saw a used coupe which I thought suited me and went to the salesroom to see it and the salesman didn't even know that they had such a car for sale, let alone knowing where it was or showing it to me.

"In view of business conditions at the present time, it is hardly believable that such experiences as above mentioned can be true, but they are the facts of my own experiences, and I imagine that there are hundreds of other people who could tell the same story."

You can send your sales message throughout Canada from Coast to Coast by means of the following MacLean publications, all of which are members of the Audit Bureau of Circulations. Information regarding circulation, advertising rates and fields covered will be furnished on application.

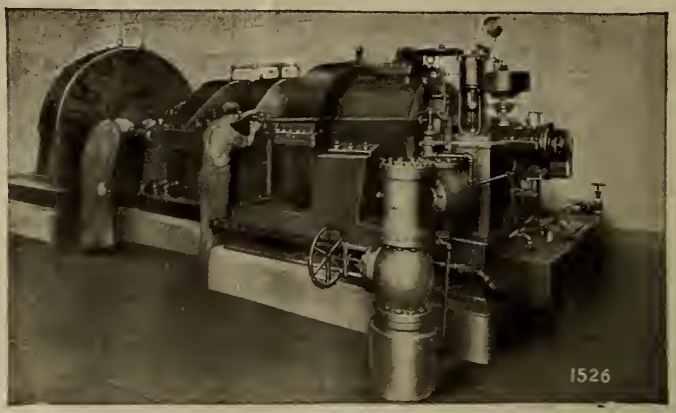
Power *For* Auxiliaries



THIS 1500-KW., De Laval geared turbo generator supplies direct current for the operation of auxiliaries in the Delray Plant of the Detroit Edison Company. The turbines operate on steam at 225 lbs. pressure and 210 deg. F. superheat. The steam is exhausted into a varying vacuum of from 24″ to atmospheric exhaust. The condenser is a barometric condenser and the circulating water used is the condensate from the main generating units.

This arrangement gives high plant economy combined with the flexibility and easy control of electric driven auxiliaries.

In such service high efficiency and reliability are paramount. Every De Laval unit is guaranteed as to efficiency and is thoroughly tested at our works before shipment. Our engineers have had extensive experience in adapting the steam turbine to increase plant efficiency and would take pleasure in applying their information and skill to your conditions.

How Much Are You Paying?

What does it cost to be without Elesco Superheaters? If you will tell us the size and type of your boilers, your present fuel consumption, power requirements and operating conditions, we can give you a very close estimate of how much it costs you each week or each month you delay the installation of Elesco Superheaters.

Operation records disclose that Elesco Superheaters save from 10 to 20% of the fuel ordinarily burned under boilers. The more wasteful the plant, the greater the saving.

By saving fuel, increasing boiler capacity, reducing condensation losses in long steam lines, eliminating water and in many other ways, varying with individual plant conditions, Elesco Superheaters effect operating economies that soon pay for the installation.

The practical suggestions of Elesco Engineers will cost you nothing and may save you many dollars of operating costs.

"Every Installation is a Demonstration of Merit"

In Choosing Steam Specialties Look Under the Surface

It is told of Alonzo Cano, the Spanish sculptor, that he once completed a beautiful statue in twenty-five days. When the man for whom he had done the work insisted on paying him by the day, Cano exclaimed indignantly: "I have been steadily at work for twenty-five years learning how to make this statue in twenty-five days."

Do not judge the value of Steam Specialties by only a superficial examination. Look into their past history. We have been steadily at work for over fifty years learning how to make Specialties that will give more efficient service. In spite of this they cost no more than those of less reliability.

Ask us for complete particulars.
